In covering so vast a field errors are almost unavoidable; nevertheless the number to be noted in Dr. Garrison's book is so small that it seems almost invidious even to mention them. It hardly seems just, however, to speak (p. 78) of Galen as "little of an anatomist." Surely the writing of such a treatise as the "*De Anatomicis administrationibus*" in the second century marks its maker as one of the greatest of anatomists! The title of Averroes' great work (p. 89) is not "*Ketab*," but rather "*El-Kollijat*," of which the word "*Colliget*" is merely a transliteration. Mention should surely have been made (p. 149) of the splendid "*Quaderni d'Anatomia*" of Leonardo, at present being edited by Dr. Hopstock and his colleagues. The discovery of the pancreatic duct by Wirsung (p. 180) was made in the dissecting room of Vesling and not in that of Vesalius. The statement (p. 602) that "twins always have the same sex" is manifestly in need of correction. There are also a few obvious minor slips, and one must regret the omission from the bibliographic appendix of such works as the excellent *Vorlesungen* of Professor Ernst Schwalbe, Le Clerc's "*Histoire de la Medicine Arabe*," Lauth's "*Histoire de l'Anatomie*" and Medici's interesting "*Compendio storico della Scuola Anatomica di Bologna*."

But such errors and omissions are of little account beside the general excellence of the work. Its thoroughness, conciseness and clearness bespeak for it the fullest appreciation from all who are interested in the past and future of medicine.

Stammering and Cognate Defects of Speech.

By C. S. BLUEMEL. 2 vols. New York, Stechert and Company. 1913.

The first volume is called "The Psychology of Stammering" and the second reviews critically many of the current systems for the treatment of speech defects. The first hundred pages of Volume I. are employed in a popular exposition of such psychological facts and opinions as the author may later need in his description of the etiology of stammering. The chapter headed "The Brain" deals rather dogmatically with some of the mooted questions of cortical localization and lacks many references to original sources. The chapter on aphasia is well handled and serves as an excellent introduction to the author's thesis that "the stammerer's difficulty is transient auditory amnesia" (p. 187). It is well shown that this amnesia attaches to the vowel sounds, especially to the more obscure ones, and that it is characteristic of the *audito-moteur* rather than of the subject possessing predominantly the visual type of imagery. We have already (pp. 98 and 103) been prepared for this position by the foregoing discussion concerning the necessary incitation for voluntary speech. This, it is held, always involves kinesthetic imagery, auditory imagery being supplementary and functioning chiefly in vowel production. Consonant production may be actuated by kinesthetic imagery alone, but not so the formation of the short and relatively "colorless" voice sounds. When the auditory imagery is temporarily lost or weakened the more obscure vowel sounds become impossible of production and stammering results. This position is strengthened both by introspection and by the records of speech cases, and if correct is of the utmost value in indicating the appropriate treatment for stammering.

Volume II. includes an excellent account of current systems of training, treated under the chapter titles: Respiration, Vocalization, Articulation, Verbal Exercises, Mechanical Appliances and Psychological Methods.

SPECIAL ARTICLES

TILTED SHORELINES OF ANCIENT CRAIGTON LAKE,
OHIO¹

Description.—A lake bed mentioned by Read,² by the present author³ and by Dachnowski⁴ lies in a mature, branched, preglacial, north and south, valley west of Wooster and east of Ashland, Ohio. The lake which occupied this bed shortly after the ice withdrew is called Craigton Lake. It may be said to center near Funk, Ashland county, and to extend in three arms, southward seven miles, northward about eleven miles and northwestward twelve miles. The main north-south axis is a little more than eighteen miles long.

That such a lake⁵ really existed is abundantly attested by beaches, cliffs, deltas, water-modified moraines and extensive flats of lake clays.

A cursory examination of the features in 1912 suggested that the beaches were not now horizontal and during the past summer careful instrumental leveling starting from U. S. Geological Survey bench marks has been done at several points along the lake plain. By this means it was found that the beach lines are far from horizontal.

The delta surfaces at the northern end are 1,040 feet above sea level. Some little wave work can be seen higher. Three miles and a half southward the beaches are at about 1,020. The altitude of 1,000-998 was found about a mile north of Funk. At Craigton the beach is 973 feet high and at the southern end we found it to be 960 feet with no wave work higher. Allowing 5 feet for possible fans or outwash deposits on the delta at the upper end, where the proper level on which to read is extremely difficult to determine, we still have 1,035 here

¹ Summary of a paper presented before the Ohio Academy of Science, at Oberlin, O., November 29, 1913, and published by permission of the state geologist.

³ Geo. D. Hubbard, *Am. Jour. Sci.*, 1908, Ser. 4, Vol. XXV., pp. 239-43.

⁴ A. Dachnowski, *Geol. Surv. Ohio*, 1912, Ser. 4, Bull. 16, p. 134.

⁵ Full description of this evidence with maps and section will appear in *Amer. Jour. Sci.* soon.

and a difference of 75 feet in 18 miles, the southern end being lower by this amount. This means a tilting upward relatively at the north with reference to the south end of about 4 feet in a mile.

Interpretations and Correlations.—The post-glacial tilting of the shorelines of the precursors of our Great Lakes has long been recognized. Very little evidence has been found of tilting south of the borders of our present lakes. The long east-and-west abandoned beaches across Ohio show almost no tilting, but lines running more nearly north and south are appreciably displaced. The evidence presented above carries actual tilting 50 miles south of the most southern part of Lake Erie, itself the most southern lake. Furthermore the rate of tilting is greater in this case than that observed on many of the abandoned beaches further north.

Goldthwait⁶ who has worked extensively on abandoned beaches to establish the amount and kind of warping that may have taken place, shows that the Algonquin beach is not tilted south of a line through the middle of Lake Michigan and Niagara Falls. In the same paper he shows that the older Iroquois beaches are tilted more than the Algonquin in the same latitudes and that the tilting extends farther southward for the Iroquois beach. He shows that the tilting is greatest further north and decreases southward, but he is unable to locate any southern limit for the tilting.

That the existence of Craigton Lake began earlier than that of any of those preceding even Lake Erie is easy to believe because of its location with reference to the retreating ice. Its site would be uncovered even before that of Lake Maumee. That tilting in the lake region began early is also shown by the fact that Craigton Lake shorelines are tilted more than such beaches as those of the Algonquin and Iroquois water planes. The warping in Craigton Lake lines amounts to four feet in a mile and is quite uniform for the 18 miles of length. It may be a little steeper in the last two or three miles at the north end

⁶ J. W. Goldthwait, *G. S. A. Bull.*, Vol. 21 (1910), pp. 227-248.

but probably is not. The apparent increase in rate is more likely due to aggradation with glacial outwash or to the building of a fan on the delta at the northern end.

Craigton not only began, but probably completed its history as a lake before the tilting occurred; a considerable part of its tilting must have occurred before the Iroquois beaches were tilted and all of it before the Algonquin was tilted, because in the first place its tilting is greater than that of the Iroquois; and in the second, Algonquin tilting did not proceed so far south. Had water remained in Craigton during the tilting, it must have spilled over southward. There can be found no evidence of static water work on the hills above the recorded beach levels at the southern end. If water stood higher here, then many tracts, low between moraine hills but higher than 960 feet, should have been under water and should attest that fact by sorted drift, lake clays, and possibly by black earth deposits of palustrial origin. Nothing of the sort can be found.

Because the outlet was in the middle portion of the lake the southern part would not be drained by the tilting. Drainage possibly fairly well established would be interfered with; swampy conditions would develop and will persist until more perfect drainage is attained. Black, peaty earth, very abundant in the southern part, confirms the belief that this end of the lake was long swampy. In fact artificial ditching has but recently put it into agricultural condition. Hundreds of acres of onions are now grown on the black flats that are sufficiently drained. Water does not stand anywhere on the plain but swampy conditions are not entirely removed.

COMPARATIVE PHYSIOLOGY

The Reactions of Normal and Eyeless Amphibian Larvæ to Light: HENRY LAURENS.

Although the photic reactions of Amphibians have been extensively investigated very little has

been done on the larval forms. The purpose of the present investigation was to test the reactions to white light of normal and eyeless frog (*R. pipiens* and *R. sylvatica*) and *Amblystoma* (*A. punctatum*) larvæ. The optic vesicles were removed from the blinded individuals at a stage of development soon after the closure of the neural folds, when the tail bud is just beginning to be perceptible. Frog larvæ, both normal and blinded, show no reaction to the stimulus of light. Both normal and eyeless *Amblystoma* larvæ, however, show a very decided positive phototaxis. The reactions of the blinded individuals are apparently not due to the direct stimulation of the central nervous system by the light as is shown by a series of experiments in which three small areas of the larvæ were illuminated, these areas being roughly the head-region, the ventro-lateral mid-body region, and the tail-region. Positive responses were obtained when each of these regions were illuminated by a narrow beam of light, the percentage of positive responses being practically the same in each case. The skin chromatophores of *Amblystoma* larvæ show different conditions of expansion and contraction of their pigment under different conditions of light and darkness; the conditions in the normal and blinded larvæ being exactly opposite. Normal larvæ placed in diffuse light are pale (light brown), blinded larvæ so placed are very dark. Normal larvæ placed in darkness are darkly pigmented (dark brown), while blinded larvæ so placed are very pale. But normal larvæ placed in diffuse light on a black background are darkly pigmented, thereby showing the effect of the background. These different conditions of the pigment in the skin chromatophores do not affect the sensitiveness of the larvæ to light, but previous exposure to light or adaptation to darkness do, in that dark-adapted larvæ are more sensitive to light than are those which have been kept in the light.

An Analysis of the Egg Extractives of Arbacia and Asterias: OTTO C. GLASER.

Analyses (1) by means of sperm-suspensions; (2) by means of qualitative chemical tests; (3) by means of the rate of development, were made. The results briefly summarized, are:

1. A general corroboration of F. R. Lillie's observations with respect to *Arbacia punctulata*; their extension in certain directions, and their application to *Asterias forbesii*. Hetero-agglutination and hetero-activation between *Asterias* and *Arbacia* were found. Agglutination is very likely the result of a surface effect.

2. Proteins, if present at all, do not necessarily come from the eggs, and are extremely dilute. Reducing substances seem to be absent. The agglutinin is heat-resistant. A purple compound, apparently specific for *Arbacia*, is formed when the sperm, the eggs or the agglutinin itself undergo certain changes. More soluble substances are secreted at the moment of fertilization than before. This, together with the fact that the volume of the eggs is smaller after fertilization, constitutes new and strong evidence in favor of the contention that fertilization involves an increase in permeability. From this it need not follow that fertilized eggs are more permeable than unfertilized. In fact this is not very probable.

3. Egg-secretion as well as egg-extract, in certain concentrations, retards development. NaOH in certain concentrations does not accelerate cleavage, but may even depress it. In the same concentrations, it accelerates the development from the blastula to the pluteus. Egg-secretion + NaOH in the above concentrations retards the cleavages much more than either used separately. One can draw no inference from these experiments as to how the egg-secretion acts in retarding development.

The suggestion that development is initiated as the result of a disturbance in equilibrium in which substances antagonistic to oxidation are eliminated is possible. It is equally possible that the removal of the substances lost allows other equally important processes to be set up. The initiation of development is identical with the initiation of cell division. For this process fertilization, even if it involves all that Lillie's theory includes, can not be considered essential, since somatic cells divide without it. This does not imply that the mechanism of fertilization may not be exactly as F. R. Lillie supposes, but the possibility that the initiation of cell division depends on other processes which also occur at the moment of fertilization remains. Neither these suggestions nor the facts on which they are based appear to the author out of harmony with existing theories. A full discussion will be published in a forthcoming issue of the *Biological Bulletin*.

Feeding Habits of Amœba: ASA A. SCHAEFFER.

The method of investigation is very simple. A very small particle of the substance to be tested was placed in the amœba's path by a very finely drawn out glass needle. Camera lucida drawings were then made at frequent intervals in order to record the behavior accurately. A large number of

substances were used: small animals and plants, isolated proteins, carbohydrates, fats, carbon, glass, carmine, etc.; also capillary tubes filled with solutions of various substances.

It was found that the amœba exercises a considerable degree of precision in selection while feeding; objects of food value being eaten while those valueless as food were rejected. However, of the substances eaten, carmine, india ink and uric acid are probably valueless as food; and of the substances refused, casein, gelatin, lecithin and zein are food substances. What the basis is upon which amœba selects its food can not be stated. But amœba eats everything that moves. If a particle of carbon or of glass or other substance is properly agitated by means of a glass needle, such particle will be eaten.

Amœbas react to objects at a distance, whether soluble or insoluble. The maximum distance through which an amœba may sense an insoluble object 20 microns in diameter is from 40 to 60 microns.

Some amœba may be led about by "tickling" with an extremely fine glass needle. A typical "food cup" may also be produced in this way.

The behavior of amœba while feeding is subject to very great variation.

Changes in Pattern and Color in Fishes, With Special Reference to Flounders: S. O. MAST.

Abstract in SCIENCE, Vol. XXXVIII., page 699.

The Reactions of the Orb-weaving Spider, Aranea Cavatica; to Rhythmic Vibrations of the Web: W. M. BARROWS. (Illustrated with lantern slides.)

It was found by using vibrating tuning forks and an electric vibrator that when one part of the spider's web is set in rhythmic motion (24-100 vibrations per second amplitude 3-12 mm.) the spider orients, advances rapidly toward the vibrating point, and attacks the vibrating instrument, even biting and throwing web on it. This positive reaction was not obtained when irregular vibrations were used as the stimulus. When a double or Y-shaped vibrator was used the spider oriented and advanced directly between the two vibrating points. The author considers this response a typical tropism and suggests the name "tonotaxis" to designate it.

Secretion in the Protozoan, Folliculina: E. A. ANDREWS.

This specialized *Stentor* secretes a transparent case of green or brown color, resembling a stocking in form. The rounded foot has one flat side

firmly fastened to some solid, the long leg rises up 45 to 90 degrees from the sole and bears on its outside a spiral ridge of six or more turns, while its mouth is completed by a reflexed lip. Three factors enter into the making of this case: the co-ordinated contractions of the body; the behavior of the cilia; a special secretion. The first factor determines the form of the case, which is then a permanent record of the secretory "instincts" of the animal. The animal first assumes the shape of the future foot of the case and secretes this about itself. Then by a special set of contractions of the anterior part it forms a mould upon which the spiral tube is made, turn by turn, with the measured elongation of the rest of the body. Finally, by an entirely unexpected change in form of the mould the lip of the mouth is added. The only part of the animal in contact with the case is the point of permanent attachment to the bottom of the case, elsewhere the secretion is laid down as a hardening mass separated from the body by the length of the cilia. As the secreting progresses from the foot up the cilia pass through successive states, at first rigid and quiet, then specially active in limiting the inner face of the case wall.

In the posterior end is a special organ, some 10 by 20 microns in diameter, associated with the myonemes.

In response to contact with solids of some kinds the posterior end puts out an adhesive secretion that, apparently mechanically, influences other *Folliculinas*, so that from the free-swimming state they commonly settle down in colonies, each with its separate case, but all fast to a common pellicle spread over the solid object or even over the surface film of quiet water.

The case is secreted when the specialized frontal field and lobes are not yet present.

The Reactions to Light and Darkness of the Melanophores of Frog Tadpoles: DAVENPORT HOOKER.

The tadpoles of *Rana pipiens* were used as subjects for investigation and some seventy-five series of experiments were performed. Each series extended over a number of days and each tadpole was subjected to a variety of conditions. The light used in the experiments was either direct sunlight or the light of a 75-candle-power Welsbach mantle. To obtain total darkness, the tadpoles were placed in blackened light-tight boxes or in an unilluminated dark room.

The following results were obtained:

1. The melanophores in the subepidermal layer of connective tissue of tadpoles respond to light and darkness in the opposite manner from those in the corium of adult frogs, with which they are identical. The former expand in response to light and contract in response to dark.

2. The epidermal melanophores do not respond.

3. The color of the background has no effect on the nature of the response in tadpoles.

4. The transition from the larval to the adult type of response takes place after metamorphosis.

5. Continued exposure to darkness produces a secondary reaction of expansion of the melanophores in the tadpole. This follows the primary reaction of contraction by an average of six hours.

6. To again obtain contraction of such expanded melanophores, the tadpole must be exposed to light.

The Movements of the Dog-fish as Determined by Olfactory Stimulation: G. H. PARKER.

A normal dog-fish, when confined in a large pool, swims more or less continuously back and forth, turning at the ends of its course. When excited by food, it courses over the bottom of the pool, turning now to the right, now to the left. This form of locomotion does not occur when the nostrils are occluded with cotton. Hence the food excitation is an olfactory response (Sheldon). When excited by food, a normal fish turns about as often to the left as to the right and generally exhibits a course like a figure eight. When only the left nostril is occluded, the fish turns predominately to the right; when the right nostril is plugged, predominately to the left. In each case the predominating turns may be as many as 90 per cent. of the total turns. These observations lead to the conclusion that, in seeking food, the dog-fish commonly turns toward the more vigorously stimulated nasal organ.

The Oxygen Utilization of Fishes: G. G. SCOTT.

Internal Pressure in Sponges: G. H. PARKER.

The internal pressure under which the current of water flows through a sponge was measured hydrostatically and found to vary in eight species of marine sponges from one to four millimeters of water. In *Spinosella sororia* an average finger discharges under a pressure of about three millimeters of water 78 liters of water a day. A colony of twenty such fingers would discharge about 1,575 liters a day, or over 415 gallons. Sponges move large volumes of water at very low pressure.

A Study of the So-called Life Cycle in Oxytricha fallax and Pleurotricha lanceolata: GEORGE A. BAITSSELL.

Further Light on the Conjugation of Paramæcium:
L. L. WOODRUFF.

This paper will appear in the *Jour. Exper. Zoology*, February, 1914.

Reactions of Amœba to Light: ASA A. SCHAEFFER.

Perpendicular beams of white and of monochromatic spectral light about 20 microns in diameter were projected through the microscope after being passed through 20 centimeters of water. The beams were projected in or near the paths of amœbas.

The amœbas reacted to these beams of light before they came into contact with them as seen by the human eye. In nearly all cases the reaction was positive, that is, the amœba moved toward the beam of light. There was very little, if any, difference observed in the reactions toward beams of white and of the various spectral monochromatic lights.

Brightly illuminated food particles were eaten neither more nor less readily than when illuminated evenly with the field; but when very slightly illuminated, that is, when laid on a "dark spot," the food object was sometimes not eaten.

Amœbas frequently move toward a beam of light in a curved path, finally coming into contact with it; occasionally the curved path extends around the beam of light so that the amœba encircles the beam for a greater or less distance without coming into contact with it. If an amœba has oriented itself with respect to a beam of light, the beam may then be extinguished without causing a change in the direction of movement. Such continuance of the direction of movement after an orienting stimulus is removed is due to "functional inertia," by virtue of which in this case the amœba tends to keep on moving in a certain direction after it is once started. No external stimuli are necessary for continuing in a straight path. The encircling of objects and of beams of light seems to be due to a balance between a tendency to keep on moving in the original direction (functional inertia) and a tendency to react positively to the stimulating object.

The Olfactory Sense of the Honey Bee: NORMAN EUGENE MCINDOO. (Introduced by E. F. Phillips.)

The Feeding Habits of Amblystoma Larvæ: H. S. BURR. (Introduced by R. G. Harrison.)

Normal *Amblystoma* larvæ use the visual sense in obtaining food when it is abundant. When the food becomes scarce the larvæ move slowly about in search of it, nosing in the débris at the bottom

of the aquarium. This characteristic reaction suggests the use of the olfactory sense.

Experimental evidence was sought to determine how great was the reliance on this sense. Normal larvæ were tested with bits of motionless beef, sand and live but motionless Daphnids. These tests resulted positively—that is they snapped at the source of the stimulus—in 91.6 per cent. of the Daphnid tests and 38.7 per cent. of the sand tests. The reactions to the beef were comparable to those of the Daphnids.

From eight 5-6 mm. larvæ the nasal placodes were removed under a binocular microscope with the aid of a pair of iridectomy scissors. When they had begun to feed, they were tested by the same methods as were the normal larvæ. No reactions to beef or motionless Daphnids were obtained. To sand they reacted positively in 60.7 per cent. of the tests.

From eight 4-5 mm. larvæ the optic vesicles were removed. These were loaned to the writer by Dr. Henry Laurens. These were tested with motionless Daphnids. They reacted positively in 98.8 per cent. of the tests.

In the sand tests, the normal larvæ as they grew older showed an adaptation, in that the percentage of positive reactions was greatly reduced in the tests of the older individuals. The noseless individuals showed no such adaptation.

Hence we may conclude that the larval *Amblystoma*, while using the visual sense in obtaining food when it is abundant, may in the absence of moving food make use of the sense of smell, and that this sense is of increasing importance to the animal as it grows older.

Experimental Analysis of Certain Processes in the Food Vacuole of Bursaria: E. J. LUND. (Introduced by H. S. Jennings.)

ECOLOGY

The Life History of the Bullfrog (Rana Catesbeiana): ALBERT H. WRIGHT. (Illustrated with lantern slides.)

Because of its size, appetite, vocal accomplishment and shyness, this species has received more attention than any other American member of the genus *Rana*. It frequents marshy bayous, button-bush swamps, mill ponds, reservoirs, glacial or sphagnaceous lakes and some marshy streams. In first appearance this species is most influenced by water temperatures. When the air reaches 68-75 (certainly 76-79), we may expect the appearance of the bullfrog, provided the water bottoms are

57-64 or average 64-69. The average date of appearance is May 20, the earliest date May 11. At the mating season the first finger of the male becomes enlarged. The type of amplexation is axillary. The breeding season extends from June 15-August 1, the average date of beginning of ovulation being June 30. The female keeps in one position more or less and lays a pancake-like film of eggs on the surface of the water. This film may be from one foot to three feet in diameter. The eggs are laid among brush, driftwood, old stumps in water, etc. During ovulation the prevailing air temperatures are from 71-80; the water maxima from 66-71. It takes only a few minutes to lay the 12,000-20,000 eggs. The jelly is loose, the animal pole black, the vegetative pole white. There is no evident middle envelope. The eggs usually hatch in 5-3 days because usually subjected to a temperature of 65-80. The tadpoles require two or more years of growth before transformation. The relative smallness of the eggs (vitelli 1.2-1.7 mm. in diameter), the late deposition of the eggs, and the greater transformation size required (53 mm. instead of the 9.6 mm. of two or more winters in the larval stage. Besides the toad)—all combine to make this form spend other characters, the best external character is the tail with regular round black spots, some of which are dumb-bell-like in shape. The belly is straw- or maize-yellow, not iridescent. Transformation comes from July 18 to August 15 or months later.

An Experimental Study of the Behavior Agreement of the Animals of an Aquatic Community:
V. E. SHELFORD.

The Relation Between Rheotaxis and Resistance to Potassium Cyanide in Isopoda: W. C. ALLEE.

The cyanide-resistance method which Professor Child worked out as a measure for the metabolic rate of planarians also holds for isopods. This is demonstrated by the effects of changes in temperature and mechanical stimulation upon the survival time in potassium cyanide; also by tests with young and old isopods, and by comparing the survival time and carbodioxide output in the same individuals. Average results from experiments on 452 isopods show that animals giving a highly positive rheotactic response have the highest rate of metabolism. Those giving a highly negative reaction are next, while isopods giving a low positive and high negative or indefinite response have a still lower metabolic rate. Isopods with a high efficiency of movement in the current have a higher rate of metabolism than those with low efficiency.

These results support previous work on this subject.

MISCELLANEOUS SUBJECTS

The Reaction of the Honey Bee to Changes in External Temperature: E. F. PHILLIPS AND GEORGE S. DEMUTH.

The Organs of Special Sense of Prorhynchus: WILLIAM H. KEPNER AND WILLIAM H. TALIAFERRO.

The organs of special sense of this rhabdole are the eyes and the ciliated pits. The two eyes lie beneath the epidermis, within the mesenchyme in depressions at the dorsal surface of the ganglia. The two ciliated pits open on the ventral side of the body anterior to the anterior limits of the surfaces of the ganglia and midway between the lateral surfaces of these cell masses and the margin of the body.

One of the unique features of these four organs is that they are formed of a definite number of cells. There are only eighteen cells involved in the formation of the four organs of special sense of *Prorhynchus*.

Each eye consists of two cells—an accessory or pigmented cell and a reticular or visual cell. The pigmented cell appears to be a modified mesenchymal cell. Its mesial cytoplasm resembles that of the typical mesenchymal cell. The lateral part of its cytoplasm, however, has assumed a definite, cup-like contour. This part of the cytoplasm, in its fixed condition, presents concentric lamellæ with which the pigment of the cell is associated. The mouth of this cup is directed laterally.

The reticular cell appears to be a modified nerve-element. Its nucleus has the characteristic spheroidal contour of a nerve-cell. In the cytoplasm, in its fixed condition, there are three regions. The lateral region is a finely granular cone that lies closely applied to the dorsal surface of the ganglion. The lateral end of this cone, we infer, is continued as a nerve-fiber into the ganglion. The basal or mesial fourth of this cytoplasmic region accommodates the nucleus. The middle cytoplasmic region of the reticular cell is the densest region. It is a concavo-convex disc. We are not prepared to say that this lens-shaped region of cytoplasm acts as a lens for converging the rays of light upon the pigment cell and rhabdome. We shall be content to look upon it as the supporting structure of the mesial cytoplasmic region, which is the rhabdome of the visual cell. The rhabdome is a low sugar loaf-shaped body that fills the cup of the pigmented cell.

The ciliated pits are invaginated regions of the

ventral epidermis, which are directed obliquely posteriorly and mesially. In the structure of each pit seven cells are involved. Six of these cells form a sensory syncytial lining or wall of the pit. These six cells are recognized by their nuclei, three of which form a dorso-ventral row in the lateral wall of the pit and three a similar row in the mesial wall. Stout cilia are borne by the general surface of the syncytial wall. This suffices for the prevalent conception of the structure of the ciliated pits of flatworms. But all of the surface of the wall of the pit does not bear cilia. Just over the middle nucleus of each side there is a well-differentiated sensory rod, so that we may look upon the wall of the pit as being formed by four accessory cells and two sensory cells. A special nerve from the ganglion runs to the posterior dorsal part of the sensory cells of each pit. The seventh cell of the pit is a large gland-cell, which crowns the widened base of the pit. The contour of this gland-cell is quite as indefinite as that of the unicellular glands of the general epidermis. Its secretion granules, however, can be differentiated from the secretion granules of the general epithelial glands by the use of Bordeaux red. This unicellular gland opens by pores through the wall of the pit at the anterior angle of the fundus.

Therefore, as we have shown in *Microstoma caudatum*, the ciliated pit is not a simple highly ciliated structure, but it is differentiated into a ciliated, sensory region and a glandular region. Thus the inferred affinity between the *Platyhelminthes* and the *Nemertine* is strengthened by the close resemblance between the structure of the ciliated pit of the former to that of the simpler cerebral organs of the latter.

The Experimental Modifications of Tiger Beetle Color Patterns by Variation of Temperature and Moisture During Ontogeny: V. E. SHELFORD.

Some Experiments on Regeneration in Thiodrilus limosus: MARY T. HARMAN.

Both the anterior and posterior regeneration has been considered. At the anterior end of any piece the maximum number of segments regenerated is six plus the prostomium. The first external indication of differentiation is the differentiation of the prostomium followed closely by the first segment. After that the segment adjacent to the old part of the worm is differentiated from the newly regenerated portion and then the segments are differentiated from the base toward the tip in reg-

ular order. Although six segments plus the prostomium are the maximum number of segments regenerated, the size of the regenerated portion and the rate of regeneration varies with the level of the cut and is independent of the size of the regenerating piece and the amount of injury.

There is, also, a region of maximum rate of posterior regeneration and this is independent of the size of the regenerating piece and the degree of injury. The amount of posterior regeneration increases rather suddenly from the head to the region of maximum rate of regeneration and then decreases more gradually toward the tail region. Pieces taken from the most posterior part of the worms do not live long and seldom show any regeneration. The direction of differentiation in the posterior regenerated part is from the base outward. However, the anal opening is soon formed. During regeneration a part of the most posterior portion of the regenerated tail remains unsegmented as a sort of segmental plate.

Will an Earthworm Regenerate Anterior Segments

When the Enteric Epithelium is Absent From the Cut Surface? H. W. RAND AND H. R. HUNT.

The Fly, Cestrus Ovis, Parasitic in Man: H. F. PERKINS.

More than a hundred living larvæ were discharged from a lung abscess in pus and mucus by a boy ill for several months. These small larvæ were identified as the early stage of the sheep bot *Cestrus ovis* and this determination has been corroborated by the Bureau of Entomology. Infection was by the mouth, the fly and the larvæ seeming to be attracted by the purulent discharges.

No case seems to have been recorded of an insect parasitic in the lung of man or any other mammal, and *C. ovis*, while it has been found in the frontal sinuses and rarely in the eyes and throat walls of man in Algeria, has only once or twice been found in man in America. The species is not uncommon in the region where this boy lives, and he took care of sheep for three years previous to his illness.

The larvæ were probably living in the abscess for at least three months, but none of them developed beyond the third stage, whereas normally they would in the same time have developed into flattened grubs of ten times the bulk, this retarded growth being attributable to the lack of oxygen in the non-functional lung.

The Effect of Alcohol on the Male Germ Cells, Studied by Means of Double Matings: L. J. COLE AND C. L. DAVIS.

Recent work has amply demonstrated that offspring from alcoholized males are commonly defective to greater or less degree, even though the mother has not received treatment and is presumably normal. Stockard's experiments with guinea-pigs have been especially conclusive, and he has furthermore shown that the effects of the treatment may persist to the second generation of offspring.

The present experiments were undertaken to test this matter with rabbits, and to take advantage of the complete control possible in double matings, that is the mating of a single female to two males at the same period, and the consequent production of offspring from both fathers in a single litter. By breeding a male homozygous for color and an albino male both to an albino female it is possible to assign the young to their respective fathers, since the offspring of the colored male will be colored and those of the albino male will be albinos. If one of the males now be alcoholized while the other is normal, and offspring from both result, any differences, such as defects in the offspring, may safely be attributed to the effects of the alcoholizing of the male, since both sets of fetuses have developed in the same uterus at the same time, and consequently there can be no question of different environmental influences.

As a preliminary test 36 double matings were made in which both males were normal. Of these, 12, or 33½ per cent., were successful; that is, young were obtained from both fathers. An inspection of the 24 matings in which the two normal males were used, but in which all the resulting offspring were from one father, shows that the individuality of the male is of more importance than the order in which they are mated to the female. Thus one pigmented male (14.1), before he was alcoholized, was used in 23 matings, an albino male being used also in each case, with the following result:

In 15 litters all the young were from 14.1, although he gave first service in only 6 cases, and followed the albino male in 9 cases.

In 8 litters young were produced from both males. 14.1 gave first service in 3 cases, and was second in 5 cases. Of the 62 offspring produced, 14.1 was the father of 38, and the albino male of 24.

So while as a result of the whole 23 matings there were 190 offspring produced, the albino male sired only 24 of them.

These facts appear to establish a strong indi-

vidual potency for 14.1. On the other hand, after he had been alcoholized (by the inhalation method), he failed to sire any offspring at all when used in conjunction with an albino male, although he was bred to the female first in at least 5 of the 7 matings made. But when he alone was bred to normal females, he sired several litters of young that appeared to be normal. There have since, however, appeared certain signs which may be indications of defects among these offspring.

Summary: There appear to be differences in the "potency" of the spermatozoa of different male rabbits. (This may be due to differential "vitality," expressed as greater or less motility, penetrating power or something of the sort.) Treating a male to the fumes of alcohol quickly lowers this "potency." Litters were born to alcoholized males (when used alone), but there are some indications of defects in the offspring.

Some Negative Results Obtained From Experiments With Fowl Tapeworms: JOHN W. SCOTT.

Ransom in 1909 mentions that we do not know the full life-history of any of the tape-worms found in American poultry. The following experiments were made in an attempt to find the intermediate host of two of three forms, *Hymenolepis carioeca* and *Davainea tetragona*. A barnyard was located in which most of the fowls were infected with one or both of these parasites. A number of chicks as soon as hatched were placed in a large screened cage and kept there until the end of the experiment. (1) To one lot of these chicks two species (not determined) of *Menopon* were fed, the lice being collected in large numbers from no less than eighteen old and young fowls in the barnyard. The idea was that, since some of the lice are usually found feeding upon the skin and soiled feathers in the anal region, the fowl might easily swallow some of them while preening its feathers. (2) Within easy access, where the fowls spent much time in scratching out "wallows" around a dung heap, were small annelids (*Helodrilus parvus*). A large number of these were fed to a second lot of chicks. (3) House flies, hatched from pupæ in a screened cage, were exposed to ripe proglottids and to feces taken from the intestines of infected fowls; on following days they were fed to a third group of chicks. Not a single tapeworm was found in any of the chicks when killed, nor in the controls. These results are reported since they appear to be conclusively negative.

Hermaphroditism in the Brook Lamprey: PETER OKKELBERG. (Introduced by R. W. Hegner.)

In a study of the reproductive organs of the American brook lamprey, *Entosphenus wilderi*, it was found that a juvenile hermaphroditic condition occurs normally and that there were three kinds of individuals as regards sex, namely, true females, true males and hermaphrodites.

The sex glands of fifty larvae, ranging from 7½ cm. to 20 cm. were studied and it was found that 46 per cent. were true females, 10 per cent. were true males and 44 per cent. hermaphrodites. In the adult condition males and females occur in practically equal numbers and the conclusion is reached that all the hermaphrodites develop into males. Out of 15 male specimens examined seven were found which contained undeveloped ova, —some a few and others a great number. These ova were similar in structure and size to those found in the larvae.

The number of ova found in the mixed gland varied greatly. Sometimes only a single ovum was found and in other cases a large number of ova were present.

The hermaphroditic condition in the lamprey seems to be similar to that found in several of the other lower vertebrates such as *Myxine*, some Teleosts, and in some Amphibians.

EXHIBITS

During the meetings the following exhibits were made by members of the society in one of the rooms of the Zoological Laboratory of the University of Pennsylvania.

E. P. PHILLIPS and GEORGE S. MUTH (Bureau of Entomology)—Instruments (Thermo-electric Outfit) (Special Scale), used in work on Behavior of the Honey Bee.

S. O. MAST (Johns Hopkins University)—Photographs and Autochromes showing changes in color and pattern in flounders.

ROBERT K. NABOURS (Kansas State Agricultural College)—Specimens and charts illustrating "Inheritance in Orthoptera."

M. F. GUYER (University of Wisconsin)—Demonstration of the X-element of Plymouth Rock Fowls.

J. E. ACKERT (Kansas Agricultural College)—Demonstration of the Innervation of the Integument of Chiroptera.

H. D. REED (Cornell University)—Model of the Pectoral and Axillary Glands in *Schilbeodes gyrius*.

CASWELL GRAVE,
Secretary

THE ASSOCIATION OF AMERICAN GEOGRAPHERS

THE tenth annual meeting of the Association of American Geographers was held at Princeton, January 1 and 2, 1914. About thirty-five members were present and the attendance of members and non-members ranged from twenty-five to sixty. Thirty-six titles appeared on the final program and twenty-eight papers were read.

The officers for 1914 are as follows:

President—Albert Perry Brigham.

First Vice-president—Charles R. Dryer.

Second Vice-president—C. F. Marbut.

Secretary—Isaiah Bowman.

Treasurer—Francois E. Matthes.

Councillors—Lawrence Martin, Robert DeC. Ward, Alfred H. Brooks.

Editor—Richard E. Dodge.

The nominating committee for officers for 1915 consists of C. F. Marbut, chairman, R. H. Whitbeck, H. H. Barrows.

One of the most important features of the meeting was the adoption by the Association of the plan of cooperation proposed by the American Geographical Society. The plan provides for (1) a joint research committee of the two organizations to administer a joint research fund, (2) a joint meeting in New York each spring, (3) the publication by the Association in collaboration with the American Geographical Society of the Annals of the Association, (4) an interchange of the publications of the two societies.

The research committee of the Association consists of: Alfred H. Brooks, chairman, Herbert E. Gregory, Robert DeC. Ward.

An increasingly large proportion of the papers read dealt with various phases of human geography. The first meetings of the Association (1904-1906) were naturally marked by a large number of physiographic papers. Then came a period (1907-1910) when physiography and anthropogeography were alternately ahead. In the last three programs anthropogeography has led, owing chiefly to the growing number of students devoted to the life side of the science. Future programs will probably show a still stronger tendency in this direction, judging by the livelier discussions evoked by the more strictly geographic papers.

The joint meeting in New York will be held April 3-4. The next annual meeting will be held at some point west of Pittsburgh.

ISAIAH BOWMAN,
Secretary

Vacuum Thermo-Elements

Made by
Siemens & Halske

The Siemens & Halske Vacuum Thermo-Elements are designed for measuring very small alternating currents, in conjunction with suitable pointer or reflecting Galvanometers. Sensibility is very high, and results of great accuracy may be obtained by their use. These instruments have been used by Public Utilities and Industrial Companies, and in University and College Laboratories. Shunts with several ranges and multi-way switches may be supplied if required.

Write for Bulletin 335, giving full particulars.

Exhibit of Scientific Instruments.

NORTHROP HIGH TEMPERATURE ELECTRIC FURNACE

FURNACE AND TRANSFORMER IN POSITION FOR OPERATION

A new type of Furnace designed by Dr. Edwin F. Northrop for his own work in the accurate determination of the resistivity of the less fusible metals and alloys in the Palmer Physical Laboratory of Princeton University. See "Resistivity of Copper in Temperature Range 30° C. to 1450° C." Journal of The Franklin Institute, January, 1914. A non-vacuum furnace for use in the many operations requiring constant temperatures up to a full 1600° C., with special reference to work above 1180° C., the temperature at which wire and ribbon wound furnaces become useless for continuous operation. The heating unit does not give off any contaminating vapors nor is it injured in the least by any metallic vapors arising from the charge. The Furnace will melt at least 37 metals and vaporize many and may be used constantly at temperatures permitting the testing of high melting point glasses and the determination of the melting temperature of the more easily fusible refractories. Its black body temperature makes it an admirable device for the calibration of optical pyrometers. Continuous heating at the melting point of palladium, 1549.2° C. requires an energy input of 2 K.W. and 1.6 K.W. will give a final temperature of 1250° C.

Price of Furnace only with unit and accessory equipment.....	\$360.00 net
Price of Special Transformer, operating on either 110 or 220 volts. Other primary windings on application. With secondary voltage regulated in six steps and with a total capacity of 4 K.W. for continuous operation....	\$165.00 net
Price of extra graphite Heating Units with terminals.....	\$ 35.00 net

MICROSCOPES, LABORATORY AP-
PARATUS AND CHEMICALS

West Washington Square,
PHILADELPHIA

A New Invention

The Leitz "Binocular Microscope with one objective"

This instrument causes quite a revolution in the Microscope technique.

The Binocular Microscope can be used with low and high powers, including Oil-Immersion.

The body contains a system of prisms whereby the binocular vision with the aid of two oculars is effected. A milled head allows the oculars to be placed at the proper distance to suit the interpupillary of the observer's eyes. One ocular is supplied with an adjustment for the accommodation of the difference of refraction between the eyes of the observer.

FEATURES

Restfulness to both eyes.

Image of increased brilliancy is resolved into the minutest details.

Apparent stereoscopic effect especially noticeable.

The regular objectives, available in the laboratories, can be utilized.

Price complete, without optical equipment, duty free \$79.30

Three New Books

Mallory's Pathologic Histology JUST OUT IN 20 SCHOOLS

Dr. Mallory presents *pathology* biologically. First he ascertains the cellular elements out of which the various lesions are built up; then he traces the development of the lesions from the simplest to the most complex. He so presents pathology that you are able to trace backward from any given end-result, such as sclerosis of an organ (cirrhosis of the liver, for example), through all the various acute lesions that may terminate in that particular end-result to the primal cause of the lesion. The book is based on the study of the *lesions themselves*. There are 683 illustrations, 124 in colors.

Octavo of 677 pages, with 497 figures containing 683 original illustrations, 124 in colors. BY FRANK B. MALLORY, M.D., Associate Professor of Pathology at Harvard University Medical School. Cloth, \$5.50 net; Half Morocco, \$7.00 net.

Davis' Nasal Accessory Sinuses JUST ISSUED

This book is based on the study of 290 lateral nasal walls, presenting the anatomy and physiology of the nasal accessory sinuses from the *sixtieth day of fetal life to advanced maturity*. It represents the *original research work* and personal dissections of Dr. Davis at the Daniel Baugh Institute of Anatomy of Philadelphia and at the Friedrichshain Krankenhaus of Berlin. In order to complete the series Dr. Davis had to develop a *new technic* by which the accessory sinus areas could be removed *en masse* at postmortem, and still permit of reconstruction of the face without marked disfigurement. The *tables of averages* give you the age, size of ostia, origin, thickness of septum, and anterior and posterior walls, vertical, lateral and posterior diameters, and relation to the nasal floor.

Octavo of 172 pages, with 57 original illustrations. BY WARREN B. DAVIS, M.D., Corinna Borden Keen Research Fellow of the Jefferson Medical College, Philadelphia. Cloth, \$3.50 net. 3 REAMS.

Wells' Chemical Pathology JUST OUT THE NEW (2d) EDITION

This work deals with the chemical changes which take place in pathologic conditions. It treats of the *causes* of disease, and so provides the first step in their *treatment*. It discusses the cell (proteins, ionization, colloids, osmotic pressure, etc.), enzymes, nature and action; autolysis; chemistry of bacteria and parasites and their products; immunity, agglutinins, precipitins, toxins, antitoxins, phytotoxins, zootoxins, hemolysis, serum cytotoxins, inflammation, blood diseases, edema, retrogressive processes (necrosis, cloudy swelling, gangrene, rigor mortis, various degenerations, etc.); calcification, pigmentation, tumors, metabolism, uremia, gout, diabetes, auto-intoxication, ductless glands (thyroid, adrenals, hypophysics, thymus, etc.).

This new edition is right up to date.

Octavo of 616 pages. BY H. GIDEON WELLS, PH.D., M.D., Associate Professor of Pathology, University of Chicago. Cloth, \$3.25 net.

You should send for a copy of our new 88-page Illustrated Catalogue

W. B. SAUNDERS COMPANY Philadelphia and London

New McGraw-Hill Books

Published March, 1914

Physics for Technical Students Mechanics and Heat

By WILLIAM BALLANTYNE ANDERSON, Ph.D., Associate Professor of Physics, Iowa State College. 349 pages, 6x9, 150 illustrations, \$2.00 (8/4) net, postpaid.

Professor Anderson has prepared this text on Mechanics and Heat under the general title of "Physics for Technical Students." He has aimed to present the subjects from the practical side for the great number of students preparing for work in engineering and agriculture.

Special attention is given to the treatment of Force, Torque, Translatory Motion and Rotary Motion, because these underly so much of the subsequent work of the student.

GEOLOGY AND MINERALOGY

Published Sept., 1913

Lindgren—

Mineral Deposits

By WALDEMAR LINDGREN, Professor of Economic Geology; in charge of the Department of Geology, Massachusetts Institute of Technology; formerly Geologist of the U. S. Geological Survey.

882 pages, 6x9, fully illustrated, \$5.00 (21s) net, postpaid.

A description, by classes and type examples, of the occurrence, structure and origin of the principal deposits of metallic and non-metallic minerals.

It does not attempt to cover coals, hydrocarbons and structural materials. Little space is given to statistics, while the problem of correlation and origin are treated fully.

"A book of undoubted significance; one which is likely to mark a definite change in the current of study."

Published Feb., 1914

Daly—

Igneous Rocks and Their Origin

By REGINALD ALDWORTH DALY, Sturgis-Hooper Professor of Geology, Chairman of the Department of Geology, Harvard University.

563 pages, 6x9, 205 illustrations, \$4.00 (17s) net, postpaid.

This book is planned to meet the needs of those who desire either a general explanation of igneous rocks, or the more significant facts about them.

Part I is a summary of these facts, with a number of contributions thereto, a large part of which can be described quantitatively.

Part II treats of these facts in the light of the earth problem as a whole.

Part III treats them in relation to the comprehensive theory outlined in Part II.

Published March, 1914

Johannsen—

Manual of Petrographic Methods

By ALBERT JOHANNSEN, Ph.D., Assistant Professor of Petrology, The University of Chicago.

649 pages, 6x9, 765 illustrations, \$6.00 (25s) net, postpaid.

There is no work in English which gives complete information on modern petrographic-microscopic methods. Dr. Johannsen has filled this gap with a work of broad scope, requiring years of research and labor.

It is designed as a reference work for specialists and a text book for advanced students.

Send for full descriptive circular.

I

A COMPARATIVELY brief period has passed since the evidence brought together by Darwin in connection with the results slowly accumulated from other sources has clearly demonstrated that the diversity of organic life in the world occurs through evolution. It is one thing, however, to clearly diagnose a condition and quite another to understand the causes which have brought about the phenomenon so that similar results may be produced advantageously. With the assumption that evolution was merely the survival of those forms which were best adapted to the environment, generation after generation, the explanation of the method as well as its practical application, namely the improvement of organisms in any given direction, was apparently a simple matter. It seemed evident that man had modified and adapted to his welfare various plants and animals by a more or less unconscious and haphazard selection long before history records civilization.² Why then could not civilized man carry forward the work and with the knowledge gained since the principles of evolution were recognized, obtain far-reaching results within a brief period of time. All that seemed necessary was to have individuals

¹ Presidential address before the twenty-third annual meeting of the Ohio Academy of Science, Oberlin, O., November 28, 1913.

² One need not be a pessimist to assert the actual evidence thus far obtained indicates that the supposed progress made in the improvement of domesticated animals and plants is nothing more than the sorting out of pure lines and thus represents no advancement.

of a particular organism in large numbers, and by continued selection of the variations best meeting the conditions move rapidly forward by a series of increments toward the goal of perfection. What could be more simple? Instead of corn having an acreage yield of fifty bushels, there would with a proper supply of plant food be a production of two hundred, two hundred and fifty or even three hundred bushels. Instead of politicians with no perspective beyond their immediate welfare—a reelection—instead of college presidents and faculties with their numerous shortcomings—according to the students and occasionally the trustees—there would be the ideal individual bred to specification and not necessarily made in Germany.

Unfortunately, variations with a perverseness incomprehensible uniformly refused to accumulate in the manner desired and at times even demonstrated their obstinacy by retrogression. It was plainly evident that there were limits imposed by nature not easily passed, and in connection with which much experimental work must be undertaken before definite progress was made and the facts fully understood.

With a realization of the difficulties involved in an attempt to apply evolution, it will be well to pause for a moment and consider certain fundamental principles before discussing the results of some of the investigations which for a time at least promised much toward the solution of the problem. Thus it may be stated that evolution in its different modifications postulates in general (1) the occurrence of numerous varying individuals, some of which are (2) eliminated by environmental stimuli leaving few or no offspring, while (3) the survivors transmit to their progeny the characters which proved of selective value, with the result that (4) through the continuation of the process the race eventually becomes

adapted to surrounding conditions. The first two propositions are merely statements of fact. The real difficulties of the situation are those of ascertaining how variations which are transmitted may be recognized and produced so that the result will be a cumulative one. Until this is done breeders must continue to proceed in the same haphazard manner that they have followed for countless generations.

By selecting the largest and most perfect ears of seed corn from the variations present in the field, conversely eliminating the remainder from reproducing, the corn grower plants with a fatuous trust in providence that a crop somewhat better or at least as good as the preceding crop will be produced. If it is a type comparatively pure the average may be maintained and the hope partially realized, but the chances for retrogression are far greater than for advancement, inasmuch as there is no means for distinguishing a variation which will be transmitted with equal or better results than in the preceding generation, from one that represents a fluctuation due to nurture and which is non-transmissible. Thus the apparently inferior ear of corn will frequently produce a yield far better than obtained from one which is perfection as graded by the methods of the "corn show," and if from the same pure race, the resultant crop will be at least as good. Artificial methods of hybridization, which furnish an immediate advancement in the succeeding generation, result in a gain which is only temporary. The increased stimulus to growth vanishes as a fluctuation.

Thus it is quite evident that there exists a problem in the evolutionary control of organisms even the partial solution of which will mark an extraordinary advancement not only for agriculture, horticulture,

and animal breeding, but also for society in general.

II

The general results of the investigations bearing upon the evolutionary control of organisms may be grouped around the principles of Mendelism, the mutation theory, and pure line breeding.

The rediscovery in 1900 of the fundamental laws governing hybridization so brilliantly established by Mendel in 1865, but unfortunately concealed in the obscure publications of the Natural History Society of Brunn, opened an extraordinary field for experimental work. This has already developed to vast proportions in connection with both the results obtained and the speculations involved, while the end is not in sight.

The investigations of Mendel, now so familiar to all biologists, and which may be mentioned somewhat in detail here because of their bearing on mutation, consisted primarily in the crossing of tall and dwarf peas, with the result that the first filial (F_1) or hybrid generation consisted entirely of tall plants. When, however, seeds from these plants were sown the ratio of tall to dwarf plants became 3 to 1 in the second (F_2) hybrid generation, a result explained by the theory of dominant and recessive characters on the basis that there are certain determiners of unit characters in the germplasm which dominate over others during the development of the somatoplasm or body of the individual in the higher forms of life. More recently the presence and absence theory has been applied in interpreting the results. In a manner similar to the preceding when smooth yellow peas were crossed with wrinkled green peas the first hybrid generation consisted of smooth yellow forms inasmuch as the character smooth and the character yellow were dominant over the character wrinkled and

the character green, and the crosses were known as dihybrids, inasmuch as they differed in respect to two characters. In the second hybrid generation the resultant ratio was 15 to 1 pure recessive, *i. e.*, wrinkled green, although the fifteen consisted of smooth yellow, smooth green, and wrinkled yellow in the proportion of 9:3:3. In the same way trihybrids have the ratio 63 to 1 pure recessive while any polyhybrid differing in "*n*" characters which mendelize in the usual manner will give an expected ratio of $4^n - 1$ to 1 pure recessive, which will become apparent only through the breeding of large numbers of individuals.

While the preceding summary represents the normal results in connection with the segregation of unit characters, studies of the past few years have demonstrated that many interesting relationships may occur between the factors governing the production of characters. For example, it has been found that two or more determiners are often present either of which will produce the given character as Nilsson-Ehle demonstrated in hybrids of brown and white chaffed wheat, while on the other hand two or more determiners acting together may be necessary to bring about an effect. Such a condition exists, as Bateson in 1910 showed, in certain white-flowered sweet peas which when crossed produce purple flowers in the first hybrid generation. The results which have led to the theory of coupling and of repulsion, particularly the latter, where the expectancy of a pure recessive may be one among many thousands, go far toward suggesting a possible explanation of many so-called mutations on the basis of ancestral individuals heterozygous for one or more characters.

Do the Mendelian principles assist us, however, in attaining the goal which we are seeking, namely the building up of an ideal

organism which will continue to transmit its characters? The answer must be in the negative so far as the originating of anything new is actually concerned. Recessives may be obtained. Characters may be redistributed. They were present in the forms first utilized, however.

The mutation theory formulated by De Vries in 1901 approximately at the time interest was being awakened by the rediscovery of the hybridization principles of Mendel, needs no extended explanation to those who have been interested in evolution. Based on cultural experiments with *Oenothera lamarckiana*, one of the evening primroses, the appearance of relatively small numbers of forms which were quite distinct from the parental species and which bred true in subsequent generations, led to the inference that evolution had in many cases proceeded by discontinuous variations or mutations.

Long series of breeding experiments followed in connection with other organisms, both plants and animals, with results quite similar to those obtained by De Vries. Investigations were also made (Fischer, MacDougal, Tower, etc.) where organisms were subjected to stimuli abnormal in their nature, with the result that a modified progeny was obtained which bred true to the apparently induced character in succeeding generations. Furthermore, cytological studies (Gates, etc.) demonstrated some interesting relationships so far as different "mutants" were concerned.

While the evidence is far too insufficient to allow more than a tentative opinion, there are several conclusions concerning mutation which appear justified. The nature of the results obtained through the various agencies make it quite evident that they are not all due to a single underlying principle. There are many "mutants" the origin of which is most certainly to be explained on the basis of a heterozygous

condition of the gametes, and much evidence has accumulated that *O. lamarckiana* of De Vries on which the mutation theory was founded belongs to this class. Furthermore there are mutants developing in connection with the action of abnormal stimuli although it is not at all improbable that some of these result from heterozygotes. It may be mentioned that Humbert (1911) in experiments with 7,500 pure line plants of *Silene noctiflora*, one of the "pinks" utilizing methods similar to those of MacDougal, failed to obtain any "mutants." Another explanation of the results in connection with the influence of abnormal stimuli is that the modification takes place through the destruction of a factor and thus the process is one of subtraction instead of addition. There are also investigations, notably those of Gates, in which the aberrant organism apparently results from the abnormal behavior of the chromosomes at some stage during the life cycle. *Oenothera gigas* with its tetraploid chromosomes is here of much interest.

Notwithstanding these diverse results, there is little indication that anything actually new has been added to the organism which would not have occurred within a pure line. If this is true the heterogeneous school of mutationists can be of little assistance beyond suggesting the way in which evolution did not take place.

The experiments on the basis of pure line breeding belong to a comparatively recent period and are of the utmost importance. Johannsen in 1903 published results based on a pure line of beans self-fertilized for successive generations and evidently homozygous. From a bean weighing 95 centigrams and far above the average in size he obtained plants producing beans varying in weight from approximately 35 to 70 centigrams, but all far below the weight of the parent. Utilizing

these in turn as parental forms, from those having a weight of 35-40 centigrams there resulted a progeny with an average of 57.2 centigrams, while from those having a weight of 65-70 centigrams a progeny was obtained which had an average of 55.5 centigrams. In other words, selection had not only failed to make any advancement, but actually resulted in a slight retrogression. Facts quite in accord with this but giving much more pronounced results have been obtained by Tower (1906), Jennings (1908), Johannsen (1909) and others. It should be noted, however, that there have been several experiments, notably those of De Vries with buttercups, Tower with potato beetles, and Smith with Indian corn, where a possible advance of a character was recorded in a group. Heterozygotes here may have been responsible for the result, although again the explanation may consist in the elimination of the effects of a determiner.

The results in mixed races as exemplified by corn, beans, etc., where selection has gradually improved a group of organisms but finally reached a limit beyond which no progress appeared possible, are comparatively well understood and are due, as explained by Shull (1908), to the separation of the pure lines which were present in the race at the beginning. This is where the average agriculturist, horticulturist, and animal breeder has gone far astray and, having succeeded for a few generations in making progress, has failed to understand why he may not continue to be successful.

Thus we find that attempts to modify a character by selection within pure lines within a small number of generations have almost universally failed, and that the few apparent results to the contrary must be looked upon with the suspicion that the population was a mixed race and that Mendelian principles applied.

Once again we are led to propound with still greater emphasis the question, "How then has evolution taken place?" "In what manner have organisms acquired their characters?" "Is it possible to escape the difficulties that confront the investigator on every side?"

III

The application of statistical methods to problems of biology has provided and will continue to provide facts of decided value obtainable in no other way. Nevertheless, the use of data "en masse" uncoordinated with experimental methods can not solve the riddle of existence so easily as some, at an earlier period at least, would have had us believe. There are, however, investigations which seem fundamental to the problem under discussion and which may well be approached from the statistical side. These relate to the influence of certain factors composing the environment as well as to the part played by asexual and sexual reproduction, corresponding in reality to close and cross breeding, upon variability and size in organisms.

Some studies undertaken in 1900 in connection with the influence of food supply on variability³ based upon the comparison of groups of *Chrysanthemum leucanthemum* L., the common white daisy, as well as *Perca flavescens* Mitch., the yellow perch, indicated that the difference in variability as evinced by the coefficient of variation for a group with a maximum food supply as compared with a group having a minimum food supply, was extremely small and well within the limits allowed by the probable error. From this the inference was that external stimuli played an extremely unimportant part under normal conditions as a cause producing variability in general.

Attempts were subsequently made to ob-
³ SCIENCE, p. 728, 1907.

tain data bearing on the results of close breeding and cross breeding which differ merely in degree from parthenogenesis and amphimixis. The question is an important one, for if cross breeding is only valuable in sorting out and combining existing characters, it not only obscures the facts, a knowledge of which is necessary before progress can be made in building up new characters, but results in no actual advancement in cumulative evolution. Here the material for study consisted of scalariform or cross-bred and lateral or close-bred (parthenogenetic) zygospores—in reality the young individuals—of the common filamentous green alga *Spirogyra inflata* (Vauch). Upon applying statistical methods the close-bred zygospores were found to be 23 per cent. more variable⁴ in size as well as larger, both in length and actual volume, than the cross-bred zygospores. The results were not in accord with the general belief that cross breeding increased variability, although studies by Warren, Kellogg, Casteel and Phillips had pointed out that this belief was not substantiated by facts, which, however, did not actually warrant the idea that variability was decreased in cross-bred forms. The studies on the zygospores also suggested that sex existed primarily for the purpose of limiting variability, a hypothesis proposed on purely theoretical grounds by Hatchesek in 1887. Another conclusion which followed from the same investigation was that in connection with the origin of death⁵ and which may be mentioned here. This is summarized by stating that death apparently occurs as the result of the continually forming body cells becoming so variable through absence of control by amphimixis, that eventually some one group of functional importance fails to meet the

limits imposed by the environment. In consequence of this the group, together with the remainder of the colony—the individual—perishes.

In connection with the difference in the variability of close-bred and cross-bred zygospores it seems quite evident that the result is brought about by some factor other than the environmental stimuli which are assumed to produce fluctuation, inasmuch as the material was homogeneous in every respect with the exception of the manner of reproduction. The question is a difficult one, however, not to be settled by a single investigation giving positive results, and because of its importance should receive attention.

In reference to those who hold to the belief that cross breeding, conjugation and amphimixis—the three terms differ merely in degree—increase variability, it may be well to inquire concerning some of the evidence which has been instrumental in formulating the opinion. Without any desire to be critical and at some risk of exceeding the controversial bounds which a paper of this nature allows, a few of the more important investigations touching upon the subject will be considered.

Castle, Carpenter, Clark, Mast and Barrows (1906) in a series of observations as to the effect of cross breeding and close breeding on the variability and fertility of the small fruit fly, *Drosophila ampelophila* Loew., stated that “inbreeding did not affect the variability in the number of teeth on the sex comb of the male, nor the variability in size,” basing the opinion on the coefficient of variation in the number of spines and the standard deviation in the length of the tibia. In the former case the data certainly do not permit a clear conclusion one way or the other, but the value of the character which represents the sum of the teeth of the sex combs of the right

⁴ SCIENCE, p. 907, 1908.

⁵ SCIENCE, p. 935, 1912.

and left proximal tarsal segment, where there is undoubtedly correlation, may be open to objection under any consideration. If, however, from the data presented in the study the value of the coefficient of variation is computed, which, strange to say, was not done in the paper, and thus allowance made for the greater length of tibia in the cross-bred forms, the combined inbred forms exhibit a variability relatively 68 per cent. greater than the cross-bred forms.

Jennings (1911) in summarizing breeding experiments with *Paramecium* concluded that "The progeny of conjugants are more variable in size and in certain other respects than the progeny of the equivalent non-conjugants," and farther, "Thus conjugation increases variation." Continuing the investigations, he subsequently stated (1913) that conjugation increased the variation in the rate of reproduction. While the careful methods used by Jennings have brought to light many interesting and valuable facts, it is evident, from a critical consideration of the data, that they by no means allow such conclusions.

So far as size is concerned in a pure race, non-conjugants and their progeny were more variable than conjugants and their progeny, as noted in Table No. 28. In a wild race the progeny of the conjugants were slightly more variable than the progeny of the non-conjugants, as illustrated in Table No. 32, although in two of the nine generations tabulated the variability was greater in the case of the non-conjugants. So far as the rate of fission is concerned, the evidence is unmistakable that the conjugants were more variable. There is, however, a comparatively simple explanation for this when the statement is noted that the number of abnormal individuals, as well as the mortality, was greatest among the progeny of the conju-

gants. With a considerable number of forms thus having a lower rate of fission, one could expect nothing except a greater variability in the rate of fission. This becomes the more evident when it is found that the higher variability of the conjugants was caused by the considerable number with the low rate of fission.

Considering the data obtained in the breeding of plant forms where the assumption has long been prevalent that hybridization increases variability, it is found that the variability of the F_2 generation as compared with the F_1 generation or a single parental generation may be increased, but that the actual variability as a whole is not increased when the united parental types are taken into account. This may be illustrated by utilizing data from an interesting paper by Hayes (1912) dealing with correlation and inheritance in tobacco. Here, calculating the constants for two parental types combined (401 and 403) in respect to number of leaves and height of plant, it is found that the coefficient of variation has decidedly decreased through the hybridization, although the number of combinations have increased.

There exists the possibility, however, that variability will appear to be increased when forms having the same phenotype but different genotypes are bred together. Such a condition may be illustrated by the two white strains of sweet peas crossed by Bateson which produced purple flowers in the first (F_1) hybrid generation, and purple, pink, mixed, and white flowers in the second (F_2) hybrid generation. New combinations occur, but there is no evidence of increase in unit characters, nor is there an actual increase in variability.

Turning for a moment to size characters, the influence of cross breeding or conjugation is of decided interest inasmuch as facts bearing on the solution of the problem as to how size may be increased to the phys-

iological limit, even though the results hold for a single generation; have the greatest practical value for the future of agriculture and animal breeding.

It should first be noted that size in a unicellular organism is dependent on the absolute size of the individual cell with a limit undoubtedly imposed by laws governing the ratio between volume and surface in connection with osmosis. In multicellular organisms, however, size characters may depend upon either the size or the number of the component cells or upon both factors. This distinction possibly explains an apparent diversity in results obtained in the two groups.

Darwin, Mendel and others who have seriously considered the question have recognized that hybrids, among plant forms in particular, usually grew to a larger size than either parental form, a result probably due to the increased rapidity of cell division and consequently greater number of cells as conjectured by East. In the study of zygospores of *Spirogyra* it was therefore noted with some interest that the cross-bred forms were smaller than the close-bred forms so far as both length and volume were concerned. Jennings (1911) in his study of *Paramecium* reached a contrary conclusion, stating that "The progeny of conjugants . . . were a little larger than the progeny of non-conjugants and the difference appears to be significant." This is correct merely in reference to length, however, and that it is not true for actual size as indicated by volume is evident on applying the formula for the volume of a prolate spheroid ($V = 1/6\pi ld^2$) by which it may be demonstrated that the non-conjugant forms, while smaller than the others at the beginning of the experiment, actually became larger. Thus in agreement with the zygospores of *Spirogyra*, conjugation decreased size.

The question immediately occurs as to the cause of the increased size and vigor among cross-bred multicellular organisms when the evidence indicates that cross-bred unicellular forms are smaller instead of larger. Some investigations that I have undertaken indicate an answer apparently meeting the conditions. While sufficient control experiments have not been made to venture more than a provisional opinion, the data suggest that the cells of cross-bred multicellular organisms are actually smaller than the cells of inbred or pure line forms, and that the more rapid division is a function of the greater ratio surface has to volume in a small cell with the better opportunity thus obtained for increased metabolism.

That there is need of further investigation on size and variability in pure lines and in cross-bred forms through the application of statistical methods in connection with the maintenance of pedigrees through long series of generations seems evident. Eventually theories will make way for facts which will allow a proper perspective.

IV

Where do the results presented in the preceding pages lead us? Does their value, so far as their bearing upon the production of new and transmissible characters that will build up an organism in a required direction, consist merely in the formulating of hypothesis after hypothesis which as investigations proceed will in turn make way for other hypotheses equally transient? Or, on the other hand, do they mark a definite progress along the lines we are endeavoring to follow, namely, the control of evolution.

Before attempting a reply which must prove more or less unsatisfactory to those looking forward to immediate results, it seems advisable to pause for a moment and in the light of the preceding discussion con-

sider the types of differences—variations—which exist in so far as they may effect the result with which we are chiefly concerned.

Beginning at an early period in the history of evolution with the idea that all variations might be inherited, results soon suggested that the characters due solely to surrounding influences such as food supply, etc., were not thus transmitted. These were called *fluctuating variations*. On the other hand, variations due to the structural changes in the germ cells which were passed on from one generation to another have been spoken of as *inherited variations*.

The evidence at present indicates that farther subdivisions must be made and that normal inherited variations consist of two quite distinct classes. The variations where the results are due to the interaction of factors in accordance with Mendelian principle, and which, adapting a term used by Plate (1913), may be called *amphimutations* inasmuch as the condition is due to the mingling of two lines of descent, the other variations, as a class, in which the results—evolution in the abstract—are due to a series of units added as increments, may well be called *cumulations*. It is quite evident that the term "mutation" can not continue to include both types. As a coordinate term fluctuating variations may be spoken of as *fluctuations*.

Under abnormal variations must be classified forms ranging from monstrosities to slight departures from the ordinary condition, some of which are undoubtedly due to the losses or modifications of unit characters through the action of extraordinary stimuli, while others may be due to abnormal and unequal distribution of chromosomes occurring at the time of their division. The *idiomutations* of Plate are here included.

The answer to the question as to the progress made in the application of evolution to the creation of new forms rests in

the statement that the attack on the problem is becoming more concentrated. The selection of fluctuations has been tried and has failed. Efforts by means of amphimutations end in a maze of circles with no evident progress. *Idiomutations*, so far as one may judge from the evidence, present retrogression rather than advancement. It is by means of pure lines under normal conditions that one may search with advantage for cumulations, the units by which to build the new. There the evidence will be unobscured either by the pyrotechnics of Mendelian formulæ, or by the factitiousness of abnormal stimuli. Fluctuations will be present, but statistical methods will permit their evaluation. Should the measurement of the mean in the tenth or even the one hundredth generation present no advancement, failure is not necessarily implied. Nature has devoted fifty millions of years or more to her work. There should be no discouragement if a few paltry years of investigation fail in duplicating her methods.

It is with a feeling not unmixed with pessimism, however, that one views the conditions under which work of the character outlined must evidently go forward. Those engaged in teaching have with a few exceptions time for little more than an occasional investigation of limited scope, particularly in a field which requires continuous application. Governmental departments where it could best be taken to a successful issue have only too often been subservient to political policies which demand immediate results. An ounce of compiled compendium is—to them—worth more than a ton of painstaking investigations which makes an advance on a theory. Looking a few generations into the future is not their concern.⁶ A remedy for such conditions clearly

⁶ Exceptional work has been done by those more or less closely connected with certain State Agricultural Experiment Stations. The names of East and

lies in endowments either in connection with universities, or through the establishment of the specialized private institution.

That the problem of applied evolution will eventually be solved there can be no doubt. That it will occur in our generation may only be expressed as a hope.

L. B. WALTON

KENYON COLLEGE,
November 15, 1913

THE MUTATION MYTH

It has long been recognized both on the botanical zoological sides, that sterility is a notable characteristic of species crosses or true hybrids. Where species are nearer to one another their resultant cross is naturally less sterile than when their affinity is more remote. In the case of plants it is usually particularly easy to trace even slight evidences of previous hybridization in the sterility and abortive character of some of the spores or pollen. In contrast to hybrids, genetically pure species are characterized by pollen grains or spores, as the case may be, which are all perfectly developed. I have satisfied myself by a very extensive study of the spores and pollen of liverworts, mosses, ferns (including numerous genera of all the important families, isosporous and heterosporous), lycopods, selaginellas, quillworts, lepidodendroids, equisetes, cycads, ginkgo, conifers (including numerous genera of all the tribes), gnetales (all the genera) and many dicotyledonous and monocotyledonous angiosperms, that in good species the spores or pollen is invariably perfect morphologically, that is fully formed and having normal protoplasmic contents. Known hybrids on the contrary are characterized by a greater or smaller number of abortive spores, which have little or no protoplasmic contents. Hayes, of Connecticut, Pearl, of Maine, Emerson, of Nebraska, Dean Davenport, Rietz and Smith, of Illinois, are familiar to all interested in the application of the principles of evolution. One often conjectures, however, as to the extent to which some of the most valuable contributions are in reality "by-products" of investigations meeting the approval of the "Missouri" type of legislator.

This conclusion is by no means new but the wide range of facts examined in the present connection adds very materially to its strength. It has been further noted that so far as morphological conditions are concerned, plants of genetic purity, even when grown under extremely abnormal conditions, as exotics in greenhouses, etc., have perfect spores or pollen. For example a conifer or a cycad from Australia or Japan, grown in the hothouse and producing its pollen in the winter season, still shows the grains normally developed morphologically, whatever may be their physiological inefficiency.

The bearing of the facts indicated in the paragraph above is of great importance in relation to the mutation hypothesis of De Vries. This distinguished Dutch plant physiologist, a little over a decade ago, published a series of observations and generalizations under the title of "Die Mutationstheorie." His notable offering was the statement that material of a species of *Oenothera* or evening primrose, referred by him to Seringe's *Oenothera lamarckiana*, found growing spontaneously near Hilversum in Holland, was producing annually new species or as he preferred to call them, elementary species. In 1904 Professor De Vries was invited to lecture in the University of California on his sensational discoveries. The lectures were edited and published later by the director of the Desert Laboratory of the Carnegie Institution of Washington, with the title of "Species and Varieties, Their Origin by Mutation." Dr. MacDougal thus became both in fact and figuratively, the "vox in deserto clamantis," the baptist of the gospel of mutation. His exploits with the syringe in the baptism and production of new species of plants by intra-ovarial injections appear further to render his claims in this direction beyond question. As secretary of the Botanical Society of America and by his repetition and elaboration of De Vries's cultures of *Oenothera*, he has done unquestionably more than any one else to diffuse the doctrine of mutation in North America. It has in fact become so widely accepted on our continent, that it has in many instances

been unfortunately introduced even into elementary courses of botanical or biological instruction. Europe has presented a marked contrast to America in this respect, for here the mutation hypothesis of De Vries has been coldly received. It seems clear however that the European attitude is more in accordance with the established principles of biology than our own.

The distinguished English geneticist Bateson was apparently among the first to point out that in all probability *Enothera lamarckiana* was a hybrid, as shown by the partial sterility of its pollen. Dr. MacDougal countered by the statement that he had found abortive pollen in specimens of *O. biennis*, growing in the vicinity of the city of New York. This he apparently regarded as a sufficient reply to Professor Bateson's criticisms. More recently a number of American students of plant genetics have cast doubt on the genetical purity of De Vries's *Enothera lamarckiana*. Among these may be mentioned Davis, East, Emerson and Gates. The attitude of the last investigator is not the less significant because he was in the first instance a convinced mutationist of the De Vriesian school. In the case of the mutation hypothesis, we find again what is apparently an all too common condition in the case of biological theories, a neglect of fundamentally important morphological evidence. There seems to be absolutely no doubt, on morphological grounds, that not only is *Enothera lamarckiana* of hybrid origin; but that the *Onagraceæ*, to which it belongs, are somewhat generally contaminated by spontaneous hybridism.

I have delayed publication of my conclusions in regard to the genetical status of the *Onagraceæ*, in the hope that some other morphologist would lay bare the extremely insecure foundations upon which the imposing superstructure of the mutation hypothesis has been raised. About eight years ago cultures of *O. lamarckiana* and its mutants were started at the Harvard Botanic Garden from seeds supplied by Professor De Vries. *Enothera grandiflora*, which was of special interest in connection with the mutation hypothesis, was

likewise grown from seed supplied by Professor S. M. Tracey who made a special visit to Tensaw to obtain it for me. Shortly afterwards other work became more pressing and monopolized all available time. The cultures and seeds were accordingly turned over to Professor Bradley M. Davis, who was residing in Cambridge at that time. Dr. Davis has published a number of papers on hybridization work with *Enothera* species and I have supplemented my original stock of preserved material from specimens kindly supplied by him.

Some illustration of pollen conditions in known hybrids other than *Onagraceæ* will first be considered. Many of our improved horticultural plants are known to have originated by hybridization, while others more anciently cultivated by our species are suspected of hybrid origin. Taking only the known hybrids as illustrations, such as tulips, irises, narcissus, lachenalia, freesia, etc., etc., we find that although many of the pollen grains are perfectly developed both as regards external form and internal contents, a greater or smaller proportion are small, shrivelled and nearly or quite devoid of protoplasm. In the case of genetically pure species of these genera the pollen grains on the contrary are all alike and perfect. In normal species, even when long in culture and under hothouse conditions the pollen has proved in all the cases examined in the present connection perfectly sound. This is notably the case for example with the common easter lily. The effect of hybridization is equally clear in the case of the *Dicotyledons*. Our pinks, calceolarias, nasturtiums, etc., are often of known hybrid origin and show clear evidence of such derivation in the condition of their pollen, which is more or less abortive. President Brainerd, of Middlebury College, has in recent years made some interesting observations on spontaneous hybrids of our native violets. He has found numerous forms of these, significantly described by certain systematists as new species, to be in reality hybrids, as shown by their characters clearly intermediate between recognized species and by their Mendelian segre-

gation in cultures. Professor Brainerd has been kind enough to supply some flowers of these interesting specimens for the present work and the pollen conditions are clearly those found in hybrids.

We may now profitably turn our attention to the Onagraceae, to which the well-advertised *Enothera lamarckiana* belongs. Our common garden fuchsias are known to be of hybrid origin. In some of the varieties the pollen sterility is almost complete. This is notably the case in a hybrid derivative of *Fuchsia triphylla*, grown in the Harvard garden. In other varieties the sterility is often less marked. This condition has been found to obtain for example in long-tubed fuchsia hybrids. Here a certain number of the grains are perfectly developed and have normal protoplasmic contents, while others are small, shrivelled, collapsed and without protoplasmic contents. Among the wild-growing species of the Onagraceae, those of *Epilobium* have long been recognized by European systematists as prone to produce spontaneous hybrids. A good illustration in the present connection is supplied by a hybrid form of *E. hirsutum*, occurring commonly in the vicinity of ballast heaps. Here the pollen is to a large extent abortive, the degeneracy sometimes affecting the whole of the contents of the anther sack or in other cases being confined to a greater or smaller number of the grains. In contrast to *E. hirsutum* may be mentioned our common fireweed, *E. angustifolium* (sometimes put under a different genus). In all the abundant material of this species examined the pollen was entirely normal. Indications of hybridization correlated with corresponding pollen conditions have also been noted in the case of other representatives of the Onagraceae, but the illustrations mentioned will suffice for our present purposes.

We may now turn to the genus *Enothera* itself. In his "Mutationstheorie" De Vries has noted that about one third of the pollen of *O. lamarckiana* is sterile, and abortive. This statement I can only confirm. Even in the more vigorous of the so-called mutants originating in cultures of *O. lamarckiana* from

the seed, the pollen is very largely degenerate and in the less vigorous elementary species often almost completely so. In *O. lata* (mutant of *O. lamarckiana*) the pollen is frequently entirely sterile. But it is not only in *O. lamarckiana* and its so-called mutants or elementary species, that pollen sterility is to be seen, for this condition is well nigh universal in the species of this Onagraceous genus, recognized in systematic works. For example in the very common and variable species known as *O. biennis*, half of the pollen grains are sometimes abortive. This condition I have observed in specimens from regions as far apart geographically as the state of Massachusetts, the province of Ontario and the shores of the Gulf of St. Lawrence. The examination of a large amount of material of recognized wild species of *Enothera* has led me to the apparently inevitable conclusion that spontaneous hybridism is extremely common in the genus and that in general it represents a condition of high genetical impurity. The purest species which has come under my notice, so far as may be judged from the pollen conditions is *O. grandiflora*, obtained from Tensaw. Here pollen abortion is well nigh absent both in flowers gathered for me by Professor Tracey and in those produced from seed both by Professor Davis and myself. Continued growth in the Harvard botanic garden has not altered this characteristic in any degree, for specimens grown last summer show the same condition of relative genetical purity or at least freedom from inharmonious hybridization.

It may be argued by some that the more or less marked constancy of the generally accepted species of *Enothera* makes it clear that they are normal species. It is now recognized however that constant hybrids are of extremely common occurrence both in nature and as a result of experimental crossing. This is particularly true of species crosses. There is consequently no good reason why we should not admit that the genus *Enothera* is strikingly characterized by spontaneous hybridization. There appears in fact to be every reason to believe that the bar sinister has been crossed and double crossed in our American

evening primroses. The extensive studies which I have made on the pollen and spore conditions in the higher plants from the mosses upwards, which will be detailed and illustrated elsewhere, make the conclusion apparently unavoidable, that the *Onagraceæ* in general and the genus *Enothera* in particular, are peculiarly subject to spontaneous hybridization in nature. It follows of course that no genus or group of plants could have been more unfortunately chosen to illustrate the origin of species by mutation or saltatory evolution. Obviously we must in the light of the considerations advanced above, interpret the variability of the seedlings of *Enothera* species, particularly of those of *O. lamarkiana* of De Vries, as evidence of ancestral hybridization, on the evidence of the very significant pollen conditions revealed both by the genus under discussion and by many members of the family to which it belongs.

The mutation theory of De Vries appears accordingly to lag useless on the biological stage and may apparently be now relegated to the limbo of discarded hypotheses. The zeal, industry and insight of the distinguished plant physiologist of Amsterdam can not be too highly appreciated. Even although his hypothesis must apparently be given up both on morphological and genetical grounds, it has nevertheless been the cause of a great deal of valuable work, which will remain after the motive of it has disappeared. The present refutation has been undertaken in the interest of biological progress in this country. It is now high time, so far as the so-called mutation hypothesis, based on the conduct of the evening primrose in cultures, is concerned, that the younger generation of biologists should take heed lest the primrose path of dalliance lead them imperceptibly into the primrose path to the everlasting bonfire.

EDWARD C. JEFFREY

HARVARD UNIVERSITY

DEMOCRACY IN UNIVERSITY ADMINISTRATION¹

A DISCUSSION OF THE topic assigned to me in this conference might be as brief as the fam-

ous chapter on snakes in the Natural History of Iceland, or, to use a more modern instance, as a review of Mr. Taft's activities in subversion of the courts and the constitution. There is no democracy in university administration. But we can consider the conditions and the remedies.

The situation of a teacher has aspects inherently undemocratic. He has arbitrary authority over the conduct and intellectual life of his students, and is paid by superior officials to discipline and teach as they prescribe. The professor may lecture to his classes "als dictirt euch der heilig' Geist," and in other academic relations may realize that silence is silver and flattery gold. To be half tyrant and half slave does not strike the average of a free man. The pedagogue may be expert in his narrow field, while he is segregated from the larger life of his fellow men. His salary is safe and small; his clothes are black and threadbare; he is very respectable, but only half respected. The inevitable difficulties we emphasize by providing on the one side a system of education which does not carry its own appeal and must be enforced by examinations, grades, degrees, compulsory attendance and the like, while on the other side a system of administration has developed which puts the professor in a position of personal dependence. He is not only unfree in the sense of the domestic servant, whose wages, work, company, habits and Saturdays off are set by the employer, but he is also unfree in the sense of the slave in that he is held to his place by forces that he can not resist. This may be in part caricature, like the typical professor of the novel or play who hunts beetles, while his daughter or wife engages in flirtation, but a caricature may depict and enforce the truth.

A less obvious but equally undemocratic aspect of the academic career is due to the fact that the university professor earns his living by teaching and the conduct of academic routine, while society depends on him

¹ Read at the conference on "The Relation of Higher Education to the Social Order," arranged by the council of the Religious Education Association, Yale University, March 5, 1914.

for productive scholarship and scientific research. Three quarters of the scholars and men of science in this country hold academic positions. Services to individuals can be paid for by those benefited, but we have no machinery in a democracy by which services to society are paid for by society. Public service can thus be rendered only by those who can spare the time, and is rewarded by recognition, reputation, honors, etc. Under aristocratic institutions men of inherited wealth may serve without salaries as members of parliament, magistrates, university chancellors, scientific men, scholars and the like, and may have their reward in social recognition, titles, membership in exclusive societies and similar non-rational sanctions. These by-products of oligarchy are its historical justification; responsibility for public service is placed on those who have wealth and privilege. But in a democracy power and wealth, in so far as they are desirable, should be the rewards of public service, not its prerequisites. Trustees of universities and members of school boards who serve without salaries are likely to render services about equal in value to the payment they receive.

Amateur work, whether by the man of wealth or by the teacher, becomes increasingly ineffective as the boundaries of knowledge are enlarged. The university instructor, impelled by sheer love, carries on a research, getting the time by working between hours and after hours. But he can not complete it or put it in its place in the orderly development of the science. He hopes to do so in the summer, but family bills accumulate, and he must engage in the sweat-shop labor of the summer school or some hack work. The research becomes cold, perhaps something of the same sort is done elsewhere, it is published in a slovenly way or not at all. I have somewhat recently had the privilege of visiting the Bureau of Standards, the Rockefeller Institute for Medical Research and the Research Laboratories of the General Electric Company. Here we have three institutions, conducted, respectively, by the government, under private endowment, and by an industrial concern, be-

side which the laboratories of physics, chemistry and physiology in our best universities are distinctly amateurish and inferior.

The men in these institutions have larger salaries and better facilities for their researches than are given in the universities; but their great advantage is that they are investigators by profession paid directly for the work they do. The professor, paid for his most important work in the fiat currency of reputation and petty honors, is in a position completely undemocratic. It is no wonder that we have the *demitasse* storms of academic politics and social life. There is one thing more absurd than for professors to march in processions in the order of their dignity advertising by brightly colored gowns and hoods the degrees they have received, and that is to make the financial reward of scientific and scholarly work transfer to an executive position which prevents doing such work thereafter.

The undemocratic aspects of our academic life are almost wantonly enhanced by the position attained by the president with the ensuing hierarchy of deans, heads of departments and other officials. The extraordinary material development of the country, with no balanced aristocratic system, has led to excessive power in the hands of a few individuals, whether in politics, in business, or in educational work. Every sensible person believes in individual initiative and individual responsibility. The safety in a multitude of counselors is usually due to the one who does the job. Government is a rough business, and this holds to a certain extent for educational institutions. The university or college president must do the best he can under hard conditions, and it is no wonder that he takes as much power as he can get. He has at least six masters—the trustees, the faculty, the students, the alumni, the general public and the bearers of the purse—not to speak of his wife's social and his own political ambitions. Each of them has different and discordant interests and ideals. It is not surprising that he finds it troublesome to ride these various horses and sometimes

. . . moves in a mysterious way
His wonders to perform.

The difficulty is that if an autocrat obtains unlimited powers, whether in the nation, the state, the city, the family or the university, he does not always prove to be wise and benevolent, and it may even be argued plausibly that the wise and benevolent despot is the worst kind, for he works the greatest demoralization. It is true that in a democracy we can afford to give large power to our leaders, for they are subject to the popular will. In the British democracy the monarch can only be permitted to be a social ornament, as he is there for life and his son after him. In our American democracy the president of the nation has extraordinary influence, but he can only maintain it so long as he reflects public sentiment. In Great Britain the cabinet is directly responsible to the parliament, and represents in its constitution the diverse elements of the majority, the prime minister not being necessarily the one most influential. This method is more democratic than ours, and in my opinion preferable. We have tried it with tolerable success in the commission form of government adopted by a number of cities. This is also at the present time being used in several colleges and universities, but not much can be expected here so long as it is a temporary expedient to last only until a president can be found.

It may indeed be seriously questioned whether the superior initiative and efficiency which one-man power is supposed to have is not more than counterbalanced in a university by the loss of these traits in the subordinates. A superman requires as his correlative many undermen. It is almost impossible to supervise the teaching and research of professors. Such an attempt is charmingly portrayed by President MacLaurin of the Massachusetts Institute of Technology in connection with the report on academic efficiency of the Carnegie Foundation:

The superintendent of buildings and grounds, or other competent authority, calls upon Mr. Newton:

Superintendent: Your theory of gravitation is

hanging fire unduly. The director insists upon a finished report, filed in his office by 9 A.M. Monday next; summarized on one page; typewritten and the main points underlined. Also a careful estimate of the cost of the research per student-hour.

Newton: But there is one difficulty that has been puzzling me for fourteen years, and I am not quite. . . .

Superintendent (with snap and vigor): Guess you had better overcome that difficulty by Monday morning or quit.

The sinister side of the president's control of the professor is shown in two cases which have recently become public property. At Wesleyan University the professor of political science and sociology was compelled to resign after some remarks on the observance of the Sabbath and, at Lafayette College, the professor of philosophy and psychology was dismissed because his teaching was thought not to be in accord with the stricter standards of the Presbyterian church. We are not here concerned with questions of academic freedom or of permanence of tenure, but only with the methods of determining what the professor may say and how he shall be dismissed. As a matter of fact, in these two cases the alleged infractions of orthodoxy were slight. Several clergymen have told me that they might very well have made the remarks of the Wesleyan professor, and the Lafayette professor remains a Presbyterian clergyman in good standing. At Wesleyan, the president asked for an explanation of the remarks of the professor, demanded his resignation and accepted it, the three letters being written on the same day without the possibility of official consultation with the faculty or trustees. The fact that in this case the alleged ground for the dismissal was not the real cause does not improve the situation. At Lafayette, in like manner, the president wrote to the professor demanding his resignation in view of the supposed contents of a course. In this instance the professor was given a hearing before the trustees, but the president was naturally upheld.

A distinguished army engineer has recently stated that he would not accept the commissionership of police for New York City unless

the law should be changed so that a policeman might be dismissed without the right of appeal to the courts. It is supposed to be a part of the moral etiquette of the New York police to commit perjury in defense of one another, and it may or may not be that arbitrary power would for a time be desirable. But an army officer has no such control over his subordinates, who can only be court-martialed after definite charges and trial. One result of the difference between the police system and the academic situation is that no one can question the personal courage of the police. Whether it is better to lie like a policeman or to run to cover like a rabbit need not be argued, as it would doubtless be agreed that conditions should be such that this is not the necessary alternative. The slur about the third sex in America is unwarranted, but it would be better if there were not enough smoke to give rise to the alarm of fire.

Professors in the better institutions are not often dismissed because they or their views are not in favor with the administration, though this happens much more frequently than it becomes known, for the professor is naturally disinclined to drag the "pageant of his bleeding heart" across the continent and have his name put on the employer's black list. But it is this publicity which is his safeguard; and we have exercised by the body of professors and the general public a real democratic control, to which the president and trustees must submit. Stanford University has not recovered in thirteen years, and will not recover in another generation, from the loss of prestige due to the dismissal of Professor Ross and its sequelæ. Departments of economics and sociology in leading universities would not recommend a successor to Professor Fischer at Wesleyan, and public spirited men would not accept the position. At Lafayette, the resignation of the president has followed promptly the publication of the report of the American Philosophical and Psychological Associations on the dismissal of Professor Mecklin. On the other hand, Harvard maintained its high position by promptly

offering lectureships to Professor Ross and Professor Fischer.

But while professors are not often dismissed because the president does not like their teaching or their personality, the possibility is present every day with a resulting demoralization not easy to estimate. Even more serious is the fact that the president may be responsible for the appointment and promotion of instructors and professors, and for increases in salary—for salaries are sometimes increased, however remote this contingency may seem to most professors. Semi-secret increases in salary by favor of the president must be regarded as intolerable. It tends to divide those who suffer under it into three classes—courtiers, quietists and rebels. The courtiers are those most likely to flourish in the system to its ultimate collapse.

I have had the privilege of proposing and seeing adopted by the trustees of Columbia University a change in the statutes in the direction of social democracy. We had long had, like some other institutions, provision for a sabbatical leave of absence on half salary. But in practise it proved that the sabbatical year was usually claimed only by those professors who had independent means or no family; it was thus a case of class privilege. Five years ago the statutes were altered to allow the alternative of a half-year leave of absence on full salary. This gives the professor some eight months for travel and research without loss of salary, and the institution sacrifices no more than on the half-salary basis, except in so far as more professors benefit. The plan deserves adoption in other institutions, and may properly be mentioned in a paper concerned with democracy in the university. It also gives opportunity for the frivolous remark that it might be an advantage if the statutes of a university provided for leave of absence of the president so often as he liked on double salary.

We do not know whether the progress of civilization has in the main been due to great men who have directed it, or whether these are essentially by-products and epiphenomena of social and economic forces. It is, therefore,

no wonder if we can not decide categorically whether or not it is well to have in the university one leader whom the rest of us will follow. But it is probably undesirable, as it is certainly undemocratic, to have a boss who drives us. This is the fundamental difficulty in our present university organization. The president is responsible to the trustees who in the private corporations are responsible to no one. The deans and heads of departments are responsible to the president who names them, and their subordinates are responsible to them. This department-store system reverses the correct or, at all events, the democratic direction of responsibility. The department or group should name its head and those to be added to it. The teachers or professors should name their deans and their president who should be responsible to them. The trustees should be trustees, not regents or directors. Their relations should be with representatives of the faculties, not exclusively with a president whom they appoint and who in practise is likely to select them.

It may be that the high-tide of presidential autocracy in our universities is now ebbing. At any rate we are discussing the problem more freely than in the past. I have obtained and published opinions of some three hundred professors who have done scientific work of distinction. These exhibit a very wide-spread dissatisfaction with the existing system. There is naturally much difference of opinion as to the remedies, but five sixths of them favor reforms in the direction of greater faculty control and less presidential autocracy. The remaining one sixth are mostly executive officers or men in institutions where the faculties have more than average influence. Thus the great university now entertaining this conference has maintained the better traditions. It has been said that if the faculties name the professors, there will be inbreeding and deterioration. To this it may be replied that Yale is represented in the National Academy of Sciences by eleven members; Cornell and Pennsylvania, with twice as many students, each by one member.

Harvard, like Yale, has maintained a meas-

ure of faculty and alumni control. President Eliot, whose masterful personality has been influential in exalting the presidential office, has at home deferred more to the corporation and overseers on the one side and the faculty on the other than lesser presidents. The plan adopted at Harvard of promotion after a fixed term of service with uniform increments of salary and permanence of tenure for the full professor removes him from the most humiliating relation to the president. At Cornell the faculties have been granted the right to elect their deans, and President Schurman advocates faculty representation on the board of trustees. At Princeton the departments have been authorized to recommend appointments and promotions, and a committee elected by the faculties meets with a committee of the trustees, this latter plan being in my opinion the most feasible method of improving the academic situation. Other reforms at various institutions in the direction of greater faculty control might be cited, the most striking and recent being the referendum vote of confidence obtained from the faculties by the president of the University of Illinois.

Whoever or whatever may be the occasion of reforms in academic control, the real cause must be the sentiment of the professors, and this can only be developed and expressed by proper organization. I am proud to belong to an association that at two consecutive meetings has taken action exhibiting a group consciousness of this kind. A year ago the American Psychological Association unanimously passed a resolution proposed by me to the effect that it is undesirable for its members to accept work in summer-schools or extension courses in which the pro rata payment is less than their regular salaries. Last Christmas at New Haven the association took the action to which reference has been made on the dismissal of the professor of philosophy and psychology from Lafayette College. An influential committee of one hundred on research has been formed by the American Association for the Advancement of Science. It may be that the time has now come when an association of American university professors might be or-

ganized, similar to the medical and bar associations, which would be an influential force in improving the conditions under which our work is done. It should not be forgotten that the maintenance of high standards in the university is as important for the community as for the professor, and his efforts on its behalf are by no means narrowly selfish. The future of the American university does not depend upon its machinery, but upon its men. The danger of a bad system is that it may gradually demoralize the spirit and ideals of the men working under it, and may keep from it or drive from it the kind of men who are needed.

When a speaker has only twenty minutes in which "to set the crooked straight," he can not be expected to devote much time to explaining that it is not so very crooked and is made of sound timber. The university is the noblest monument which we have inherited from the past and at the same time the most powerful engine driving forward our civilization. We owe to it the tribute of truth and the duty of service. It is our part to make it a democracy of scholars serving the larger democracy to which it belongs.

J. McKEEN CATTELL

CALVIN MILTON WOODWARD

CALVIN MILTON WOODWARD was born in Fitchburg, Mass., on August 25, 1837. He was graduated from Harvard in 1860 with the degree of A.B. and with the honor of membership in Phi Beta Kappa. In 1905 Washington University, and in 1908 the University of Wisconsin, conferred upon him the degree of LL.D.

During 1860-65 he was principal of the Newburyport, Mass., high school. In 1862 he was granted leave of absence for one year. During this period he served first as lieutenant and then as captain of a company in the 48th Massachusetts Volunteers. His regiment helped patrol the Mississippi in Louisiana and was under fire in the siege and storming of Port Hudson.

In 1865 he came to St. Louis, where in the service of Washington University and of his

adopted city and state he passed the last forty-nine years of an active, energetic and fruitful career. At first he was the vice-principal of the academic department. In 1866 he was doing college work and was principal of the O'Fallon Polytechnic Institute. In 1868, under the authority of the university corporation, he began the organization of an engineering department. In 1870 he was made Thayer professor of mathematics and applied mechanics, and dean of the polytechnic faculty. In 1880 the St. Louis Manual Training School was opened, with Dean Woodward, its organizer, as director, and immediately it became the educational novelty of St. Louis, and for that matter, of America.

From this time, with some minor changes, he held until 1896 the positions of Thayer professor of mathematics and applied mechanics, dean of the engineering school and director of the manual training school. He resigned the deanship in 1896, but resumed the duties of that office in 1901 and again from that time carried his threefold official title until his final retirement from active service in the summer of 1910. He had remained in the harness until the close of his seventy-third year, when he retired upon the Carnegie Foundation. "His eye was not dim and" apparently, "his natural force was not abated." Four more happy years came to him in literary work, on educational boards and in the free use of his time and talent in the lecture field. On January 19, just passed, he was actively at work in behalf of a philanthropic enterprise which had deeply interested him for two or three years when the cerebral lesion attacked him which on January 6 proved fatal. After a private funeral service at the house. January 12, there was held at the church of which Dr. Woodward was an active member a memorial service at which Dr. Dodson, his pastor, Mr. Langsdorf, his pupil and colleague, as well as his successor as dean, Mr. W. A. Layman, president of the Wagner Electric Company, and Mr. Ben. Blewett, city superintendent of public instruction, spoke of his services to society, to the university, to mod-

ern scientific and civic progress and to general education.

Through all his busy years he lectured frequently in America on educational and scientific subjects and on special occasions in England. His contributions were numerous to periodicals and to the proceedings of the many learned societies of which he was a member. He was the author of two volumes upon manual training, one published by Heath & Co., the other in London and afterwards by the Scribners. During the years of his retirement he has written and published a notable text-book of more than 500 pages upon rational and applied mechanics. Every page shows the mature teacher and the clear logician reasoning with his students. Though published last year, the work is about to pass to a second edition.

It was fortunate for Mr. Eads, and for the engineering fraternity as a whole, that, from the bold inception to the triumphant completion of the St. Louis bridge, Dr. Woodward, then an enthusiastic young professor in his thirties, watched every operation and knew the great work to the minutest details. He went to the bottom of the piers, where men were working under more than four atmospheres of pressure. He was among the first to walk the plank connecting the approaching ends of the big middle arch. He knew the designs, drawings, contracts and unusual tests of material. With some of his students he was a passenger on one of the fourteen locomotives that tested the structure. When the work was done, which to this day stands in a class by itself, Captain Eads entrusted to Professor Woodward the task of writing the history of the achievement. This record occupied two busy years and remains an enduring monument to its author and to James B. Eads. At the time of its appearance it was said to be the most important contribution to engineering literature that had appeared in America. The book is widely distributed among the scientific libraries of the country; but the original edition is nearly exhausted and another will probably never be printed.

About that time, Professor Woodward, im-

pelled by the serious needs and deficiencies of those of his students who were ambitious to become engineers, conceived and developed the manual-training idea. Upon this phase of his work it is not necessary for us to dwell. The innovation had many and bitter enemies, for it was not then apparent how manual training could help in making educated men. But a large section of the educational world in America now believes in it and has adopted it in many secondary schools as one element in the formation of the efficient citizen.

At a critical time in the development of the University of Missouri Dr. Woodward was a curator and president of the board. His service at that time to higher education in his state will never be forgotten. While the Louisiana Purchase Exposition was in progress at St. Louis, Dr. Woodward was president of the Aeronautical Congress which did much to create a strong faith throughout the country that the conquest of the air was near at hand, and he himself made important contributions towards the solution of the problem.

In 1894 Dr. Woodward was president of the Society for the Promotion of Engineering Education, and in 1909-10 he was president of the North Central Association of Colleges and Secondary Schools, the first time in the history of that useful organization that a college professor not of presidential rank presided over its deliberations.

Dr. Woodward was chosen president of the American Association for the Advancement of Science for the meeting of 1906. That the choice was a happy one no one could deny who was fortunate enough to be present at the opening session in New Orleans. Since the Civil War this was the first visit of the American Association to a southern city. Southern hosts and northern guests vied with each other to make the occasion a delightful one. As usual the first formal session of the meeting was given up to courteous welcomes and responses. The splendid way in which President Woodward rose to the possibilities of graceful speech none of those present will ever forget.

Dr. Woodward served his city conspicuously

in many matters pertaining to its growth and development. At one time the city census was questioned and he was chosen superintendent to repeat and verify it. He was always ready and forcible in the discussion of the engineering problems of the city, and served terms as president of both the St. Louis Engineers Club and of the St. Louis Academy of Science. As a member of the city school board and several times as its president, he has given character and direction to the public school system of St. Louis.

Professor Woodward married Fanny S. Balch, of Newburyport, Mass., in September, 1863. She survives him together with three daughters, two of whom are married. His home life was an ideal one; to enter within its circle was always a privilege.

In hasty review we have selected only a few of the instances where Calvin Milton Woodward has come prominently before the country. The story of a long life of cheerful labor and distinguished service in the college halls can never be told. There is no tangible record of the daily lessons enforced with an unflinching and overflowing spirit of optimism. But it is this work and this spirit that produce a sure and lasting effect upon the lives of students. Just as the gentle sunshine is the most potent force in nature, so the efficient teacher, who on the whole is quite often an object of condescending sympathy in our social state, is nevertheless the mightiest agent in the progress and development of society, for he is developing its coming leaders and, therefore, more than any other agency, is shaping its destiny. Happy is that teacher who knows his power and lives true to his high calling. His name may soon be forgotten, but the essence of his life and labor passes on from heart to heart and from generation to generation.

Such a man was Dr. Woodward. As a teacher he lived. As a teacher he sought his life's reward. A little more than a year ago in a company where were many of his former students he expressed his conviction that no epitaph could more highly honor him than

the simple statement "He was a teacher of men."

C. A. WALDO

WASHINGTON UNIVERSITY,
ST. LOUIS

ROBERT KENNEDY DUNCAN

By the death on February 18 of Dr. Robert Kennedy Duncan, director of the Mellon Institute of Industrial Research of the University of Pittsburgh, American science lost one of its most illustrious devotees. Dr. Duncan was known to the public at large in two important lines of service. First, as an interpreter of science, in which branch he was preeminent; he gave life to the most abstruse things of cold science and made them of intense interest. His books, "The New Knowledge," "The Chemistry of Commerce" and "Some Chemical Problems of To-day," while of the highest scientific accuracy, are so written as to hold the reader's sustained attention to the end. The other line in which he will be remembered is as the originator of the unique system of *the service of science to industry*. Dr. Duncan felt that he was fortunate in being able to live to see this system established on a permanent basis in the Mellon Institute of Industrial Research. With his usual farsightedness he carefully trained those who were to take his place when he was gone and the institute embodying the system he originated will go on as a living monument to its founder.

Certain of the ideas he had in mind in working out a practical method whereby the learning of the university could be brought to the service of industry are interesting, in that they show prominent traits of his character. He once told me that he experienced the keenest pleasure of achievement when he thought of the opportunities he was able to offer to young men through the working of this system. He loved to speak of his laboratory as a center of opportunity for young men. And that fact really indexes the keynote of his character. He was absolutely unselfish. He sought nothing for himself and was continually trying to advance his "boys,"

as he loved to call them. And he was in his relations to them an older brother more than a formal director. Dr. Duncan always felt that in scientific investigation the things of the spirit were more important than material things and that the many seemingly impossible results which had been achieved in his laboratories were accomplished solely because of the fine spirit which he instilled into his men.

Dr. Duncan was born in Brantford, Ontario, 1868. He graduated with first-class honors in chemistry and physics from the University of Toronto in 1892 and did graduate work in Clark and in Columbia universities. He was a preparatory school teacher of chemistry from 1893 to 1901, when he became professor of chemistry at Washington and Jefferson College (1901-6). He studied abroad during the years, 1900-1903, 1904 and 1907. Up until 1906, Professor's Duncan's life as it was evidenced to the outside world was simply that of a successful growing teacher of chemistry. But in his inner life a great purpose had been developing and finally took form in his system of industrial fellowships. He really led a dedicated life—a life dedicated to the working out and founding of a method of sympathetic cooperation between industry and learning, whereby industry, the university, the public and young men would be greatly advantaged. In 1906 Dr. Duncan was called to the University of Kansas as professor of industrial chemistry and it was then and at that time that he initiated on a small scale his new system of industrial fellowships. In 1910 he became director of the department of industrial research of the University of Pittsburgh, which department, in 1913, became the Mellon Institute. It was in the University of Pittsburgh that industrial fellowships expanded with such extraordinary rapidity to the present large institution.

As an educator in the field of science Dr. Duncan's influence was very far reaching. He had the rare faculty of imparting to his students and associates his own overflowing enthusiasm. He inspired a peculiar loyalty to the highest ideals of scientific truth. Nu-

merous short articles from his pen, in addition to his books—written with a unique charm of expression and power of interpretation—gave a widespread interest in things scientific. His investigations and writings on the conditions of the employment of chemists by industrialists had a marked effect in bettering the status of the industrial chemist.

As to the personal influence of his life on those with whom he came in contact, I do not know how better I can express this than by appending the following tribute from one of his "boys."

RAYMOND F. BACON

ROBERT KENNEDY DUNCAN, AS ONE OF HIS BOYS
KNEW HIM

THERE are scattered over this country a fairly large number of men each of whom is glad if Robert Kennedy Duncan ever referred to him as "one of my boys." Yes, there are many of us who are better men, who see the values of this life clearer for having been one of his "boys." To some of us he was a professor of chemistry, to some he was a director of industrial research but to all of us he was a big brother, yes even a father. He was an employer of none of us in the ordinary sense of the term. Robert Kennedy Duncan was truly "a fisher of men," a witness of the light which has ever shone clearly for those who have lived the gospel of man's brotherhood.

I wish I had the pen to enable others to understand something of his leadership. None can see all the facets of a gem from one angle. Nevertheless I shall attempt to speak of him, as one of his "boys" who has been privileged to know him.

I can do no better than to select a few of his own sentences about certain deeds of men which excited his own admiration. He was fond of military analogies. In a recent article on industrial research which appeared in *Harper's Magazine* he likened the modern spirit of discovery in scientific research to the spirit of the young Marco Polo.

Let us contrast synthetic rubber with synthetic indigo. The commercial synthesis of indigo was

accomplished after a Kitchener-like advance, in which each step at a time was buttressed and buttlemented by coordinated facts until the summit was attained and the fortress was won. It was an irresistible march of the horse, foot and artillery of scientific endeavor. The attack upon rubber, on the other hand, recalls nothing so much as the raid of the adventurers accompanying Cortes into the wilds of Mexico. Ludicrously few in number and ill equipped save with a *dauntless spirit*, they plunged desperately into a wilderness absolutely unknown and denized by countless thousands of a malignant and disciplined enemy; yet they conquered Mexico. The conquest of Mexico was incredible, it was *unreasonable* to the military tactician; so is the conquest of rubber incredible to the tactician of scientific research.

Allow me to quote another sentence which I think shows one of the great elements of his leadership.

Of course I have forgotten something. I have forgotten the afternoon tire in the garish light of the laboratories, the hard cot at night by the laboratory table, the broken experiments, and the heart-breaking disappointments to endeavor. But so did Marco Polo, for you will look in vain through all his glowing pages for the bitter cold of the morning camp, or the intolerable heat of the desert or of the pain of insect pests, or of his sorrow at the loss of his goods—all forgotten in the retrospect of his wonderful journey.

Valery-Radot wrote two delightful volumes giving us a picture of Louis Pasteur, yet there are two incidents which to me are most illuminating and recall Doctor Duncan. The author tells us of Pasteur's anguish on the occasion of the death of a boy from rabies. Pasteur forthwith undertook an investigation of the subject. Finally one sees this great, tender-hearted man with all the wonderful vision of his mature years brought near death's door and in one last spasm of effort crying: "We must work. We must work." And so Robert Kennedy Duncan was removed by the accident of death just as his dreams, his great constructive dreams, for the amelioration of man seemed to be in the dawn of their fulfillment. Only last December Doctor Duncan attended the Atlanta meeting of the American Association for the Advancement

of Science and met Dr. Howard A. Kelly. Sixty thousand people dying of cancer in this country every year! He returned from that meeting burning with a desire to do something. The idea that radium is and undoubtedly always will be beyond the reach of thousands of these sufferers, *that* was what appealed to him. Couldn't something be done about it? He believed there could. He told his ideas to a Pittsburgh business man, who very quickly said, "It would give me real pleasure to help you tackle this thing."

Another sentence of Doctor Duncan's will always stick in my mind and I think gives us a clue to his fine spiritual nature. In discussing the synthesis of ammonia from nitrogen and hydrogen he recalls that up to 1908 the best work of Haber, Nernst and others had failed to give results of industrial promise and as Dr. Duncan said of Nernst's work:

With this final investigation, then, it was "thumbs down" for the subject; it was finished, exhausted, dead.

But Professor Haber had a feeling that the thing could be done. Doctor Duncan says:

It is to be understood that this "feeling" which possessed Haber was not the obsession of an ignorant dreamer but was actually the expression of a *faith that lay deeper than reason* on the part of one who knew, possibly better than any one else from the standpoint of reason, its folly.

The splendid qualities which he so admired in others he himself possessed. It has ever been such rare spirits which have done the impossible, have pointed the way.

THE WELLESLEY COLLEGE FIRE

The fire at Wellesley College on March 17, which totally destroyed College Hall, the oldest and largest building, has brought great loss to the college and has greatly disabled four science departments.

College Hall, which originally contained the whole college community, at the time of the fire was a dormitory for two hundred and fifteen students, and also held the offices of the administration, the lecture rooms for the greater part of the college, and the laboratories of the departments of geology, physics.

psychology and zoology. The entire equipment and the collections of each of these four sciences are destroyed, and the department libraries of geology, physics and zoology. As a consequence, these departments are seriously crippled and are in great need of assistance.

The collections of the geology department were very valuable and some were very rare mineral specimens. Recently many new cases had been acquired and space for exhibition. The lantern of this department was the only piece of apparatus that survived the fire, but the thousands of lantern slides were destroyed.

The more important losses to physics are lantern slides, collection of crystals, a unique collection of Nicol prisms, and complete files of the important scientific journals, some dating back to 1800.

Besides the actual equipment, the most serious loss to the psychology department is the destruction of its records of experiments, memory and intelligence tests on normal and abnormal subjects, the results of several years of work.

The zoology museum was far richer than was generally known. It was inadequately housed and crowded, and its specimens were never displayed to advantage. The collections represented the results of many years of labor and of careful selection, and were essentially study collections, planned for special courses, and constantly in use by different groups of students. The losses which will be felt most keenly by the individual courses are the North American birds and insects, the general invertebrate collections, recently enriched by material from the zoological station at Naples, the mounted and disarticulated skeletons, the histology and embryology slides, and the physiology apparatus.

The personal losses of the teaching staff are very great. In the zoology and psychology departments alone, original work, drawings, notes, collections, microscopes and apparatus, books and reprints, all are gone.

Aid has come already in generous measure to the four stricken departments from many colleges and museums near Boston, from Clark University, Mt. Holyoke College, the

University of Pennsylvania, Vassar College, and from former students and friends of Wellesley; and material has been lent and given that will enable the scientific courses to reopen with the rest of the college on April 7, in the laboratories of the departments of astronomy, botany, chemistry and hygiene, all of which are in separate buildings and are therefore untouched by this disaster.

Our future needs are very great, buildings, equipment, material for work, museum specimens, books. May the realization of these needs bring yet more help to our support.

CAROLINE BURLING THOMPSON
WELLESLEY COLLEGE

THE PRESIDENCY OF THE UNIVERSITY
OF IOWA

THE president of the University of Iowa has, under the date of March 20, 1914, addressed to the Iowa State Board of Education, the following letter:

By this letter I submit to you my resignation as president of the State University of Iowa, to take effect at your earliest convenience. Some explanation of this action is due to you and to those interested in the welfare of the university. Such explanation follows:

At the meeting of your board held at Cedar Falls, March 11, you considered in executive session a number of administrative matters concerning the university. Among other things at that time you dismissed a professor of the university without a hearing and without the knowledge or advice of the chief executive of the institution. Whether or not the facts, if you have them, warranted the professor's dismissal is not now the issue to which I call your attention; and I pass over for the moment the obvious fact that the professor himself had a right to be heard. I can not avoid the inference that your action is deliberately intended to express lack of confidence in the administration of the university.

Before I came to the university in 1911 I asked you in writing to consider thoroughly the step you proposed; it was for you to decide whether or not I was the man for the place and I called your attention to this fact. As part of the terms on which I finally accepted the position you agreed in writing that all recommendations for appoint-

ment and for dismissal in the university should come through my office to your board. This is the procedure in any well-governed university. At that time, also, I asked explicitly that if at any time you should feel that you would be more comfortable with another man in my position, you express to me frankly that feeling; and I stated that I would, then, with good will, promptly retire. To this also you agreed.

I can not but regret that when the time came to act under this agreement, you did not do so, frankly and honorably. You had only to ask for my resignation to receive it at once. The course you adopted to accomplish the same object is unworthy of yourselves, unjust to me, and involves a still more serious injustice to another man whose case should have been considered on its merits after proper hearing and investigation, and not entirely subordinated, as I believe it was, to the evident desire to raise, quite needlessly, a personal issue between your board and myself.

It is not my purpose to dwell on this point, however. Interpreting your action as I have no doubt it was intended, and conforming on my own part to the understanding on which I came here, I willingly withdraw from a position which I accepted only at your earnest solicitation and which I have no desire to retain unless I can demand and receive your entire support. I do this with the less regret because as I recall the issues which have arisen between us and which have led to your present attitude, I am as firmly as ever convinced that the ideals and policies which I have held for the university during the past two and one half years have been right and educationally sound; that no single instance of personal politics or self-seeking on my own part has contributed to our differences; and that if you had chosen to give me a reasonable opportunity for working out these ideals and policies they would have justified themselves in ample measure by the results.

If it were possible that I have exaggerated the significance of your action in its relation to myself, my course would still be the same. No man can be held accountable for his responsibility unless his authority is respected, or for his policies unless he is given a free hand to carry them out. This principle is recognized in all well-governed colleges and universities, as it is in every well-organized business. The efficient government of this university on any other basis is impossible, and I could not be a party to so hopeless an experiment even if it were your desire that I should.

SCIENTIFIC NOTES AND NEWS

At the annual meeting of the National Academy of Sciences, to be held in Washington on April 21, 22 and 23, the William Ellery Hale Lectures will be inaugurated by two lectures on "The Constitution of Matter and the Evolution of the Elements," by Sir Ernest Rutherford, of the University of Manchester.

A SPECIAL convocation held at Oxford on March 24 conferred the degree of doctor of science on Surgeon General Gorgas.

THE Fothergill gold medal of the Medical Society of London for 1914 has been awarded to Dr. John George Adami, F.R.S., LL.D., Strathcona professor of pathology and bacteriology at McGill University, for his work on pathology and its application to practical medicine and surgery.

WE learn from *Nature* that the council of the University of Birmingham has appointed Professor Charles Lapworth emeritus professor of geology in recognition of his services during his occupation of the chair of geology. The senate recently signalized his retirement by the presentation of an address and a gift of plate, and on March 11 another presentation was made to him by a large number of his old students.

THE last number of the *Münchener medizinische Wochenschrift* is a special issue in honor of the sixtieth birthday of Professor Ehrlich, which occurred on March 14.

DR. LAWRENCE MARTIN, of the University of Wisconsin, has been elected a corresponding member of the International Committee on Glaciers.

MR. R. J. POCOCK, of Queen's College, Oxford, has been appointed to direct the observatory of the Nizam of Hyderabad.

PROFESSOR F. KEEBLE, F.R.S., professor of botany, University College, Reading, has been appointed director of the Royal Horticultural Society's garden at Wisley.

DR. JOHN W. COLBERT, Albuquerque, has been asked by the Rockefeller Foundation to assume charge of its research work in a campaign to be inaugurated for the eradication

of hookworm disease in Central and South America.

MR. H. GLAUERT, of Trinity College, and Mr. H. Jeffreys, of St. John's College, have been elected to Isaac Newton studentships in the University of Cambridge.

THE Sarah Berliner Research Fellowship has been awarded for the year 1914-15 to Miss Ethel Nicholson Browne, Ph.D. (Columbia), now instructor in biology at Dana Hall, Wellesley, Mass. Miss Browne will spend the year at the University of Würzburg and at the Zoological Station at Naples, doing research work in cytology.

THE Kansas City Section of the American Chemical Society celebrated its one hundredth meeting on March 21. This section was chartered in 1900 and has been holding alternate meetings in Lawrence, Kansas, and in Kansas City, Missouri. At this meeting Dr. Wm. McPherson, of the Ohio State University, was the guest of honor and delivered an address illustrated with lantern slides upon "European Laboratories and Chemists."

FROM May 5 to June 23 a course of eight lectures on the rate of the blood-flow in man in health and disease will be given in the physiological laboratory of London University, by Dr. G. N. Stewart, professor of experimental medicine, Western Reserve University.

It is stated in *Nature* that the Faraday Society arranged a general discussion on optical rotatory power, to be held in the afternoon and evening of Friday, March 27, in the rooms of the Chemical Society, Burlington House, Professor H. E. Armstrong and Professor Percy F. Frankland, presiding. Papers on various aspects of the subject were to be read by Professor Hans Rupe (Basle), Professor H. Grossmann (Berlin), Professor Leo Tschugaeff (St. Petersburg), Dr. Darmon (Paris), Dr. T. M. Lowry, Mr. T. W. Dickson, Mr. H. H. Abram, Dr. R. H. Pickard, Mr. J. Kenyon and Dr. T. S. Patterson.

DR. HARRY BURROWS, lecturer in chemistry in the Sir John Cass Technical Institute, Lon-

don, died on March 15, at the age of forty-two years.

PROFESSOR JOACHIMSTHAL, director of the University Hospital at Berlin for the surgical treatment of cripples, died on February 28, aged fifty-two years.

DR. ADELBERT VON WALDENHOFEN, emeritus professor of applied physics in the Vienna Technological School, has died at the age of eighty-six years.

THE House committee has favorably reported the bill providing that the historic botanic garden, located for many years at the foot of Capitol Hill, be removed to Rock Creek park, in the far northwest section of the city. The bill also provides that the garden is to pass from the direct control of congress to that of the department of agriculture.

MR. JOHN LAMBERT CADWALADER left \$195,000 to public institutions with which he was associated, and gave valuable works of art to the Metropolitan Museum, and books to the New York Public Library. The public institutions which received legacies are the New York Public Library, \$100,000; the Metropolitan Museum of Art and Princeton University, \$25,000 each; Harvard University Law School and the New York Zoological Society, \$20,000 each, and the Alumni Association of the Harvard Law School, \$5,000.

A MATHEMATICS CLUB is in process of organization at the Ohio State University. Professors and students will have an equal share in discussing mathematical literature and some of the newer developments in the science. At the first meeting of the club, Professor R. D. Bohannon, head of the department of mathematics, will speak on the spirit of the old mathematics as related to the new, showing the quality of research, and of critical investigation which has taken the place of former unthinking respect for authority.

THROUGH the generosity of M. Spendiaroff of St. Petersburg, the International Geological Congress presents at each session a prize amounting to about 450 roubles for the best

work in some specified field of geology. The next prize will be awarded at the session in Belgium in 1917 for the best work in petrography giving new light on the general problems of the science. Two copies, at least, of any work presented for the competition must be sent to the general secretary of the last congress, R. W. Brock, deputy minister of mines, Ottawa, Canada, at least one year before the next session.

THE Christiania correspondent of the London *Times* states that according to interviews in the Norwegian papers, it looks doubtful whether Captain Amundsen's expedition can start in 1914. The *Fram* appears to be delayed and must be at San Francisco at latest at the beginning of July. If delayed Captain Amundsen will use the time in order to practise his aviators and scientific staff. The *Fram* will take three aeroplanes. The German Antarctic explorer Captain Filchner has been engaged to act as observer and photographer. Dr. Nansen will next summer undertake an oceanographic expedition with the Azores as a central point.

A JOINT meeting of the Association of American Geographers and the American Geographical Society is being held on Friday and Saturday, April 3 and 4. The program is as follows:

THE EVENING LECTURE (ENGINEER'S HALL)

L. A. Bauer: "The General Magnetic Survey of the Earth."

FRIDAY MORNING SESSION (AMERICAN GEOGRAPHICAL SOCIETY'S BUILDING)

W. H. Hobbs: "Land Sculpturing in Arid Lands with Observations from Northeastern Africa."

FRIDAY AFTERNOON SESSION (AMERICAN GEOGRAPHICAL SOCIETY'S BUILDING)

T. Wayland Vaughan: "The Platforms of Barrier Coral Reefs."

D. W. Johnson: "Botanical Phenomena and the Problem of Coastal Subsidence."

E. W. Shaw: "Characteristics of the Mississippi Delta in the Light of Comparative Studies of Some Old-World Deltas."

Oliver L. Fassig: "The Period of Safe Plant Growth in Maryland and Delaware."

SATURDAY MORNING SESSION (AMERICAN GEOGRAPHICAL BUILDING)

Frederick J. Turner: "Geographic Influences in American Political History."

J. Russell Smith: "The Tree as a Factor in Man's Adjustment to Hilly and Rocky Land."

W. W. Atwood: "Over the San Juan Mountains to the Ancient Cliff Dwellings of the Mesa Verde."

Collier Cobb: "The Forest of Sunburst: A Study in Anthro-geography."

SPRUCE, abundant in the New England and Lake States and in Canada, has heretofore been the standard wood for making news print paper and as long as there was a supply sufficient to meet the needs of the paper industry there was no reason to seek substitutes. But heavy inroads have been made on the spruce forests of the western part of the United States in this day of great circulations and large editions, especially of Sunday papers with their many parts. On a rough estimate, a newspaper with an average circulation of sixty thousand copies and an average edition of twenty pages, uses each day the product of about four acres of forest. When this figure is multiplied by the great number of newspapers published in the United States, many of them with much larger editions, and when this is further multiplied by 365, because many papers are issued every day of the year, it can be seen that the drain upon the forests is enormous. Foresters say that even under the most approved methods known to their profession, it could scarcely be expected that spruce would be able to hold its own, but would need supplementing by other material. It is but natural, therefore, that paper manufacturers are looking for new sources of supply which will furnish an abundance of wood pulp, at a price which will not be prohibitive. Poplar and a few other woods are used, but they do not go very far. In the national forests there are many woods considered inferior by lumbermen. Yet they are available for purchase at low rates and many of the timber stands are readily accessible. The forest service, in its desire to utilize to the best advantage all of the resources of the federal timber holdings,

has been seeking proper uses for these trees and has experimented in making pulp from them at its pulp laboratory at Wausau, Wisconsin, an auxiliary of the forest products laboratory at Madison. The Wausau laboratory is equipped with standard machinery and all experiments are carried out under conditions which duplicate commercial practise. As a final test of the value of some of these new woods under practical conditions, arrangements were made between the forest service and the *Herald* to print some part of its edition on paper made from various woods that showed promise as substitutes for spruce. These woods were ground at the Wausau laboratory; the product was then mixed with the usual proportion of chemical pulp and made into news print paper, rolls of which were sent to New York for the experimental run.

SETTLERS in western Kansas are cutting and marketing soap weed, or Spanish bayonet, to supply the demands of soap manufacturers, according to a report recently received from officers of the Kansas national forest. There are various plants in the southwest locally known as soap weed, called amole by the Mexicans, but the one gathered by the Kansas farmers, technically known as *Yucca bacata*, a species with exceptionally large fruits, is the most used. The soap manufacturers, however, utilize the tops or the roots. Manufacturers are paying \$8 a ton for the plant at the railway stations, while the estimated cost of cutting, drying, baling and hauling ranges from \$5 to \$6, depending upon the distance to the railroad. Since a man can ordinarily get out a ton a day, the gathering of the soap weed affords an opportunity to secure a fair day's wages at a time when other ranch activities are not pressing. After cutting, the soap weed is allowed to dry from 60 to 90 days and then is baled up in the ordinary broom-corn baling machine. For a long time this weed has been made into a soapy decoction which the Indian and Mexican women have used, particularly for washing their hair, for which purpose it is considered especially suited, since it contains no alkali. Present-day soap manufacturers use it for toilet and wool soaps. Its qualities have been known for a long time, but the har-

vesting of soap weed is just now becoming commercially important. The industry is now operating on lands adjacent to the Kansas national forest and it is expected that the demand will soon spread to that forest, some portions of which bear an abundant supply of the plant. There is a plentiful supply of it throughout southern Colorado, Arizona, New Mexico and Texas. Forest officers have considered this weed a nuisance, since it is the nature of the plant to spread over extensive areas and kill off other vegetation. It is particularly a pest on stock ranges. In line with its policy of range improvement, the government is anxious to rid the forage areas of all such injurious plants, and it is the hope of the forest officers that the commercial demand for soap weed will soon reach such proportions that it will not only take an otherwise useless product, but also will eradicate it from areas which could be utilized to better advantage for the supplying of forage to cattle and sheep.

It is generally recognized that boric acid in considerable quantities is an original constituent in the waters and gases given off with volcanic emanations. In fact, the Tuscan fumaroles, in Italy, have been an important commercial source of boric acid for a long time, and in the past, possibly even to the present time, almost all the boric acid brought into the European market has been derived from this source. There is abundant evidence of the presence of boric acid in volcanic emanations in many parts of the world. On the other hand, boron is so rare a constituent of rock-forming minerals that it forms an almost inappreciable small percentage of the earth's rock mass as a whole. A short study of the borate deposits in Ventura County, Cal., supplemented by more cursory examinations of similar deposits in the vicinity of Death Valley, has been made by Hoyt S. Gale, of the United States Geological Survey, and a new theory of the origin of the deposits of colemanite, or borate of lime, in these regions has been advanced by Mr. Gale in Professional Paper 85, Part A, recently published by the Survey. While this theory has not yet been entirely proved, there is much in its favor and it affords suggestions and a working basis

for further observation. The supposition of a desiccated saline lake to explain the origin of the colemanite has little to support it beyond rather general assumptions. The character of the deposits themselves indicates rather a vein type of formation. Other salines which would naturally be expected in desiccation deposits resulting from natural saline solutions are not found in association with the colemanite. Those who have supported the desiccation theory have offered no explanation of the cause which might produce colemanite in such massive deposits as a product of water evaporation, while, on the contrary, its formation from limestone in veins by replacement of carbonic acid with boric acid is a natural hypothesis that deserves further investigation. The relations of the deposits to basalt lava flows indicate the probable origin of the boric acid at the time of the extrusion of these lavas, although it may be assumed that this acid continued to find its way into solution of the circulating ground waters long after the period of the extrusions.

UNIVERSITY AND EDUCATIONAL NEWS

PROVISIONS for the creation of a trust fund said to be approximately \$500,000 for the maintenance of male graduates of the Williamsport, Pa., high school at Cornell University are made by the will of Albert Dubois Hermance.

MR. EDGAR PALMER, a Princeton graduate of the class of 1903, has offered to build and present to Princeton University a stadium costing \$300,000. Mr. Palmer is a son of the late Stephen S. Palmer, who was for many years a trustee of Princeton University and gave large sums to the university, including the Palmer Physical Laboratory.

THROUGH the cooperation of the estate of the late Dr. C. Annette Buckel, of Oakland, a research fellowship for the study of feeble-minded children has been established at Stanford University. The department of education, under the direction of its head, Professor E. P. Cubberly, will have the appointment of the fellow, who will work in cooperation with Professor Lewis M. Terman. Dr. Buckel was

an Oakland physician known for her charitable work in Oakland and for her interest in feeble-minded, backward and delinquent children. On her death her estate was left in trust to Miss Charlotte S. Playter, of Piedmont, to be used to advance the condition of backward and feeble-minded children. Miss Playter has turned the money over to Stanford. The income amounts to about \$500 a year, and the board of trustees of the university have added an additional \$500 to the fellowship.

WORK has begun on a temporary recitation and administration building for Wellesley College. It will be a wooden structure, one story high, of the simplest possible construction. It is contracted to be finished by May 1. Classes will begin on April 7, the regular date for the opening of the spring term. There are no plans as yet to replace the geological, physical, psychological and zoological laboratories which were destroyed by the burning of College Hall.

THE recent disastrous fire at Wellesley College wiped out the entire equipment of the department of physics. This department, organized in 1878, was one of the first in the country to offer laboratory practise for undergraduates and possessed much apparatus of value. Within the last few years extensive additions had rendered the equipment thoroughly modern and up to date. The library of nearly three thousand volumes contained complete files of most of the leading periodicals, English, French and German, including the *Annalen der Physik*, the *Philosophical Magazine*, and the *Philosophical Transactions* since 1800. The loss is total.

YALE UNIVERSITY and the University of California will exchange professors next year. Professor John Wurts, of the Yale Law School, will lecture at California, and Professor G. H. Boke, of the School of Jurisprudence at California, will lecture at Yale.

DR. THOMAS H. MACBRIDE, professor of botany, has been appointed acting president of the State University of Iowa.

DR. NATHANIEL E. LOOMIS, assistant professor of chemistry at Bowdoin College, has

accepted a professorship of physical chemistry at Purdue University.

Dr. L. D. BRISTOL, now of Syracuse Medical School, has been appointed to succeed Dr. G. F. Ruediger as director of the public health laboratory of the University of North Dakota. Dr. R. T. Young has been appointed professor of zoology and succeeds Dean M. A. Brannon as director of the University Biological station at Devil's Lake.

Dr. PRAFULLA CHANDRA RÂY has been appointed to the Sir Taraknath Palit professorship of chemistry, and Mr. C. V. Raman to the Sir Taraknath Palit professorship of physics in the Presidency College, Calcutta.

DISCUSSION AND CORRESPONDENCE

DADOURIAN'S ANALYTICAL MECHANICS AND THE PRINCIPLES OF DYNAMICS

PROFESSOR E. W. RETTGER's review of my "Analytical Mechanics," which appeared in number 995 issue of SCIENCE, gives a wrong impression of my treatment of the principles of dynamics.

The reviewer's criticisms are directed, mainly, against my claim of having based the science of mechanics upon a single dynamical principle. Starting from certain premises, which can not stand close examination, Professor Rettger arrives at the conclusion

He makes more assumptions than are usually made in elementary text-books of mechanics.

Let us consider the main points of his criticisms in detail and see whether the foregoing statement is based upon facts.

On page 16, he introduces the conception of "force" as an "action" and without hesitation applies vector addition to a system of forces. What is he doing here, but assuming the "parallelogram of forces" in its most general form?

It is intimated here that the "parallelogram of forces" is a dynamical law which I have "assumed" without formally introducing it as a new law. It is a fact that I have applied vector addition to forces "without hesitation," but I have shown as little hesitation in treating velocities, accelerations, torques, linear momenta and angular momenta as

vectors. Why did not Professor Rettger accuse me of having assumed the "parallelograms" of these magnitudes? Is the "parallelogram of forces" more of a dynamical law than the "parallelogram" of torques, for instance? The "parallelogram" law applies to any vector and is not at all a characteristic of forces, therefore it is not a dynamical law. It does not even deserve being called a "law" when applied to a special type of vectors. In its most general form the "parallelogram law" is the principle of the independence of mutually perpendicular directions in space, a purely geometrical principle. A special case of it is known to students of plane trigonometry as the "law of cosines." In the first chapter of my book this principle is given in its most general form as well as in its several special forms, and is applied to vector magnitudes of different types. After devoting an entire chapter to vector addition and after defining force as a vector, to introduce the "parallelogram of forces" as a new law, as Professor Rettger would have it, could serve only to show that the man who did it could not have a clear conception of the meanings of the terms he was using.

On page 102 he assumes that a force is proportional to the acceleration produced. This assumes Newton's second law.

This statement is not quite right. The relation between force and acceleration, which I have called *force-equation*, is derived on page 106 from the fundamental principle which I have postulated. In this derivation I have made use of the definition of *kinetic reaction*, which is stated and illustrated on pages 102 to 105, but this is not equivalent to "assuming" a new principle. Will Professor Rettger claim that to define the terms used in a principle is equivalent to introducing or "assuming" new principles? Suppose I had based my work upon the principles of the conservation of energy and of the conservation of momentum should I have no right to classify and define the different forms of energy and of momentum without being rightly accused of having introduced new principles? Will Professor Rettger consider the definitions of momentum, of potential energy, and of kinetic

energy as principles and state that mechanics can not be based upon the principles of the conservation of energy and of momentum alone?

What about the law itself? The first part of the law is clear. "To every action there is an equal and opposite reaction" is nothing but Newton's third law of motion. The word "or" leads us to think that the second part means the same thing as the first part.

Had Professor Rettger examined my book with greater care he would have noticed that I have used the term "reaction" in a slightly different sense and that with this difference the "first part" is not at all Newton's third law but has the same meaning as the "second part," and that the two "parts" are only two different forms of the statics principle. Further he would have seen that the first form is not made use of, the entire work being based upon the second form alone, and would not have charged me of having assumed Newton's third law in addition to the one I have introduced. The first form is left out entirely in the papers which I published on the subject.¹ In one of these papers I have even shown that Newton's third law is a direct consequence of the second form.

I have postulated the following principle, which I have called the *action-principle*:

The sum of all the actions to which a body or a part of a body is subject at any instant vanishes:

$$\Sigma A = 0.$$

Then I have classified and defined the different forms of action. On this principle I have based my treatment of mechanics, and claim that I have given it a degree of unity and logical continuity which is not common to treatments of elementary mechanics. This is made possible by the simplicity and flexibility of the action-principle, which is easily grasped by the beginner, yet conveys a depth

¹ "On a Progressive Development of the Principles of Mechanics," *Physical Review*, May, 1913; "On a Progressive Development of Mechanics Based Upon a New Form of the Fundamental Principle of the Science," *American Journal of Science*, February, 1914.

of meaning and breadth of application commensurate with the knowledge and ability of the student.

Besides this pedagogical advantage my treatment involves a point of view which is in harmony with our present ideas of dynamical phenomena, as it is shown in my recent paper on the subject.²

H. M. DADOURIAN

YALE UNIVERSITY

A NEW METHOD OF COOPERATION AMONG UNIVERSITIES

In April, 1910, was formed at Kansas City, Missouri, the Missouri Valley Conference of Heads and Governing Boards of Universities. The Conference embraced, however, only the institutions up to that time belonging to the Missouri Valley Conference for athletic purposes. There have been many conferences and associations of professors of universities and presidents of universities, or both, and there have been conferences of school boards representing the public schools in various cities, but this is probably the first attempt on the part of university governing boards to accomplish a general understanding and co-operation in regard to matters affecting institutions similarly situated. The conference arose over the matter of intercollegiate football, the question so fruitful of controversy and discussion. The reason for the conference was as follows: There had been introduced into the board of regents of the University of Kansas a resolution abolishing intercollegiate football. The vote was a tie and the motion was lost. The question was brought up again and after thorough discussion it was agreed by the board of regents of the University of Kansas that it was unwise to attempt to settle that question in one university alone and that all of the universities of the then existing Missouri Valley Conference, through their heads and governing boards, should be asked to meet in a general conference at Kansas City in April, 1910. It was at the time of large and pointed discussion and criticism of intercollegiate football and after the matter had been clearly laid before the institutions most interested all of them accepted the invi-

² *Loc. cit.*

tation and all sent delegates except the University of Iowa. The institutions represented were the University of Missouri, the University of Nebraska, Washington University, Drake University, the Iowa State College, and the University of Kansas. Of these the universities of Nebraska, Missouri and Kansas were represented by members of the board of regents or curators and the presidents of the institutions. Drake University was represented by its president, Iowa State College of Agriculture and Washington University by professors sent by the governing boards of the institutions to represent them. The meeting resulted in a general conference upon athletics as affecting institutions in the Missouri Valley and rules were passed by the Conference and afterwards reenacted by the individual boards of regents, largely affecting the status of intercollegiate football. Among these was the rule abolishing the game on Thanksgiving Day, abolishing the short-term professional coach, and requiring that all college games be played on college grounds.

The second conference was held at Des Moines, January 6, 1911, at which various questions left over from the Kansas City meeting were discussed and acted upon. At that conference the University of Iowa was also represented by its president and board of regents. Washington University was not represented. The discussion at this conference widened out to include other things than athletics. A general discussion of the fraternity question was ordered for the next meeting and committees on uniform financial accounting and uniform pedagogical accounting were authorized. It was plain from the discussions at the second conference, and indeed by formal action, that it was intended to make the conference a permanent one to take into consideration any question touching the common life of universities that might need consideration and uniform action.

The third meeting of the Conference was held in Lincoln, Nebraska, January 19, 1914. The University of Iowa had in the meantime withdrawn from the Missouri Valley Conference and the State Agricultural College of

Kansas had been added. All of the institutions in the Conference were represented. Most of the attention of this conference was given up to matters other than athletic and it was more evident than before that the Conference was developing into a general conference on the welfare of the universities having so much in common. The fraternity question received much attention, as did the question of competency in teaching. It is probable that in succeeding meetings such questions as the following may be taken up and discussed, if not formally acted upon: the ethics to be observed in calling teachers from one institution to another; substantially uniform salaries for the same grade of instructors; cooperation in giving advanced and little called for courses; interchange of students and instructors; cost of education. It seems possible, therefore, that this Conference is a beginning of a new type of cooperation, having especial significance and authority because of the fact that the Conference is made up of presidents and governing boards where the primary power lies.

FRANK STRONG,
Chancellor

UNIVERSITY OF KANSAS

SCIENTIFIC BOOKS

From the Letter Files of S. W. Johnson.

Edited by his daughter, ELIZABETH H. OSBORNE. Yale University Press. 1913. Pp. 292.

A notable feature of the applications of science to the arts and industries which characterized the second half of the nineteenth century was the phenomenal evolution of agencies for scientific investigation in the interest of agriculture and the rise of a system of public research institutions extending over every country of the civilized world. The life story of the subject of this biography is essentially the story of the birth of this system in the United States and its growth from a few modest analytical laboratories to an imposing group of national and state institutions actively engaged in agricultural research, in the teaching of agricultural science,

and in the dissemination of the results of investigation.

The career of Samuel W. Johnson presents few dramatic features. He lived the quiet, simple life of the student, occupying a professorial chair in a single university for forty years, yet few, if any, have exerted a more profound influence for the promotion of scientific agriculture. A man of genius as well as of thorough training, he early conceived the idea of making the conquests of science serviceable to the basal industry of the country. Even in his student days, in 1851, he published an article—"County Agricultural Institutes"—setting forth his earliest conceptions of the ideas which later assumed a more definite form. Five years later, in an address before the New York State Agricultural Society on the subject "The Relations which exist between Science and Agriculture" he said:

"I have full faith not only that science *may* accomplish much for agriculture in the way I have indicated, but that she *will* be speedily put about the work. The tendencies of our time prophesy this. The notion that there is anything essentially antagonistic between science and practise is daily meeting its refutation, both in the laboratory and in the field. I may confidently ask, where better than in our own country shall this idea find realization? Our country now has the strength of the oldest nations with all the freshness of youth. She is girding herself up to contest among the nations for the prize of science. What worthier triumph for our republic than to win for her millions the boon of a rational agriculture?"

But Professor Johnson had not only the genius to conceive this ideal and the faith to follow it throughout a long and fruitful career, but the tact and persistence necessary to bring about its institutional embodiment.

His first opportunity presented itself in connection with the introduction of commercial fertilizers into the United States. In March, 1853, he published, under the title "Superphosphate of Lime," an account of the results of analyses which he had made of

two samples of artificial fertilizers offered for sale. This work was probably the first of its kind in this country and was the prototype of a vast amount of similar work during the next twenty-five years, done at first as a private undertaking and later as chemist of the Connecticut State Agricultural Society and of the Connecticut State Board of Agriculture. "It was characteristic of the man first to form and tenaciously hold the broad idea, based upon a universal and permanent need; and then, realizing an opportunity for practical work, to set about using his skill and knowledge in routine analysis performed with all possible accuracy in order that these simple analyses should be so absolutely right that they might be an unassailable foundation for the wider work to come after."

In 1853 he was appointed first assistant and in 1856, professor of analytical chemistry in the Yale Scientific School—later the Sheffield Scientific School—and with various titles remained an active member of its faculty until 1896. During all these years, with the capacity and equipment to take high rank among scientific investigators, he devoted his powers chiefly to the instruction of his students, to the preparation of those classic text-books, "How Crops Grow" and "How Crops Feed," and to the service of the farmers of his state in promoting the popular understanding of the aid which science could render to agriculture. His platform was the farmers' meeting, his means of publication chiefly the official report and the agricultural newspaper; while the humble and prosaic work of fertilizer analysis served to furnish the practical demonstration.

Not for almost a quarter of a century did he see the concrete result of his labors in the establishment in Connecticut of the first agricultural experiment station in the United States, at first as a semi-private institution and two years later as an independent state institution under his directorship. This was followed by the founding of similar stations in other states in rapid succession, culminating ten years later in the passage of the "Hatch

Act," providing national support for at least one such station in every state. At the time of his death, in 1909, there were fifty-six of these stations in the United States with an average annual income almost eleven times that of the Connecticut station at its foundation, to say nothing of the enormously increased research activities of the United States Department of Agriculture. Truly the little seed planted in 1853 had become a tree.

In the organization and development of these new institutions the standards established by Professor Johnson and the experience gained at the Connecticut station were material factors in bringing about the success which was so soon attained. At the outset, the American stations were of necessity largely occupied with the analysis and valuation of fertilizers. From the very start, however, original research formed a part of the program of the Connecticut station, while the increase of the state appropriation in 1882 and the assignment to the station in 1887 of part of the Hatch Fund, enabled investigation to be extended to wider fields. Throughout, the work of this station, both under Professor Johnson's administration and that of his successor, has been characterized by the same sane method, the same absence of sensationalism and the same confidence in the power of good works which characterized the fertilizer analyses of the early fifties.

In 1896, Professor Johnson became professor emeritus, and in 1900 resigned the office of director of the experiment station, occupying for a year longer the position of advising chemist which was created for him. He passed peacefully away July 21, 1909, having retained to the last his keen interest in the progress of science and in the problems presented in the development of modern chemistry.

Such was, in barest outline, the active life of an unusually gifted man who had a high conception of the obligations of the scientist to the public. No brief review can do justice to the delightful personality of the man as those knew it who were closely associated with

him, and which pervades the book like an aroma, revealing itself especially in the judiciously chosen extracts from his correspondence which constitute the major portion of the volume. His biographer has done her work, not only with filial piety but with notable discrimination and restraint and with marked literary ability. In these days of intense emphasis upon the practical, no more inspiring or elevating volume can be recommended to the student of agriculture who is looking forward to a career as teacher or investigator than this record of a life which attained success in the best sense through the unselfish consecration to the public service of the rigid training and high ideals of the genuine man of science.

H. P. ARMSBY

STATE COLLEGE, PA.

Researches on Irritability of Plants. By J. C. BOSE. London and New York, Longmans, Green and Co. 1913. Cloth, 15 x 23 cm. Pages xxiv + 376; 190 illustrations, largely graphs. Price \$2.50.

Physiologists who are familiar with the earlier electrophysiological researches of Bose will be interested in his recent volume on certain kinds of plant responses, which recounts the results of an application of his very ingenious methods to new kinds of problems. Research workers will find this book replete with novel ideas and novel ways of attaining quantitatively comparable measures of plant irritability. The author is not primarily dealing with the fundamental problems of protoplasmic phenomena; his work may be said to concern itself, rather, with the physics of the plant as a whole, or with that of its organs, than with the component cell happenings to which recent physiological inquiry seeks to reduce these aggregates. It is somewhat remarkable that animal physiology, on the one hand, has attained a high state of development along the lines here dealt with (with its studies of the superficial phenomena of muscle contraction, blood pressure, the electrophysiology of muscle and nerve, etc.), and that the findings of this sort of study form a very

considerable basis for the more fundamental researches that prevail at the present time, while plant physiology, on the other hand, has come to the study of cell phenomena largely without passing through this stage. Electrophysiology plays but a very subordinate rôle in plant physiological texts, and refined quantitative studies of the grosser movements of the plant have never had great vogue. It is in just this general field that Bose's writings lie, and his results, while not calculated now to arouse great interest *per se*, must be taken into serious account and will doubtless throw valuable indirect light upon the more fundamental lines of study now mainly attracting attention.

The author makes, at the very beginning of the book before us, a suggestion which has great possibilities in physiological research. "Is there any means by which we might find out whether a given influence has contributed to the plant's well-being or the reverse, whether it has left it more or less excitable," etc.? "The relation between the stimulus and the response would thus form a gauge of the physiological condition of the organism" (pages 1 and 2). In physiological terms, the *tone* of the organism as a whole is here in question, and the quantitative relations between stimuli and response are to be drawn upon as measurements of tone. Now, it is just this matter of the physiological condition of organisms for the estimation of which we most require objective methods; it has been the practise of students of plant physiology to define their organisms in the terms of the older descriptive work, assuming, for example, that a number of given plants are the same thing physiologically because they exhibit the same superficial shapes, sizes, etc., to the taxonomist. Two workers may employ the same species or variety in the taxonomic sense, but their organisms may be very different physiologically and they may disagree entirely on the sort of response attained with a given stimulus or set of environmental conditions. If some of the dimensions or characteristics of the internal condition of the organism used in an experiment could be

measured and stated, much would be done to avoid many of the wasteful arguments which so often diminish the efficiency of physiological workers. From Bose's suggestion it appears to the reviewer that the methods of the present work may be of value in the physiological definition of our plant subjects, just as similar methods in animal physiology are proving of value to medical diagnosticians.

The subject-matter of this book defies useful treatment in a review. A few statements may, nevertheless, be made here. Most of the study has to do with the familiar paratonic movement of the leaf of *Mimosa*, though other organs receive attention at particular points. To obtain an automatic graph ("phytogram" or "plant script") of this response, a thread is attached to the petiole and to a light bent lever above, the latter counterbalanced and carrying a writing point which moves over a smoked surface. A glass plate, allowed to fall by clock work, furnishes the receptive part of the apparatus. To avoid too great friction it was found necessary to make the recording point vibrate in a plane at right angles to the receiving plate, and it was possible to arrange the vibrations so as to mark time. Thus a record with this "resonant recorder" appears as a line indicated only by a series of dots on the smoked surface, the distances between the dots indicating small units of time. The apparatus is so ingenious and delicately efficient as to excite wonder and admiration in and for itself. Stimuli of several kinds are employed, applied to the leaf in various ways. The most frequently used are thermal (obtained electrically, so as to be quantitatively controlled) and electric. The graphs show a short latent period, a period elapsing between beginning and end of the fall of the leaf ("apex time") and a long recovery period. Besides these three time periods is of course to be considered the amplitude of the movement, in characterizing the nature and intensity of the response.

Some of the topics experimentally dealt with are the following—the terms themselves show the parallelism between the plant phenomena here described and the familiar ones

called by the same names in animal physiology: additive effects; influence of load, temperature and intensity of stimulus; fatigue; staircase response (quite like that of muscle); tetanization; death spasm (it looks as though a means were here offered for determining when death of a tissue ensues); influence of gases on excitability; effect of intensity of stimulus, of fatigue and of temperature on latent period; effect of various conditions on velocity of transmitted impulse; positive and negative galvanometric and turgidity responses (each stimulus gives rise to both, but the weaker positive—erectile—response is quickly followed and masked by the stronger negative—“contractile”—one); polar effects, etc. Polar effects are very thoroughly investigated. “With feeble current the kathode excites at make and not at break. The anode excites at neither make nor break,” etc. The variation of polar reaction under tissue modification, as with age, etc., is studied, with important results. In the later chapters of the book *Biophytum* and *Desmodium gyrans* are employed in studying multiple and automatic (autonomic) responses. The pulsations of *Desmodium* leaves are thoroughly investigated.

The first two sentences of the last paragraph of Bose's book sum up the general outcome of his studies as well as can be thus briefly done: “In surveying the response of living tissues we find that there is hardly any phenomenon of irritability observed in the animal which is not also found in the plant. The various manifestations of irritability in the plant have been shown to be identical with those in the animal.”

JOHNS HOPKINS UNIVERSITY

SOCIETIES AND ACADEMIES

ANNUAL CONVENTION OF THE UTAH ACADEMY OF SCIENCES

THE seventh annual convention of the Utah Academy of Sciences was held at Salt Lake City, December 26 and 27, 1913, in the chemistry lecture room of the University of Utah.

In all, three sessions were held—the first be-

ginning at 8 o'clock Friday evening, the second at 9:30 o'clock Saturday morning, and the closing session at 2 o'clock Saturday afternoon.

From the standpoint of business transacted, this convention of the academy will rank as one of the most important in its history. A committee was appointed to take steps toward the publication of a bi-monthly magazine under the auspices of the academy. Another committee was appointed to look after the entertainment of distinguished scientists who may be visiting in Salt Lake City, and to assist them should they desire to investigate features of the region of scientific interest in their especial lines.

Professor C. W. Porter, of the Utah Agricultural College, was elected to fellowship. Miss Florence Knox, Professor Christian D. Steiner, Professor Jakob Bolin, Professor Franklin O. Smith, Dr. Helen I. Mattill, all of the University of Utah; Dr. Fred W. Taylor and Mrs. Amelia R. Taylor, of Provo; Willard R. Harwood and N. W. Cummings, of Salt Lake City; Professor George R. Hill, Utah Agricultural College, Logan, and H. R. Hagan, Logan, were elected to membership.

The constitution was amended to provide for a permanent secretary-treasurer.

The following are the officers for the ensuing year:

President—Professor Marcus E. Jones, Salt Lake City.

First Vice-president—Dr. Harvey Fletcher, B. Y. U., Provo.

Second Vice-president—Dr. C. N. Jensen, B. Y. C., Logan.

Permanent Secretary-treasurer—A. O. Garrett, High School, Salt Lake City.

Councillors-at-large—Dr. A. A. Knowlton, U. U., Salt Lake City; Dr. Joseph Peterson, U. U., Salt Lake City, and Dr. F. L. West, U. A. C., Logan.

The following papers were read at the annual convention:

“The Question of Valency in Gaseous Ionization,” by Dr. Harvey Fletcher, B. Y. U., Provo.

“Community Life among Insects” (the presidential address), by Dr. E. G. Titus, U. A. C., Logan.

“Some Metabolic Effects of Bathing in Great Salt Lake,” by Dr. Helen I. and Dr. H. A. Mattill, U. U., Salt Lake City.

“Corn under Irrigation,” by Dr. F. S. Harris, U. A. C., Logan.

“Practical Experiments with Root-borers,” by

Professor M. Rich Porter, Weber Stake Academy, Ogden.

"Workable Phosphates of the Mississippian," by Professor William Peterson, U. A. C., Logan.

"How Far is Scientific Extension Practicable?" by Dr. E. G. Peterson, U. A. C., Logan.

"Some Features of the Recent International Congress of Geologists," by W. D. Neal, Salt Lake City.

"Outline of Mining and Smelting Conditions at Santa Fe, N. M.," by B. A. Berryman, San Pedro, N. M.

"The First Law of Irrigation Practise," by Dr. John A. Widtsoe, U. A. C. (Read by title.)

"Uranium and Vanadium Deposits in Utah," by Professor Marcus E. Jones, Salt Lake City.

A. O. GARRETT,
Secretary

NEW ORLEANS ACADEMY OF SCIENCE

THE regular monthly meeting of the Academy was held in the Richardson Memorial Building, Tulane University, on Tuesday, February 17, with Dr. Isadore Dyer, president, in the chair and a large number of fellows and members present. The president appointed a committee of two to draw up suitable resolutions upon the death of Dr. Alcee Fortier, who had been a fellow of the Academy for thirty years and for some time corresponding secretary. The first paper of the evening was read by Dr. Irving Hardesty, professor of anatomy, Tulane University.

A number of objections to the Helmholtz theory of hearing were cited and attention was called to the impossibility, anatomically, of the basilar membrane serving in the manner usually assumed for it. Then the tectorial membrane was shown to be coextensively with the organ of Corti, to occupy the logical position, extending with one edge free over the peripheral surface of the neuro-epithelium and nearer the scala vestibuli, and that it is far more adapted and capable of being the chief vibratory structure in hearing, its flexibility being much greater and its proportions varying far more than those of the basilar membrane. A telephone theory of hearing was applied to the tectorial membrane and a model was shown in which the three divisions of the auditory organ were represented and in which the tectorial membrane was simulated as nearly as possible, both as to position and varying proportions. Sounds of varying vibration frequently applied to this model

indicated (1) that the tectorial membrane does vibrate; (2) that sounds of low vibration frequency throw the entire membrane into vibration; (3) that sounds of high frequency throw only varying extents of the more slender, basal end of the membrane into vibration, such sound waves being so damped out before reaching the apical end of the cochlea as to be incapable of producing vibrations in the thicker, apical end of the membrane; (4) a certain small amount of resonance seems apparent in the tectorial membrane, but probably little more than is possessed by the diaphragm of the telephone.

The second paper was by Dr. R. B. Bean, also of the department of anatomy, Tulane University, on "The Cartilaginous Tip (Woolner-Darwin) and the Skin Tip of the Human Ear." The speaker explained that "Darwin's tubercle" in the adult represents the cartilaginous tip of the ear of the fetus, which turns forward during the late stages of fetal life. There is at the same time a folding over of the skin and a shrinking with the folding, which leaves lines in the skin over the upper outer part of the helix. These lines are present on all ears that have been observed so far. They converge ventrally, thus indicating where the skin tip has turned under the ventral edge of the helix. The lines are not always over "Darwin's tubercle" but are frequently superior to this cartilaginous point, which seems to indicate that the skin or cartilage has shifted in development. By means of these lines one is able to demonstrate that certain distorted ears, which look as if they had been injured by accident, are in reality normal. The majority of the ears of about 150 negroes preserved in formalin at Tulane University seem to be distorted, and until these lines were discovered they were considered abnormal, frost-bitten, scarred, or otherwise mutilated, but they appear to be normal because the lines of the skin are present in their proper position and relations. Observations upon thousands of negroes show that this condition of apparent distortion of the ear is characteristic of that people. The ear of the Negro may, therefore, be called a distorted or mutilated looking ear. It is smaller than the ear of the white people, and shows a greater extent of retrograde metamorphosis.

There was considerable discussion of both papers in which Dr. Mann, Dr. Clo, Dr. Dyer and others participated. The academy then adjourned.

G-R Laboratory Rheostats

Types and Sizes

G-R Laboratory Rheostats are made in five types and thirty-six different sizes, with numerous current capacities and resistances in each size.

Uses

These rheostats have been found useful for the following purposes:

Switchboard Work Meter Testing
Work in Standards Laboratories
General Laboratory Work
Wireless Work

In the latter case, windings are non-inductive and free from capacity.

Some of the Users

The list of users of G-R Rheostats includes Universities, Colleges, Technical Schools, Industrial Companies, Makers of Electrical Instruments, and Departments of the U. S. Government (including the Bureau of Standards).

¶ The writers are expert *teachers* of physics rather than experts in *physics*, experimental and theoretical. In this, the physics has not suffered while the attractiveness and effectiveness in class use has been much increased.

¶ *Simplicity of presentation* is a leading feature. The methods of attack, illustrations and examples employed appeal to the pupil.

¶ The *pupil*, his *experience*, *interests* and *needs* have been kept in mind by the authors who have a long experience in teaching the principles of physics.

¶ While the numerical problems give sufficient drill and mastery of the mathematical side of physics, special attention has been given to *avoid* abstruse and complicated *mathematical puzzles*.

¶ The problems emphasize *physical principles* and not mathematical training.

¶ The large number of practical exercises and problems permit testing at many points and of a choice of problems by teachers.

¶ The text comprises over seventy sections, each containing material enough for one recitation.

¶ A feature of the book is "*Important Topics*" which individualizes the essentials.

¶ Another feature is the "*Exercises*" which not only illustrate, but fix in the mind of the pupil the application of physics to home experiences and occurrences in daily life.

¶ The book has a distinct appeal to a distinct class, and shows a proper perspective and pedagogical attitude on the part of the authors.

¶ It is *up-to-date* in all respects.

RECENT BOOKS

Animal Communities in Temperate America.

By **VICTOR E. SHELFORD**, Instructor in Zoölogy in the University of Chicago.

This volume by Dr. Shelford presents the principles of field ecology, illustrated by the more widely distributed animal habitats of the eastern half of temperate North America, and the aquatic habitats of a much larger territory. Six chapters deal with general principles.

In several chapters the animal communities of lakes, streams, swamps, forests, prairies, and various soils and topographic situations are considered from the point of view of modern dynamic ecology. A very valuable feature of the book is the three hundred figures of widely distributed animals chosen to represent the chief types of animal communities and their characteristic modes of life.

380 pages, 8vo, cloth; price \$3.00 (weight 44 oz.).

Artificial Parthenogenesis and Fertilization.

By **JACQUES LOEB**, Member of the Rockefeller Institute for Medical Research.

This new work presents the first complete treatment of the subject of artificial parthenogenesis in English. Professor Loeb published four years ago a book in German under the title *Die chemische Entwicklungserregung des tierischen Eies*. Mr. W. O. R. King, of the University of Leeds, England, translated the book into English, and the translation has been revised, enlarged, and brought up to date by Professor Loeb. It gives, as the author says in the preface, an account of the various methods by which unfertilized eggs can be caused to develop by physico-chemical means, and the conclusions which can be drawn from them concerning the mechanism by which the spermatozoon induces development. Since the problem of fertilization is intimately connected with so many different problems of physiology and pathology, the bearing of the facts recorded and discussed in the book goes beyond the special problem indicated by the title.

[318 pages, 12mo, cloth; price \$2.50 (weight 36 oz.).]

WHAT IS INDUSTRIAL SCIENCE?¹

INDUSTRIAL education is now the most pressing of all educational problems. It is, moreover, a wholly new problem; since the schools have never seriously tried, until very recently, to grapple with it. Up to the beginning of this twentieth century, the working hypothesis of the schools has been that the best possible education for every boy and every girl was that portion of a college education which each was able to secure. The banner of education bore the inscription: "Keep the path open for every child from the kindergarten to the university." The intention of this motto was good, in that it was supposed to express the idea of equal opportunity for all; but it was interpreted by schoolmen to mean that the college course was infallibly the best possible course for everybody; and that, therefore, the elementary schools and the high schools were doing their work most efficiently if those who survived their ordeal could successfully get by the guards at the gates of the colleges.

The rapid development of educational insight in the past decade has shown the fallacy of assuming that the same opportunity for all was synonymous with equal opportunity for all. The desire to discover what equal opportunity for all might mean has led to much careful study of the individual differences and of the individual needs of pupils, and also to some careful analyses of the foundations of school philosophy. These studies have shown school-

¹ Presented at the meeting of the Central Association of Science and Mathematics Teachers at Des Moines, November 29, 1913.

men that, turn and twist as they may, they are always face to face with three mighty facts. These are: (1) That the present age is an age of machines, with a new set of ideals of its own; (2) That the schools are still too much under the influence of the ideals of a grammatical, machineless age which is now rapidly passing away; and (3) That not only industry, but also the public at large, is demanding a new type of schools whose graduates shall feel at home in and be able to cope successfully with this modern world of machines.

Now facts are facts, whether we like them or not; and it is a hopeful sign of growth that schoolmen are no longer trying to obscure these three great facts by devout longings for the will-o'-the-wisp of culture for its own sake. We schoolmen have reached the point where we are seriously trying to harmonize these relatively new facts with the rest of our knowledge. Such, at least, is my attitude in trying to define what, in the presence of these facts, science might do to help the schools to usher in a new era of real industrial education.

That we are all trying to find out what industrial science may mean is proof that we are all pretty well agreed that the work now done under the name of science in most schools can not fairly be called industrial science. Whether that work may justly be called science or not is another question, and one about which there have been and still are perfectly honest differences of opinion. But this is not the topic under discussion. The problem before us is: What is industrial science? and I assume that all are ready to agree that few, if any, have yet defined it in action; *i. e.*, that few, if any, of the present school courses in science can be classed under that head. For the sake of definiteness, this problem will first be discussed for the spe-

cial case of physics. The conclusions reached are equally valid for the other sciences.

Current courses in physics do not meet the demand for industrial physics because the leading ideas on which most of the elementary work in physics is based are fundamentally different from those required by industrial physics. Current courses in elementary physics have been planned by students of advanced physics under the spell of a very one-sided appreciation of what the essential elements of physics are. For when a student undertakes to grapple with such works as Newton's "*Principia*," or Maxwell's "*Electricity and Magnetism*," he finds it no easy task merely to follow the argument and to reproduce the results. Hence he naturally acquires a great admiration for the intellectual genius of the men who created such works. He knows, moreover, that his academic success depends on his ability to reproduce these works as intellectual feats only. When he himself becomes a teacher of elementary physics, he very naturally falls into the habit of presenting physics as a series of intellectual feats—of facts and demonstrations and theories and nothing more. Hence current courses have been framed and many text-books have been written with the sole purpose of teaching the laws and principles of elementary physics as coldly intellectual propositions.

As teachers of elementary physics we have thus been filled with a zeal to impart to others the principles that have cost us so much labor. We have tried to get beginners—mere infants in physics—to repeat Newton's laws of motion with some show of intelligence as to their meaning; we have had them figure coefficients of restitution, although none of us ever met one in real life. We have even let them speculate about atomic magnets and ether and

the kinetic theory of matter, long before they have enough facts at their disposal to make these theories comprehensible. This was natural enough—did not the great artists who created the science of physics do these things? But, somehow, it did not work. It was all too unusual and too abstract and too remote from the interests of real boys and girls. It was too coldly intellectual to satisfy the demands of a world of action and emotion. It was too much like learning and trying to apply the fixed rules of grammar to be really exciting. We therefore had to give it up and try again.

In the second attempt we shifted our enthusiasm from the works of men like Galileo, Faraday and Helmholtz, to the achievements of men like Watt, Stevenson and Wilbur Wright. In other words, we seemed to be giving up trying to make scientific artists out of all of our pupils, and shifted the emphasis over to an ambition for engineers. Not that we forsook entirely the traditions of the past—far from it. We merely tried to use the inventions and achievements of engineers as a bait with which to catch the unwary on the laws and principles aforesaid. We tried to use a boy's natural enthusiasm for steam engines as a means of painlessly inoculating him with the errors of thermometers, the laws of boiling, the laws of fusion, the laws of saturated vapors, and the mechanical equivalent of heat.

This second attempt was a great advance over the first, in that it showed some recognition of the rights of the victims—it took some account of the desires and emotions of the pupils. But even this plan has not succeeded. It is at best a sorry practise to try to make any subject-matter interesting after it has been selected on grounds other than the interests of those who are to learn it. This practise has not and will not satisfy the demands of industry or teach

boys and girls to cope successfully with a world of machines. If it had and would, we would not now be still seeking the meaning of industrial physics.

From the first of these experiences we have learned that an age of machines is not satisfied with a physics teaching that makes a few men competent to reproduce statements of the laws of physics as coldly intellectual propositions at college entrance examinations. From the second we are discovering that the public does not consider that it is getting its money's worth out of a physics teaching that turns out a moderate number of boys and girls with a moderate amount of information about engines, trolleys, telephones and wireless, and some painful memories of a few laws and principles as an added ornament.

Both of these attempts at teaching elementary physics in an age of machines have failed for the same reason; namely, because it is not possible to gain an understanding of this age merely by counting cogs and levers, or by measuring moments and coefficients, or by speculating about atoms and ether. We have in it all overlooked the fact that the works of the great artist creators of the science of physics and those of the great engineers of physics are not intellectual or material products plain and simple, but are the expressions of a mighty spirit worked out through keen intellects into tangible form. The great physicists are great not because they merely have more brilliant intellects than most people. There are relatively many brilliant intellects and relatively few great scientists. The great engineers too have not been great merely because they possessed great intellects. Both the great physicists and the great engineers have been great because they were inspired with the spirit of science. Keen intellects are, of course, necessary too, but they are not the

determining factor. The power in such men has been, is, and always will be found in the spirit with which they work—in their disinterested devotion to their tasks and their sublime faith in the harmony of nature and in the possibility of achieving what they have undertaken.

This is no new or startling theory. It is a very venerable fact. Yet somehow it seems to have escaped attention entirely in the organization of elementary physics courses. Since the spirit of science is the dominant factor in making a great scientist, we physics teachers have not been quite bright in thus omitting it from our courses. We have been trying to play Hamlet, but have inadvertently omitted Hamlet altogether. It is encouraging to note, however, that the importance of this omission has just begun to attract attention. Some progressive teachers include the biographies of physicists in their courses, and some progressive authors include the portraits of great physicists in their texts. If the materials of physics can not be presented in such a way as to arouse a real live scientific spirit inside a boy, it may be well to show him pictures and to tell him stories of men who had it.

Yet, after all, we physics teachers are not so very much to blame for omitting the scientific spirit from our courses. If we had been inspired with it when we were children, all would have been different. When we were young, nobody knew what it was. Great scientists just felt it and lived it, but nobody seemed to think of trying to describe it, or to define it, or to tell how it felt all welling up inside and overflowing in laws and principles. There have been many attempts from Aristotle down to the present time to define the scientific method of thinking. But it is only very recently that the effort has been seriously made to portray in words just how the

scientific spirit feels when it is once safely lodged inside a man.

Now that we are beginning to know something about how it feels to have the scientific spirit inside one, the stone which the builders of elementary physics courses rejected is to become the headstone of the corner of the new industrial physics. For, though they may not know it yet, the thing that the industries need most just now is this self-same scientific spirit. The public is demanding it, employers are seeking it, trades unions are hunting it everywhere, even in socialism, and the world at large in this machine age is crying out piteously for it. If we are ever to have an industrial teaching of science, it will be of a sort that succeeds in developing the scientific spirit inside people. It will be a kind of teaching that does not emphasize the loading of the intellect with facts, principles and theories; but rather one that sees to it that at all costs the hearts of the pupils are filled with the scientific spirit. Hence if we would go forward with the development of industrial physics, we must first recognize what is the essential thing in the scientific spirit.

The essence of the scientific spirit is not, as has been generally supposed, a method of thinking. It is not the intellectual process that has been divided into the steps called observation, induction, hypothesis, verification. This process, if it signifies anything real, is at best but one of the modes in which the presence of the scientific spirit inside is made manifest. Many of us have consciously tried, and as consciously failed, to impose this order of thought on our pupils with the idea that we were thereby serving science. We have failed because the essence of the spirit we want is not of this sort.

The essence of the scientific spirit is an emotional state, an attitude toward life and

nature, a great instinctive and intuitive faith. It is because scientists believe in their hearts that the world is a harmonious and well-coordinated organism, and that it is possible for them to find harmony and coordination, if only they work hard enough and honestly enough and patiently enough, that they achieve their truly great results. It is this faith inside them that inspires them to toil on year after year on one problem. How else could Darwin have toiled on all those years to find coordination in one direction? Was it because he wanted to make himself unpopular with the theologians and to set their tongues to wagging against him all over Christendom? Or was it because the problem interested him, and because he knew in his heart that there must be such a thing as law and order among living organisms, and that such order could be found if only he worked patiently enough and honestly enough?

The same is true of inventors and engineers. Their greatness does not depend primarily upon the fact that they have keen intellects and use scientific methods of thinking. When Wm. McAdoo conceived the idea of the Hudson River tunnels, it was not the idea alone that made him achieve them. Many others had thought of tunnels under rivers before. It was rather his belief that the thing was worth while, backed by an indomitable faith in things and in men. He knew in his soul that the people needed this and that it could be done, and he knew it with such energy that he succeeded in accomplishing it. Brains were useful and even necessary too; but the real source of his success was the will to do, and this in turn comes from a profound and indomitable faith that there is law and order in the world and that therefore it can be done.

Look where you will at physics in real life, and you will always find that the heart

and soul of it is an unquestioned faith in things and in the harmony and relatedness of things, united with an unquestioned faith that it is possible for any man to find harmony and relatedness among things if he devotes himself whole-heartedly to the task.

Look where you will at physics-teaching in the schools, and what do you find? Hundreds of teachers—all of us—bustling around with definitions of the unit in physics bound over our eyes. Open any one of these definitions, and what do we find? That the teachers must see to it that each pupil does not less than 30 experiments described in the following list; that teachers should use algebra and geometry when they find it convenient; that teachers should not confuse the pupils with too elaborate apparatus nor allow them to obscure their results under unintelligible units. Hereunto is appended a mighty syllabus, which has cost some committee many hours of hard labor, and which contains the united wisdom of the committee as to what must be included in the course. Such a syllabus of topics we all carry with us always lest we forget some weighty or massive point, and so leave a vacant space in the logical system with which we are trying to adorn our pupils.

So long as we teachers insist on keeping such definitions and such syllabi before our eyes, so long will a real industrial physics be impossible. The syllabus of industrial physics contains only one topic, and that is a topic that no teacher or committee of teachers has ever yet thought of putting in any syllabus yet made. This may seem strange to us at present, with our eyes all blindfolded in our present stately game of blind-man's bluff; but twenty years from now, when our eyes have been opened and industrial physics is in full swing everywhere, the tables will be

turned. We will then wonder how we ever could have been such silly boys as to have been blinded by syllabi that utterly fail to mention the one and only thing that gives science its final and distinctive claim to a leading place in any system of truly democratic education.

The syllabus of industrial physics will be brief and full of meaning. It will read somewhat like this: Topics I-XC, Paragraphs A-Z. *THE SCIENTIFIC SPIRIT.* This includes: (1) a militant faith in things, in the harmony of things, and in what men can do with things; (2) an eagerness to seek facts and to treat facts as facts; (3) an imagination that is able to see old facts in new perspectives.

This syllabus contains no topics like those in which the current syllabi abound, because there are plenty of books in which all these topics are fully treated. If a man has the scientific spirit, he will look them up in books whenever he needs any of them so that they come to have meaning for him in the joyous work of living. This is no more than he now has to do if he wants really to use those now covered in physics courses in any important undertaking.

This syllabus contains no required list of experiments; because, to a man with the scientific spirit, all life is one magnificent series of experiments.

This syllabus, finally, contains no petty directions to the teacher; because the result demanded is emotional in nature and depends on the tact, the intuition and the scientific spirit of the teacher. Fortunately no one has yet attempted to formulate set rules for the development and administration of the scientific spirit, so there is hope for success here by a real live teacher.

Like all truly great things, this syllabus is beautiful because of its simplicity. It is, moreover, the same for all the sciences. Committees will not have to waste much

valuable talent haggling over its details, but can spend the time thus liberated in learning to apply it. Hence, when it has once been adopted, progress in industrial science will be rapid.

There are a number of reasons why it is certain that this simple syllabus is the one that industrial science is going to adopt. In the first place, this is the syllabus that the colleges now want to have adopted. It is the syllabus that the universities use in their advanced work, and the one that the colleges would like to adopt for their own use if only the secondary schools would be good enough to forget the old syllabi that the colleges made. Although the colleges really want to have this new syllabus adopted, none have yet had the bravery to say so openly; because the new syllabus demands a result which can not be examined in two hours by the college entrance examination board. Even the colleges that lie outside the influence of this board, and that admit wholly on certificate, still like to hold on to the possibility of giving entrance examinations if they ever should want to do so. Standards of something-or-other seem somehow to be maintained by this process.

In the second place, the elementary schools are demanding the adoption of this syllabus of industrial physics. In fact, the elementary schools are seriously trying, with their nature study and their general science, to put it into effect themselves. They know that most children come to the first grade with marked symptoms of scientific spirit cropping out all over them, and they know that these same children leave the eighth grade with their scientific spirit a sad caricature of its original self. But the elementary school can not both make its own teachers and teach the children. The teachers must come from above; and hence progress will be slow until the

high schools, the normal schools and the colleges take hold and help too. That it is decidedly to their own selfish interest to do this is perfectly obvious. If the scientific spirit of the children could be preserved instead of deadened in the schools, the work of the higher institutions would change utterly—would become veritably inspired.

But finally, and most important, the syllabus for industrial science is the one just outlined because it is the one that commerce and industry and the public and the world at large are demanding of the science teachers. This is evident because the history of the development of our civilization shows that, since the destruction of Rome, progress has consisted in a continual series of triumphs by men who believed in things over men who believed in words. Magellan believed in things; and when his fleet had sailed off the west end of the world and sailed safely back on to the east end of it without being seriously inconvenienced by the feat, the words of those who liked to prattle about flat worlds became rather insipid. Watt, and Stevenson and Fulton believed in things so vigorously that they actually succeeded in reducing this earth to about one-eighth of its former size, and in expanding the strength of men to the n th power. No amount of talking could ever have accomplished that. The telegraph, the telephone and wireless have compressed the world to still smaller dimensions. The Hanseatic League, the craft guilds, the so-called Renaissance, the development of a merchant marine, the expansion of industry and commerce, are all the work of men who had faith in things. The effects of this work are not material only; for the tangible results of it have been silently working on men's ideals all the time and as silently reconstructing them. It has done more to make men comprehend the idea of univer-

sal brotherhood than all the words that were ever uttered about it.

All this is work of the scientific spirit as here defined. It is forcing on us new conceptions of goodness and justice, new ideals of success and failure. It is even developing in us a new faith; for the scientific faith in things and in the possibility of finding among things a harmony which includes them all is now expanding into a faith in men and in the possibility of finding among men a justice which includes them all. This fact appears explicitly in the work of Taylor and others on scientific management, and implicitly in the change that is rapidly coming over business methods everywhere.

The prophets of our time are telling us that a few years ago the general idea underlying business and industrial transactions was "get all you can out of everybody and give as little as you can in return." Business is business was the motto. While this idea still pervades much business, the most successful firms at present are those which have felt the inspiration of this expanded spirit of science and which therefore realize that this idea is, in the light of the facts, a false one. To be permanently successful in business or industry, one must deal with the same people for long periods of time; and this is possible only when all parties to the transaction are satisfied. All parties will be satisfied only when there is mutual confidence in one another and a recognition that all have been treated fairly and justly. This means that business and industry are coming more and more to be guided by men who have a faith in men as well as in things, and who believe that there must be a social and economic order which will give a justice that is best for all and which can be found if men seek it long enough and honestly enough. Business men are coming to this faith, not be-

cause it is a pious moral thing to do, but because it produces tangible results. If workmen feel that they have been treated justly, they are happy and take interest in their work; and happy and interested workmen are more efficient than unhappy and rebellious ones. It pays to treat men justly and to seek a justice that is best for all. The scientific spirit always pays when intelligently applied.

Now it is because the people sense the fact that this expanded and more mature scientific spirit is coming to the front in business and in industry, and because they see that it pays, that the public is demanding the development of scientific spirit in the schools. The situation is full of meaning for teachers of science. In the first place, it is evident that the public has come to believe in the scientific spirit. The public has tasted of this spirit and is bound to have more. If the present schools will not supply it, the public will either make it themselves in business, or found other schools that can make it. Are not the business men of Illinois even now trying to have a second set of schools established in the hope of securing just this? Present schools are beginning to have competition in this development of scientific spirit. Syllabi of facts are no longer the sacred symbols of the faith—it is spreading of itself wherever men are honestly trying to cooperate in work that is significant to them. If we science teachers do not wake up to this situation, our jobs will soon be gone, and the schools may be reduced to the function of teaching the three R's.

Besides, we science teachers are really rather dull when we allow our individualities to be submerged by syllabi and definitions of units. Why do we insist on hiding our light under a bushel of facts and principles of elementary science, all of which can be bought for a dollar and a

quarter from any one of a dozen enterprising publishers? And why do we all suppress our personal enthusiasms and all try to make ourselves up to look each as much like the other as possible, and all as much as possible like forty experiments from the following list? That we do so is the more surprising when we realize that we are thereby not merely faithless to our trust as guardians of the scientific spirit, but that we are in addition actually making for ourselves a whole lot of tedious and unnecessary work. It is a great deal easier to develop scientific spirit in lively youngsters than it is to suppress their liveliness with an inherently barren and uninteresting syllabus. It is vastly more fun for the teacher too, if he will just be himself and let his enthusiasm spread through the class. He will not have to be a slave to examination papers and notebooks if he can get the class to working on problems that are really significant and worth while in their eyes. When he sees a class so absorbed in the things they are doing that they forget when it is time to go to the foot-ball game, he can be perfectly sure that they have acquired the scientific spirit and hence need no further examinations. They will then have mastered the syllabus of industrial science.

That we are rapidly drifting toward such work is shown by the success of those experiments in which boys spend half their time in school and the other half in some shop. The shop lends reality to the school work and makes it seem worth while. But the schools might make their work seem worth while without the shop, if only they would adopt the syllabus of industrial science in place of the syllabi that have been standardized by the authority of official utterance of the committee of ten. Those syllabi belong to the age that trusted in words; the syllabus of industrial science

belongs to the age of machines, which is founded on a faith in men and in things.

If I were to stop here, I would have defined industrial physics in its fullest sense. I would not, however, have given any specific directions as to how to go to work to frame a real course in industrial physics. What subject-matter shall be used? What topics? These are very practical and very pressing questions in the every-day routine of schools. To such questions as these there is but one answer; namely, use any subject matter in which you can get your pupils so absorbed that they forget everything else but the thing they are doing. Use the subject-matter of the old syllabus, if you want to, and if you think that you have the genius so to clothe it with significance that all the students will become absorbed in it. It is not absolutely impossible to do this. Experience seems to indicate, however, that teachers will have more success if they change the type of problem from the kind in which only physicists are naturally interested to a kind that has more local color and that the rest of the world find essential. For example, instead of trying to interest the pupils in the errors of thermometer scales, the specific heat of aluminum, or the coefficients of expansion of iron and brass, why not set the class on the problem of finding the best grade of coal in town? Or perhaps they would find the relative efficiencies of various types of cooking utensils and gas stoves a fruitful topic? If such topics as these seem to lack the appeal to the creative instincts, the design and construction of an electric lighting system for a house or a miniature town might prove more stimulating. If this still seems to lack the vitality of the real thing, organize the class into a scientific information bureau and invite the citizens to send in their real problems to the class for solution. A plan of this kind, in operation in

Springfield, Mass., was described in the November number of *School Science and Mathematics*. It suggests rich possibilities.

The best example of industrial science that I know of is the work of the corn clubs and the canning clubs of the south. This work was started and is being guided by the General Education Board, and is wholly independent of all school systems. It has, therefore, not been standardized to death. Corn clubs are for the boys, and their purpose is to see which boy can raise the greatest number of bushels of corn per acre. The boy who, by his careful attention to this work, actually produced 210 bushels from his acre, as well as all the other boys involved, incidentally have been raising other things than corn. They are beginning to have faith in things and in what they can do with things. They are beginning to appreciate the value of facts as facts. Their imaginations are at work, figuring, perhaps, how they may slip the corn belt down south and leave Illinois, with its measly 34 bushels per acre up in the cold. They are contributing to the world's work. They are having real industrial science.

In like manner, the canning clubs are for the girls. They meet at the houses of the members and can tomatoes which they have themselves raised. They work with enthusiasm, and have so far perfected their product that, in open market, they get two cents a can more for it than is paid for factory brands. Unlike factory hands, they are happy in their work. They are learning that the scientific spirit pays. Like the boys, the girls have been raising other things as well as tomatoes. They too are beginning to master the syllabus of industrial science, and to have faith in things and in facts, and to see the world in a new perspective. If this sort of work continues and develops farther, who knows but that

the north, with its highly standardized school system, may have to import its scientific spirit from the corn and canning clubs of the south? If we science teachers wish to avert such a humiliating catastrophe, there is but one thing to do; go to work and develop an equally efficient industrial science in the schools.

This is the only thing that will satisfy the present demand of the public and convert the schools of a machineless age into educational institutions that will turn out pupils competent to understand and to cope with this age of machines. For machines are one of the products of science; and if they have caused misery and slavery among workmen and have reduced human beings to machines, it is because they have been owned and manipulated by men who did not possess the scientific spirit. Machines are bound to master and to control men who try to manage them with words or with the ideals of the past machineless age. Only men with the true scientific spirit are able to understand the real meaning of machines and to use their power for the uplift of humanity. Only men with the sacred faith can ever hope to master and to control them permanently.

C. R. MANN

THE UNIVERSITY OF CHICAGO

THE FUNCTIONS OF AN ENVIRONMENT¹

In its nature the present paper falls within the field of abstract physical science, and it can, I fear, interest biologists only through its conclusions. But there is reason to believe that by means of these conclusions a trustworthy foundation for the systematic study of the environment may be established.

The result of my recent inquiry into the relation between the organism and the environment² has been, as I believe, proof that a

hitherto unrecognized order exists among the properties of the elements. This new order is, so to speak, hidden, when one considers the properties of matter abstractly and statically. It becomes evident only when time is taken into consideration. It has a dynamical significance, and relates to evolution.³ It is associated with the periodic system of the elements in somewhat the same way that the functional order is related to the structural order in biology. Hence it is not independent of the other order, but may be said to lie masked within it.

This is no novel experience, that the consideration of phenomena in time should lead to new points of view. In truth, it might almost have been said *a priori* that a new order must be revealed by a study of the properties of matter in relation to evolution.

This order may be described abstractly as follows:—The properties of matter are not evenly distributed among the elements, nor in such a manner as can be explained by the laws of chance, nor are they altogether distributed in the manner which the periodic system describes. If the extremes be considered, all the physical and chemical properties are distributed with the very greatest unevenness, so that the extremes are concentrated upon a few elements, notably hydrogen, oxygen and carbon. As a result of this fact there arise certain characteristics of the cosmic process which could not otherwise occur.

The characteristics which make up this unique ensemble include the greater number of characteristics and especially the most important and the most conspicuous physical and chemical properties. This order has for cosmic and organic evolution extremely important results—maximal stability of physico-chemical conditions and maximal complexity in the physico-chemical make-up of the surface of a planet; further, the possibility of maximal complexity, durability and activity of physico-chemical systems in such an environment.

All the considerations upon which these results are based are purely physico-chemical,

¹ Read before the American Society of Naturalists, December 31, 1913.

² "The Fitness of the Environment: An Inquiry into the Biological Significance of the

Properties of Matter," New York, The Macmillan Company, 1913.

³ I do not, of course, refer to radioactivity, and the possible evolution of the elements.

and are quite independent of biology in any respect whatsoever. Biology is nevertheless dependent upon them, for life can manifest itself only in active physico-chemical systems. Thus a further and more interesting conclusion arises:—In fundamental characteristics, viz., in the physical and chemical properties of water and carbonic acid and in various other similar respects, the actual environment is the fittest possible abode of life.

To some of my critics this statement not unnaturally seems extravagant.⁴ But I hope that this may be due to my failure clearly to explain its meaning and its foundation, rather than to a real fallacy in its development. For in the first place it is to be observed that by fundamental characteristics I mean just those abstract physico-chemical properties like temperature, concentration, stability, chemical activity, etc., which can be measured. And in the second place, I mean not merely a few of such characteristics, but, so far as physical science can recognize them, all such characteristics. Now there can be no doubt that, in respect to these things, water, carbonic acid and the three elements are really unique, and nobody who has examined the evidence has thus far expressed a doubt of it. I need hardly add that I am speaking of the world as we know it and not of any hypothetical world in which matter assumes unknown forms and activities.

The difficulty, then, must lie in what appears to certain biologists, though I think not to the physicists, as an unwarranted assumption. This is that stability, wealth and variety of supply of matter and energy, and mobility thereof, and a host of other similar characteristics, must be an advantage to life in its effort to evolve, and that this is true not merely of life as we know it, but of any possible life manifesting itself in the world as we know it, in this world of our modern astronomy, physics and chemistry. Further, that the greater the magnitude of these characteristics the greater the advantage to life, and hence

that, among the compounds and elements which we know, the environment made of water and carbonic acid on a planet's surface is the fittest. Of course I do not mean this planet—this earth—but any planet constituted like those of our universe; for I am dealing abstractly, not specifically, with cosmic evolution.

This difficulty raises the question, which evidently can be but imperfectly answered, what are, speaking generally and abstractly, the relations between any material system and the rest of the world? This, once more, is a purely physico-chemical problem.

As a result of the thermodynamical studies of Willard Gibbs and his development of the phase rule, a large part of modern physical chemistry is concerned with the classification of systems, their activities, and the conditions of equilibrium within them. An aggregate of matter occupying a position of space is a physico-chemical system. In physical chemistry it is customary, for the sake of the simplification, to study closed systems, that is to say, systems which are not exchanging matter or energy with the outside world. But it is quite possible to proceed from these closed systems to such as are exchanging matter and energy with their environment. Now the phase rule has made possible a very complete and exhaustive classification and description of systems in a perfectly abstract way.⁵ Necessarily, therefore, it has provided a complete qualitative physical and chemical analysis of the fundamental characteristics of any system.

In addition to its material and spatial characteristics a system must manifest activity. In the very simplest case it will at least exhibit that motion which we call heat. But activity also has been brought completely under the sway of physical science, for energetics deals exhaustively with all forms of physical and chemical activity.

⁵ It must be pointed out that there is a certain incompleteness, which happily is of minor importance for our present purpose, in the failure to take account of such a thing as electrical potential.

⁴R. S. Lillie, *SCIENCE*, N. S., XXXVIII., 337, September 5, 1913; J. Arthur Thomson, *Hibbert Journal*, p. 220, October, 1913.

It seems to be true (one may note in passing) that with the progress of science the term mechanism has come to mean merely any active system. In what follows I shall, therefore, use the word mechanism in this sense. According to this definition the mechanistic explanation of a phenomenon is simply its explanation as the activity of a system, and this is the only explanation known to physical science.

Finally, in addition to its material, spatial, and energetic characteristics a system must also be characterized as a whole and in its parts, in its form, structure, and activity by durability. The consideration as well of time as of activity permits the transition from the statical to the dynamical.

In short, form and size, physical and chemical constitution, activity and duration are the general factors to be considered in any phenomenon whatsoever. In the complete description of any mechanism all must be considered, but, for the purposes of physical science no others need be, or indeed can be, introduced.

It is accordingly possible, without any examination of the results of biology, and even in complete ignorance thereof, to investigate the fitness of the special properties of matter for any mechanism, *i. e.*, for mechanism in general.

THE SYSTEM

The fundamental characteristics of a system are the components, the phases, the concentrations, and further temperature and pressure. Hence fitness for *any* system involves the possibility of the greatest number and variety of components and phases, of the widest ranges of concentrations, temperatures and pressures. It has been shown in "The Fitness of the Environment" that the number of possible components (chemical compounds) consisting of carbon, hydrogen and oxygen is far greater than in the case of other elements; that the meteorological cycle mobilizes on land and sea far greater numbers of other elements than would be the case if water were not the active agent in the process; that an aqueous solution is capable of holding a far greater number of components in far greater

concentrations than can any other; that water makes possible, through its unique thermal properties and its unique qualifications in relation to colloids, the greatest possible number and variety of phases. Moreover, many other similar facts have been established without coming upon an unfavorable instance or exception in the course of prolonged search. As for wide ranges of temperature and pressure, they may be passed by, for as a rule such conditions are not consistent with durability, hence their importance is very restricted.

ACTIVITY

Any activity is possible provided a suitable system exists and provided suitable energy is present. This fact leads us back to the conclusion that chemical transformations of hydrogen, oxygen and carbon are the very best chemical means of storing and liberating energy, and that the reactions of organic compounds permit the most delicate adjustments of such transformations. Further it has been shown that the unique thermal properties of water are most highly suited to the storing and distribution of energy, while its solvent power facilitates osmotic pressure and diffusion. It may also be mentioned as a final instance of fitness for activity, among many other examples, that the electro-chemical characteristics of water are in many ways the best possible sources of electrical activity.

DURABILITY

Durability depends upon stability of conditions and upon supplies of matter and energy to replace what is used up.

The stability of physico-chemical conditions, which is due to the presence of water and carbonic acid as primary constituents of the environment, is very great indeed, and, beyond doubt, far greater than what could exist if these substances were replaced by any others. A very large part of all the data of oceanography and meteorology do but illustrate the almost inconceivable efficiency with which water, in the main through its unique thermal properties, completely checks very wide ranges of temperature, and as a rule restricts the

range of temperature within narrow limits in the waters and throughout the earth. Even more exact is the regulation of the alkalinity of the ocean by means of carbonic acid, through its unique solubility and ionizing power. These are but two among many examples of maximal efficiency in regulation.

The renewal of matter and energy are not less highly favored. The properties of water ensure everywhere the highest availability of supplies in the greatest number and concentration. Further the three elements carry with them the possibility of maximal energy supplies. In some respects, indeed, the ubiquity and mobility of water and carbonic acid, their presence in the sea, in the lakes and streams, in the air, and in the soil, which depend upon the combined action of the unique solubility of carbonic acid, the unique vapor tension of water, and its unique surface tension, seem the most remarkable of all fitnesses.

I can not further develop these considerations here, for they are too numerous and too varied, but I have elsewhere treated them extensively.³ In truth, all the properties of water, of carbonic acid, of the compounds of carbon, hydrogen and oxygen, of the ocean, and of the meteorological process, so far as the present state of science permits their analysis, need to be considered, for each adds to the argument. Each contributes to duration, or to activity, or to the phases, or compounds, or concentrations of possible systems. Each tends to increase rather than to restrict the possibilities of mechanism, and each is the best, or nearly the best, among all the known substances in the world. And the ensemble of these properties is perfectly and extraordinarily unique.

All of these relationships are merely physical, nothing about them is biological except their importance.

From such considerations there can be but one conclusion: the unique ensemble of properties of water, carbonic acid and the three elements constitutes among the properties of matter the fittest ensemble of characteristics for durable mechanism. No other environment, that is to say no environment other than the surface of a planet upon which water and

carbonic acid are the primary constituents, could so highly favor the widest range of durability and activity in the widest range of material systems—in systems varying with respect to phases, to components, and to concentrations. This environment is indeed the *fittest*. It has a claim to the use of the superlative based upon quantitative measurement and exhaustive treatment, which is altogether lacking in the case of the fitness of the organism. For the organism, so we fondly hope, is ever becoming more fit, and the law of evolution is the survival of the fitter.

Yet it is only for mechanism in general, and not for any special form of mechanism, whether life as we know it, or a steam engine, that this environment is fittest. The ocean, for example, fits mechanism in general; also, if you will, it fits the whale and the plankton diatom, but not man or a butterfly. But, of course, as everybody has known since 1859, it is really the whale and the diatom which fit the ocean. And this leads to the true conclusion of our investigation.

Just because life must manifest itself in and through mechanism, just because, being in this world, it must inhabit a more or less durable, more or less active physico-chemical system of more or less complexity in its phases, components and concentrations, it is conditioned. The inorganic, such as it is, imposes certain conditions upon the organic. Accordingly, our conclusion is this: *The special characteristics of the inorganic are the fittest for those general characteristics of the organic which the general characteristics of the inorganic impose upon the organic.* This is the one side of reciprocal biological fitness. The other side may be similarly stated: Through adaptation the special characteristics of the organic come to fit the special characteristics of a particular environment, to fit, not any planet, but a little corner of the earth.

LAWRENCE J. HENDERSON

HARVARD UNIVERSITY

THE PITTSBURGH EXPERIMENT STATION OF THE BUREAU OF MINES

PLANS for the proposed \$500,000 experiment station of the United States Bureau of

³ See "The Fitness of the Environment."

Mines to be located in Pittsburgh, Pa., have been approved by the commission appointed by congress for that purpose. The federal government now owns the property upon which will be erected a group of buildings, especially designed and adapted for the carrying on of the mine safety work and other investigations in which the Bureau of Mines is interested.

Congress a year ago, in the public buildings bill, authorized a new home for the Bureau of Mines to cost \$500,000. It is now expected that congress in its present session will make a specific appropriation so that construction work may begin. It is hoped that contracts may be let by July 1. The director is hopeful that the buildings may be completed in the fall of 1915, when they will be dedicated with suitable ceremony, including a second National Mine Safety Demonstration, similar to that held at Pittsburgh in 1911.

The commission which has approved the plans consists of J. A. Holmes, D. C. Kingman, chief of engineers of the United States army and O. Wenderoth, supervising architect of the treasury. The state of Pennsylvania has appropriated \$25,000 for cooperation in establishing this experiment station and has appointed a state commission consisting of James E. Roderick, chief mine inspector, Dean W. R. Crane, of the mining department, Pennsylvania State College, and W. H. Caverly. This latter commission has tentatively approved the plans.

The buildings which will constitute the experiment station of the bureau will form a part of a most remarkable and unusual group of monumental edifices devoted to educational purposes. On one side the bureau's buildings will face the great group of structures of the Carnegie School of Technology. On another side is the Carnegie Institute, in which are the art gallery, museum and library. Nearby is the imposing pile of buildings of the University of Pittsburgh. Other nearby buildings are the Memorial Hall, Pittsburgh Athletic and University Club and the Hotel Schenley. The site consists of nearly twelve acres of land, part of it on the higher level

of the city streets and part of it on the level of the B. & O. Railroad, which railroad will furnish adequate facilities for passengers and freight traffic.

The group consists of three main buildings facing Forbes Street and the several street-car lines from the uptown district. The central building of the group, the mining building, will be three stories in height, flanked by two main buildings, one the mechanical and the other the chemical building. In the rear of these and inclosing a court will be the service building. Beyond the service building and spanning what is known as Panther Hollow and thus connecting the Bureau of Mines buildings with the Carnegie Schools, will be two buildings over the roofs of which will pass the roadway from Forbes Street to the Carnegie School buildings and Schenley Park.

Between the main group and the power and fuel group will be the entrance to a series of mine shafts. One of these will be used as an elevator to carry heavy material and passengers from the lower level to the upper; another will be for tests of hoisting ropes and similar mining appliances; another will be an entrance to tunnels extending under the buildings and in which mining experiments, such as fighting mine fires, will be conducted.

The portion of Panther Hollow above the power buildings will be arranged as a miners' field, the slopes of the ravine being utilized as an amphitheater which will accommodate 20,000 spectators who may assemble here to witness demonstrations and tests in mine rescue and first-aid.

The main or mining building will contain the administrative offices, and those of the mining force. In it will be an assembly and lecture hall, a library and smoke and other rooms for demonstrations and training in mine rescue and first-aid. The mechanical building will be for experiments and tests of mining machinery and appliances and the chemical building for investigation and analyses of fuels, explosives and various mineral substances.

The buildings now used by the Bureau of Mines as an experiment station at Pittsburgh

were loaned to the bureau by the War Department as an emergency measure when the bureau was created. The War Department has suggested that it now needs these buildings and it is felt the bureau can not retain possession much longer. The buildings are very old and are entirely unsuited to the needs of the Bureau of Mines work. It is said that the investigations have been seriously handicapped by the inadequacy of the structures now in use.

THE FUR-SEAL COMMISSION

THE President of the United States and the Secretary of Commerce have approved the recommendation of the Commissioner of Fisheries for the appointment of a special fur-seal commission, to visit the Pribilof Islands during the present season for the purpose of advising the government as to the condition of the seal herd and of making recommendations regarding the policy that should be adopted with reference thereto.

The members of the commission, in accordance with the suggestion of the Commissioner of Fisheries, have been selected by outside agencies and have had no previous connection with the fur-seal controversy.

In response to a request that a duly qualified assistant of the Department of Agriculture, versed in the breeding and other habits of wild and domestic animals, be designated to serve as a member of the commission, Mr. Edward A. Preble, assistant biologist of the Bureau of Biological Survey, has been nominated by the Secretary of Agriculture.

The Secretary of the Smithsonian Institution was requested to name, as a second member of the commission, a person duly qualified to make a critical study of the economic relations and obligations of the government toward the fur-seal herd, the natives of the seal islands, and the fur trade. Mr. Wilfred H. Osgood, of the Field Museum of Natural History, Chicago, has been chosen for this purpose.

The President invoked the National Academy of Sciences to nominate as a third member of the commission a person qualified to study

the scientific and economic questions involved in the administration of the seal herd; and Dr. George H. Parker, of Harvard University, has been duly nominated.

Arrangements have been made for sending the commissioners to and from the seal islands on a revenue cutter; they will arrive in the latter part of June and will remain until the second week in August, thus covering the most critical periods of the land life of the seals.

SCIENTIFIC NOTES AND NEWS

THE spring meeting of the council of the American Association for the Advancement of Science will be held at the Cosmos Club, Washington, D. C., on the afternoon of Tuesday, April 21, at 4:45 o'clock.

At the general meeting of the American Philosophical Society, held at Philadelphia from April 23 to 25, there will be presented to the society a portrait of the late Samuel Pierpont Langley, a former vice-president.

As has already been noted in SCIENCE, the American Chemical Society is holding its spring meeting at Cincinnati, Ohio, during the present week. Each of the sections has a full and important program. At the general session on the first day, after addresses of welcome by the mayor of the city and the president of the University of Cincinnati, and a reply by the president of the society, Professor Theodore W. Richards, the following papers were announced: Arthur L. Day, "The Chemical Problems of an Active Volcano"; L. J. Henderson, "The Chemical Fitness of the World for Life"; W. D. Bancroft, "Flame Reactions"; Irving Langmuir, "Chemical Reactions at Low Pressures."

A PORTRAIT of Sir William Ramsay, painted by Mr. Mark Milbanke, has been presented to University College, London, by former colleagues and past students. Professor J. Norman Collie made the address. A replica of the portrait has been presented to Lady Ramsay.

PROFESSOR JOHN F. DOWNEY, dean of the college of science, literature and the arts, of the University of Minnesota and professor of

mathematics, will retire in June, 1913, after thirty-three years of service as a member of the Minnesota faculty.

THE Cambridge University observatory syndicate has appointed Professor A. S. Eddington, Plumian professor of astronomy, to be director of the observatory.

MR. ARTHUR SCOTT, for some years past a teacher of science in Chili, has been appointed assistant in the Lick Observatory, on the D. O. Mills Foundation, for service in the work of the D. O. Mills Southern Hemisphere Expedition, which at Santiago, through the gift of Mr. Ogden Mills, of New York, is carrying on extensive studies in the movement of stars in the line of sight.

WE learn from *Nature* that the first award of the Kelvin gold medal and prize, founded by Lady Kelvin at the University of Glasgow for the best dissertation in natural philosophy presented for the degree of D.Sc. during the three years 1911-13, has been made to Dr. A. D. Ross, now professor in the University of Western Australia. The first award of the William Jack prize (founded in honor of Emeritus Professor Jack), for the best dissertation in mathematics presented for the degree of D.Sc. during the four years 1910-1913, has been made to Dr. R. J. T. Bell, senior university lecturer in mathematics.

PROFESSOR JOHN ZELENY, head of the department of physics of the University of Minnesota, has been granted a year's leave of absence, which he will spend in private study and research at Cambridge, England. Professor Anthony Zeleny will act as chairman of the departments during the year 1914-15.

PROFESSOR LUDWIG PICK, of Berlin, will deliver the Harrington lectures of the medical department of the University of Buffalo, under the title of "Some Advances in Pathological Anatomy."

DR. LIGHTNER WITMER, of the University of Pennsylvania, and Professor L. O. Coffman, of the University of Illinois, were the principal lecturers at a week's conference of principals and superintendents of city schools, held at the University of Minnesota, March 23-28, with a registration of about 300.

THE Bakerian Lecture of the Royal Society was delivered by Professor A. Fowler on April 2, on "Series Lines in Spark Spectra."

DR. EGBERT LE FEVRE, dean of University and Bellevue Hospital Medical College, New York City, died on March 30, from scarlet fever, aged fifty-five years.

DR. JOHN HENRY POYNTING, professor of physics at Birmingham University, has died at the age of sixty-one years.

PROFESSOR G. M. MINCHIN, F.R.S., formerly professor of mathematics, Royal Indian Engineering College, Coopers Hill, died on March 23, at the age of sixty-eight years.

DR. G. J. BURCH, F.R.S., formerly professor of physics at University College, Reading, has died at the age of sixty-two years.

PROFESSOR G. JOACHIMSTHAL, of Berlin, chief of the university clinic for orthopedic surgery, has died at the age of fifty years.

THE *London Times* reports that Sir John Murray, the oceanographer, who was killed in a motor-car accident on March 16, has by his will bequeathed his books, papers, letters, collections, specimens, furniture, fittings, instruments, and such effects in his Challenger Office at the Villa Medusa, Wordie, Edinburgh, as also the books, etc., property belonging to his scientific library in Challenger Lodge at the time of his death, to his son, whom failing, to his daughters, along with a number of shares in the Christmas Island Phosphate Company, in order that the dividends may be applied in scientific research or investigations or explorations which are likely to lead to an increase of natural knowledge, and especially in the science of oceanography. He expressed the wish that his deep-sea collection of marine deposits and scientific library should be kept together and be cared for by his sons or daughters, the Villa Medusa being used for the purpose, so that scientific work might be carried on there for 20 years after his death. It is suggested that in the case of substantial expenditure the Challenger Society or the Royal Society of London or the Royal Society of Edinburgh might be consulted.

To search the Arctic Circle for the lost Canadian exploration ship *Karluk* the steam whaler *Herman* has left San Francisco. The Canadian government is sending the whaler to the relief of the *Karluk*, which with the greater part of her crew has been missing for several months. It will be remembered that Mr. Stefansson, commander of the expedition, who with three of the crew left the *Karluk* which was fast in the ice, to hunt caribou, could find no trace of the vessel when they returned. The ice had been broken up by a gale and the ship, it is supposed, drifted eastward. Captain C. T. Pedersen, master of the *Herman*, believes he will find the *Karluk* somewhere between Point Barrow and Herschall Island, locked among icebergs.

Nature states that while the various official and private expeditions are making preparations for observing the total solar eclipse of August 21 next, steamship companies are offering pleasure cruises which include a stay on the line of totality on the Norwegian coast. The Royal Mail Steam Packet Company's ocean yachting steamer, *Arcadian*, twin screw, and 8,939 gross tonnage, is timed to leave Grimsby on August 15 and Leith, August 16, and will take up a position near Alsten, north of Torghattan Island, well on the central line. The Norway Travel Bureau of the Great Northern Railway Company has also arranged a special cruise. Passengers leave Newcastle-on-Tyne by the steamship *Venus* on August 15, and join the special steamer *Mira* at Bergen on August 17, a position being taken up at Stokka on eclipse day. It is stated that if a party of seventy-five to eighty members of the Royal Astronomical Society and the British Astronomical Association would avail themselves of this facility no other passengers would be accepted, and the itinerary would be varied to meet the requirements of the party, and the stay at any place in the eclipse zone prolonged.

THE Association of Dental Faculties of American Universities met at the University of Minnesota, March 20-21. Dean Owre, of Minnesota, read a paper recommending the adoption by this association of a four-year

course in dentistry for all the colleges composing the association. This recommendation was adopted. The deans present at the meeting were: Frank T. Breene, Iowa State College; Edward C. Kirk, University of Pennsylvania; James Sharp, University of California; F. B. Moorehead, University of Illinois, and W. S. C. Hoff, University of Michigan. In addition there were present several members of the faculties of the institutions represented. The dental college of Washington University, St. Louis, Dr. J. H. Kemmerly, delegate, was admitted to membership.

WORK is now in progress at the University of Chicago on a building for the Departments of Geology and Geography to be known as the Julius Rosenwald Hall. It will be made of stone, steel and cement and be fireproof in the best sense of the term. The cost will be about \$260,000, exclusive of the furniture and equipment. It adjoins Walker Museum and will be connected with it by corridors on each floor. Both buildings will be served by an elevator in the corridor connection. As the plans have been carefully drawn on the basis of large experience, the following list of the appointments may be of interest to geologists and geographers: A museum room, an assembly hall, six class rooms, a seminar room, laboratories for mineralogy, petrology, economic geology, geo-chemistry, macroscopic determination, ore genesis, high temperature and high pressure experiments (outside the main walls of the building), physiographic modeling, dynamical and structural experimentation, lathe and section work, and miscellaneous work, a laboratory-conference room, a seismograph room (with pier carried down to solid rock by caisson), a vault for documents and rare material, three map laboratories with three associated map-conference rooms, a general departmental reading room with accommodations for eighty, a stack room for departmental library with capacity for 66,000 books, with book-lift, and a library work room; a research reading room, five research study-rooms for staff, a staff research room each for geology and for geography, ten research rooms for candidates for Ph.D., a council room, nine

offices for staff, a stenographer's room, a waiting room, a meteorological tower, with a laboratory, a work room and an office, three dark rooms, a goniometer room, a microphotographic room, a room for liquid separation of minerals, five storage rooms, five storage closets connected with class rooms, cloak rooms, lockers and four toilet rooms. The ventilation will be forced by an electric fan in the basement supported by a suction fan near the roof. The exterior of the building will be ornamented with symbolic bas-reliefs representing subjects appropriate to the earth sciences, as well as some of the great leaders in special phases of the science. The contract calls for the completion of the building by the first of November. The paleontologic work will remain in Walker Museum and the two buildings will be used in close relationship.

THE water supply of the great Missouri River drainage area is the subject of a publication recently issued by the United States Geological Survey, entitled "Surface Water Supply of the Missouri River Basin, 1911," by W. A. Lamb, W. B. Freeman and Raymond Richards. This report contains the records of flow at 130 permanent stations of the survey during the year 1911, data which are necessary to every form of water development, whether it be water power, navigation, irrigation or domestic water supply. Some of the tributary streams are exceedingly variable in flow; others, like the Niobrara in Nebraska, are remarkably uniform. A systematic study of Missouri River and its tributaries is being carried on by the United States Geological Survey. Considering the varied character of the streams of the Missouri River basin and their great economic importance for irrigation, power and other purposes, the investigation is one of importance. The Missouri proper is formed in southwestern Montana by the junction of three streams which were discovered by Lewis and Clark in 1806 and were named by them Jefferson, Madison and Gallatin Rivers. Of these three Jefferson River drains the largest area and is considered the continuation of the main stream. This part of Montana is mountainous and affords many

excellent water-power sites. Among the principal tributaries of the Missouri are the Marias, Musselshell, Yellowstone, Cheyenne, Platte and Kansas. The western part of the basin is in the arid belt and the eastern part is in the semiarid and humid regions. Ten states are drained in part by Missouri River. Rising at the Red Rock Lakes, at an elevation of 6,700 feet above sea level, this stream descends through the Rocky Mountains and emerges on the broad prairie land a few miles below the city of Great Falls, Mont. From that point it is accounted a navigable stream with an easy grade, and in passing through the Dakotas and along the borders of Nebraska, Kansas and Iowa it receives the flow of great tributaries, so that as it crosses the State of Missouri and joins the Mississippi a short distance above St. Louis, it becomes one of the large rivers of the world. Its total drainage area is about 492,000 square miles in extent and comprises, in addition to the states above mentioned, large areas in Wyoming and Colorado and a smaller area in the southwestern part of Minnesota. On Shoshone River in Wyoming, a tributary of the Bighorn, which in turn is tributary to the Yellowstone, which joins the Missouri in eastern Montana, is located the Shoshone dam, the highest structure of its kind in the world, 328 feet from foundation to capstone. This structure was erected by the government to impound water for irrigation on the arid lands in the valley of Shoshone River below. Another great structure of a similar kind is located in Wyoming on North Platte River, which joins the Missouri near Omaha, Nebr. This is known as the Pathfinder dam, and was also erected by the government to impound water for use in the irrigation of lands in Wyoming and Nebraska. Another notable engineering structure in the drainage basin of the Missouri River is the Belle Fourche dam, erected across the river of the same name in South Dakota by the government to impound water for irrigation. This dam is an earth embankment 155 feet high and one and one fifth miles long, containing 1,600,000 cubic yards of earth fill. This is the largest earth dam in existence.

UNIVERSITY AND EDUCATIONAL NEWS

A CONTRIBUTION of \$50,000 from Mrs. E. H. Harriman to the endowment fund of Barnard College, Columbia University, is announced toward the million dollar fund now being raised for the twenty-fifth anniversary of the institution \$550,000 is now pledged.

DR. J. B. JOHNSTON, professor of neurology in the department of anatomy of the University of Minnesota, has been appointed professor in the department of animal biology in the College of Science, Literature and the Arts, and dean of that college from August 1, 1914.

RICHARD LABAN ADAMS, a graduate of Massachusetts Agricultural College and M.S. of the University of California, has been appointed assistant professor of agronomy in the University of California. James Alexander Armstrong, a graduate of 1910 of the University of California, and now chief chemist of the Union Sugar Company at Betteravia, California, has been appointed field assistant in agricultural extension in the university.

DR. E. G. KENNARD, of Cornell University, has been appointed instructor in physics at the University of Minnesota.

MR. A. V. HILL has been appointed to the Humphrey Owen Jones lectureship in physical chemistry, at the University of Cambridge.

DISCUSSION AND CORRESPONDENCE

GYROSCOPIC QUANTA

IN the note¹ on gravitationally produced vortices in the ether and their relation to Planck's quantum theory, attention should perhaps have been called to some additional deductions.

For example, that it necessarily follows from the writer's electrostatic-doublet vortex theory of matter,² that the energy radiated when a distortional ether wave strikes an

atom will be given off in quanta and be proportional to the frequency.

The simplest way of seeing this is to take the well-known experiment in which a gyroscope is held in the hand and the body revolved first in one direction and then in the other. On turning the body in one direction no effect is produced on the gyroscope. On turning in the other direction the gyroscope resists and is upset, and the axis then points in the opposite direction.

It may easily be shown that the amount of work done in upsetting the gyroscope varies directly as the angular velocity of rotation of the body, *i. e.*, in the case of the atom and ether wave, is directly proportional to the frequency.

It will be seen that this type of atom is somewhat different from any of those heretofore proposed. For example, instead of the electrons being numerically equal to one half the atomic weight the electrons can be numerically equal to the atomic weight, but only one half of them affected by any given ether displacement.

In addition, the stable equilibrium conditions of this type of atom are comparatively simple and the positive nucleus may be made to vanish, *i. e.*, can be formed of a number of negative electrons as pointed out in a previous paper.

MULTIPLE FACTORS IN HUMAN SKIN COLOR

A RECENT article by E. C. MacDowell¹ on "Multiple Factors in Mendelian Inheritance" is highly significant in its explanation of cases of apparently "blended" inheritance. The author gives a clear historical summary of experiments made by various investigators, beginning with Nilsson-Ehle's studies on oats and wheat first published in 1909. The original work reported is upon sizes in rabbit hybrids. It is a continuation of Castle's well-

¹ SCIENCE, October 17, 1913.

² See papers referred to 1889-1900 in previous note.

¹ *Jour. Exper. Zoology*, Vol. XVI, No. 2, pp. 177-194, 1914.

known studies and was carried out with Castle's own material and with his cooperation and help. The experiments now reported show that the Nilsson-Ehle explanation of "blended" inheritance (*i. e.*, two or more non-allelomorphic factors producing phenotypically similar phenomena) may be applied to size differences in hybrid rabbits.

The fact that crosses between negroes and whites give mulattoes has long been pointed to as proof of "blending." But, as is well known, various pigments are here involved, viz., black, red and yellow. Davenport² has shown clearly that the children of two mulatto parents exhibit great variation in color. Occasionally some are light enough to "pass for whites" when away from home. The explanation of this phenomenon, as based on multiple factors, is suggested by Davenport. In the light of MacDowell's own work and the work that he cites there can be little doubt of the correctness of this view. Probably there are separate factors (determiners) for the several pigments and more than one, perhaps many, for the black pigment.

A quotation from MacDowell's paper shows the conclusions drawn from his studies of rabbits. But his statements may be applied to human skin color and, no doubt, to many heritable characters of human beings:

Offspring from crosses between extremes are generally of an intermediate nature. In the following generation new forms appear that are similar to the original parents or even more extreme. The greater number of individuals are intermediate. In certain cases crosses between similar lines, after a first generation like the parents, give a second generation in which a wide range of grades appear. These are the facts definitely ascertained from the work that has been done. . . . The interpretation of multiple factors can be applied to all the facts. It goes hand in hand with the mutation and pure-line doctrines of de Vries and Johannsen, and in its breadth of application, and its comprehensive simplicity, this theory, based on the assumption of the segregation of distinct units, is very attractive; by its use as a working hypothesis important facts have been discovered;

² "Heredity in Relation to Eugenics," pp. 36-38, New York, 1911.

its acceptance and further development will help to establish a broad and unified system of heredity.

Doubtless many "well-informed" persons still hold to the idea of "blended" inheritance. It is with the hope of calling attention to the Mendelian phenomena involved that this note is submitted. A careful reading of MacDowell's article will clear up many puzzling difficulties for those who are interested in heredity but have not kept up with the literature of the past few years.

FRANCIS RAMALEY
UNIVERSITY OF COLORADO,
BOULDER, COLO.

DIADOPHIS PUNCTATA IN NORTHERN WISCONSIN

RUTHVEN¹ has recorded the occurrence of the ring-necked snake, *Diadophis punctata* (Linnaeus), at Marquette, Michigan, on the strength of specimens having "been taken by Dr. Downing," but later the same authority states: "The Marquette record is particularly open to question and has not been recorded upon the map." Not having seen a specimen from Marquette, Ruthven was perfectly justified in making his later statement, in view of the fact that the locality was considerably beyond the known northern geographic range of the species. It may be interesting, however, in this connection to note that on July 5, 1912, I collected a specimen of this species near Rhinelander, Oneida county, Wisconsin, a locality about 120 miles west-southwest of Marquette, Michigan. The snake was found, one and one half hours after sunset, extended full length across the wheel tracks of a sandy road bordering low second-growth woods of *Pinus divaricata*, *Betula papyrifera*, *Populus tremuloides* and *Quercus coccinea*; in the late twilight the animal was scarcely visible from the wagon in which I was driving. It made no resistance to being captured, was perfectly docile, and soon became tame. It showed a tendency towards positive reaction to contact

¹ Ruthven, A. G., 1906, Report Geol. Surv. Michigan for 1905, p. 111.

² Ruthven, A. G., Thompson, C. and Thompson, H., 1912, "The Herpetology of Michigan," Michigan Geol. and Biol. Surv., publ. 10, p. 107.

stimuli and a negative reaction to strong light, factors which may, in part, determine the nocturnal and hiding habits of this species. Unfortunately I was not favorably situated at the time for an extensive study of the habits and behavior of the animal, and it was, therefore, the next day preserved as a specimen.

On account of the rarity of this species in the northern part of its geographic range it seems that a brief description of this specimen is not amiss. The general color of the back can best be described as dark bluish olive-brown; the ventral parts, labials and neck-band (two scales wide) are salmon pink, being slightly darker postero-ventrally and slightly more yellowish on the supralabials and neck-band; a series of about 40 small black spots are scattered irregularly in a single midventral line from the 41st to the 144th ventral plates, being more numerous between the 86th and 144th ventral plates. The total length is 335 mm.; tail, 80 mm. The scutellation is as follows: dorsal scale rows, 15; ventrals, 156; subcaudals, 53; supralabials, 8-8; infralabials, 8-7; oculars, 2-2; temporals, 1-1.

HARTLEY H. T. JACKSON

U. S. DEPARTMENT AGRICULTURE

SCIENTIFIC INSTITUTIONS MINUS SCIENCE

IN recent years the question has much occupied the public mind whether fraternities in schools and colleges are desirable or not. Those who favor the negative, often point to the low scholarship of the members of fraternities. The fraternities have reacted by strenuous efforts to raise the scholarship among their members. One of the national organizations recently offered a loving cup to that chapter in a group of universities of the Middle West which would make during the year the highest scholarship record. The national officers asked two members of the faculty of the University of Missouri to select the chapter. That ought to be easy. But it was found impossible. To make such an award, it is not sufficient to know that each chapter got so many A's, B's etc., or so many 95's, 90's, etc., whatever the symbols may be in each institution. It is absolutely necessary

to know the frequencies of these grades in the whole student body of the institution. But none of these institutions, except one, could furnish these data, although, without the frequencies being known, their grades are practically meaningless. Here, then, we have institutions which are generally regarded as the representatives of science. But to apply science to the grades, of which they record year after year thousands, and without which they appear to be unable to get along, that does not seem to have occurred to the administrations of most of them. Their alumni look with amazement upon their *alma maters* which can not furnish the data for the solution of so simple and so proper a problem as that of awarding a loving cup to a group of students who have distinguished themselves by their scholarship.

MAX MEYER

UNIVERSITY OF MISSOURI

THE LANGUAGE OF THE BRAZILIAN PEOPLE

TO THE EDITOR OF SCIENCE: Regarding the review of the work entitled "Fossei Devonianos Do Paraná," published in the March 13 issue of SCIENCE by Dr. Chas. K. Swartz, Baltimore, Md., in the last paragraph where it mentions the work done by Dr. John M. Clarke, for the Department of Agriculture, Commerce and Industry (Geological and Mineralogical), I find a mistake in his stating that the work is published in the English and Spanish languages in parallel columns. Mr. Swartz should have said that it is published in Portuguese and English, the former being the universal language of the Brazilian people.

E. BRAGA

QUOTATIONS

PROFESSORS IN COUNCIL

IN the circular letter that was sent out in the spring of 1913, looking to the formation of a national association of university professors, the motive actuating the signers was indicated in the statement that, besides his interest in his specialty, the university professor is "concerned, as a member of the legis-

lative body of his local institution, with many questions of educational policy which are of more than local significance"; also that "he is a member of a professional body which is the special custodian of certain ideals, and the organ for the performance of certain functions essential to the well-being of society." And the general purposes were declared to be "to promote a more general and methodical discussion of the educational problems of the university; to create means for the authoritative expression of the public opinion of the profession; and to make possible collective action, on occasions when such action seems called for." The letter was sent out by Johns Hopkins professors to members of the faculties of nine other universities, and the response was favorable in all cases; a conference on the subject was held last November; and now announcement is made of the names of a committee, representing the chief departments of learning and nearly all the leading universities of the country, whose task it will be to take the steps necessary for complete organization.

The distinctive feature of the American university is the part played by the president. Nothing even distantly resembling it exists, we believe, in any European country. That he is not the absolute monarch he is sometimes represented as being is true enough; but the limitations upon his power are often of the same nature as those which have as a general rule obtained in the case of what are usually designated as absolute monarchies in the history of nations. No university president thinks of setting up his personal will as the sole guide of his policy. Apart altogether from such check as may be exercised by the board of trustees, or other formal governing body, he usually consults the chief professors in any matter relating to their respective departments; and moreover there exists in every university some form or other of faculty organization. Nevertheless, the president, in most American universities, is the center of power, the chief fountain of favor and disfavor, of advancement or retardation; and his disposition towards any question, whether

relating to an individual or to a principle or a policy, usually has, or may have if he chooses, the controlling influence in its determination.

This feature of the American university system has been the subject of endless comment; but there exists alongside it, and somewhat resembling it in nature and effect, another feature that has attracted less notice. What goes on within any university is, in a certain sense, its own private affair; and it may easily happen that it is not the president, but one or more professors or professorial cliques, in whom real power rests, and by whom it is improperly exercised. Now there has not been developed in our country either any central organ—such as the Ministry of Public Instruction in European countries, for example—or any well-defined body of university tradition, to operate as a check upon any bad tendencies or unjust practices which may thus develop in any given institution. When such a state of things arises, whether the blame for it belongs to president or to professors, all that is apt to happen is a certain amount of grumbling, perhaps of indignation; it is only in extreme cases that there is likely to be any overt action. It may be that some professor is the victim of downright persecution; it may be that manageable mediocrity is systematically preferred to high ability which is somewhat more difficult to handle; it may be that independence of thought or freedom of speech is frowned upon and discouraged. Whatever the trouble may be, appeal is impossible to any but the little circle within the university itself, which is to all intents and purposes a close corporation.

That the new association may supply to the American university professor a basis for a wider and more catholic appeal in questions of moment, that it may become the means of promoting a professional spirit at once finer and stronger than that which has hitherto been general, must be the hope of all who are interested in the most truly distinctive service which universities render to a nation. Upon their immediate promotion of the general welfare, not only through the diffusion of intelligence and the improvement of education, but

also through efforts expressly directed to economic and social ends, emphasis has been laid in these latter days as never before. This tendency is bound to continue; and the benefits that will flow from our universities in these ways are quite beyond calculation. But it is not difficult to imagine these results obtained by other instrumentalities, if the institution we call the university were not historically in existence, and ready to furnish them. The thing that the university alone can supply—the thing, at all events, for which neither history nor imagination suggests a possible substitute—is the preservation of high intellectual ideals, the maintenance of noble traditions of science and learning. Of these ideals and traditions university presidents, however masterful, university administrators, however efficient, can not possibly serve as the custodians. It is upon the men whose business is not to administer but to teach and to learn, not to manage but to investigate and to inspire, that we must depend for the keeping alive of the sacred fire. And if we read aright the announcement of its purposes, it is to the strengthening of this conception of the professor's status that the new association is above all to be devoted.—New York *Evening Post*.

SCIENTIFIC BOOKS

The Scientific Work of Morris Loeb. Edited by THEODORE W. RICHARDS. Harvard University Press. 1913.

The many friends of Dr. Morris Loeb will feel very grateful to Professor Theodore W. Richards for arranging this volume. It is the best monument yet erected to the memory of a man whose life was an inspiration to all who knew him.

The first part of the volume is a collection of some lectures and addresses referring to chemical research, the Chemists' Club building, the chemical museum and kindred subjects. The great idealism of Dr. Morris Loeb, combined with his practical, well-organized methods and conceptions, are well illustrated by some passages:

Pages 95-96: ". . . How, then, can the

status of the independent commercial chemist be raised in our city? By giving him a central rally-point; a home that proves to the layman that his is a skilled profession, not a mere job-hunting trade; a place where the manufacturer or merchant can find the man he wants without a rambling search through the city directory. Doubtless, some of our colleagues are so well known that all the business comes to them which they can handle. But the many additional independent chemists, whom our commercial situation demands, can only establish themselves if they can secure proper laboratory facilities, without hiring attics in tumble-down rookeries. . . ."

Page 96: ". . . Every year scores of New Yorkers graduate in chemistry from our local institutions and return from years of protracted study in other American and European institutions. They are enthusiastic for research; in completing their theses they have laid aside definite ideas for subsequent experimentation; but they have no laboratory. While waiting to hear from the teachers' agency where they have registered, while carrying on desultory correspondence with manufacturers who *may* give them a chance, they do not venture upon expenditure of time and money to fit out a private laboratory, which they may be called upon to quit any minute upon the appearance of that desired appointment. Often necessity or tedium will cause them to accept temporary work of an entirely different character and indefinitely postpone the execution of the experiments which they had mapped out. Who will estimate the loss of scientific momentum, the economic and intellectual waste, which this lack of laboratory facilities for the graduate inflicts upon New York, as compared with Berlin, Vienna, Paris and London? Either our universities and colleges, or private enterprise, should provide temporary desk-room for the independent research chemist."

Pages 98-99-100: ". . . There is still another point, however, in which the American chemist is at a great disadvantage as compared with the European; the ease of securing material for his research and of comparing his

results with those of others. In Europe, especially in Germany, research is never seriously delayed by lack of a needed preparation, whereas, none of our supply houses carry a full stock of chemicals. To obtain a single gram of some particular substance, needed for a few preliminary tests, frequently causes weeks of delay, as well as the disproportionate custom house and brokerage expenses involved in the importation of small quantities. Besides, owing to the better centralization of scientific laboratories in Europe, and the existence in each case of a fairly complete set of specimens accumulated in the researches of large numbers of academic investigators, it is comparatively easy to obtain by correspondence research material or typical specimens for comparison. In this country, on the other hand, laboratories are scattered throughout the numerous colleges and universities, and there are no established rules by which specimens must be deposited with the laboratory. In smaller laboratories, especially, the chances of preservation after the departure of the investigator are not very good. It would be, consequently, very much more difficult to obtain such specimens here. I would suggest, therefore, that a chemical museum be established in New York, to perform for the American chemists the functions that the Smithsonian Institution so admirably carries on for the benefit of American naturalists. This museum would not attempt to be a popular show-place, but would embody, in the first place, as complete a collection as possible of chemically pure materials of the rarer kinds, so as to supplement, but not in any manner compete with, the stock of commercial supply-houses. Any scientific investigator would be entitled to borrow or purchase material required for immediate experimentation, and all used articles would be replaced as quickly as possible.

In the second place, it would be a depository for specimens of new substances obtained in American research. Every chemist would be invited to send to the museum a small quantity of each substance newly prepared by him, not, indeed, as an evidence of the good faith

of his investigation, but, rather, to enable future workers to obtain such material, either for comparison, or for further experimentation with the least possible delay. Many substances that are now carried away from universities by students who subsequently abandon chemical research, or which belong to the families of deceased chemists who do not know what to do with them, would thereby be rescued from oblivion, and might ultimately become of the greatest value for a special purpose.

Thirdly, this museum would invite chemical manufacturers to send standard samples of their products, and thereby facilitate the commercial relations between consumer and manufacturer.

To such a museum there could be attached a competent staff of workers for the preparation of samples not otherwise available. In the analysis of samples submitted as official standards, we should have the beginning of that *Chemische Reichsanstalt* which is now the chief object to which German chemists are directing their attention."

Page 126: ". . . We have detailed some of the more striking advantages which the new building is expected to confer upon the chemical profession as a whole, as well as upon its individual votaries; is it an exaggeration to characterize the constitution of the *Chemists' Building Company* itself as a new era in the chemical industry of our country? In scanning the list of shareholders, we find representatives of nearly every important concern, or even the larger companies themselves; but that this is not a 'trust,' in the sense so obnoxious to the yellow journalist, is demonstrated by the conditions of the partnership. No shareholder can receive more than 3 per cent. dividends, and the surplus can not, under any circumstances, accrue to his benefit within the next fifty years. This association, therefore, is not for individual profit, but for the raising of the standards of chemical industry and research in the United States. If we recognize what the *Verein zur Hebung der chemischen Industrie*, founded by *Hofmann* and *Werner Siemens*, has done for

Germany, we may well hope for further fruits of this initiative here. Perhaps this building will house joint laboratories for the solution of questions affecting all manufactures alike; or experimental stations for the study of natural products not yet utilized; or a cooperative bureau of standardization for analytical methods; or a national welfare bureau for employees in chemical factories. This building does not owe its erection to some benevolent demigod, extending his protecting wing over people unable to care for themselves; it is a building by the chemists, of the chemists, and for the chemists. May it ever serve as an exemplar of unselfish patriotic cooperation!"

Pages 128-129: "... For, strange as it may seem to the layman, who has seen the ugliest blots on a landscape designated as chemical factories, who has sniffed with disgust a chemical odor, has been urged to believe that the chemist's shadow contaminates pure foods, and has been taught in school that alchemy spelled fraud and sorcery, our science is one calculated to develop the ideal side of human nature, and the chemist, more perhaps than the votary of natural science or the devotee of the so-called humanities, is led to an intense interest in human development. . . ."

Page 129: "... Our science aspires not only to know, but also to do. On the one hand, it leads us to delve into the secrets of nature, in the minute atom as well as in the far distant stars, in the living cell as well as in the crystallized relics of the convulsions from which this earth was born; on the other, it leads us to apply this knowledge to the immediate needs of man, be it in safeguarding his health, in ministering to his material or esthetic wants, or in regulating his commerce and in facilitating his utilization of the earth's resources. . . ."

"... There are two ways of aiding a man or a cause: by addition to the income or reduction of the expense. The pecuniary result to the beneficiary may be the same, but the moral one is far different; it is not only the beggar who is pauperized by the cash gift and uplifted by the aid which enables him to earn

his own livelihood. Arts and sciences may be stimulated by prizes and scholarships beyond a doubt, but the relation between donor and recipient is not free from restraint and the probability of human error in the selection of the right incumbent makes the method a wasteful one at best. . . ."

Part I. contains also his lectures on the "Fundamental Ideas of Physical Chemistry," "Osmotic Pressure," "Electrolytic Dissociation," "Atoms and Molecules," "Hypothesis of Radiant Matter," all models of clear exposition of difficult subjects.

The 170 pages of the second part of the volume relate exclusively to original experimental investigations carried out by Morris Loeb since 1885. His latest contribution "Studies in the Speed of Reductions" was read by him at the International Congress of Chemistry in 1912, a few days before his untimely death, which took him away in the prime of life, from his family and his many friends.

L. H. BAEKELAND

YONKERS, N. Y.

Curious Lore of Precious Stones. By GEORGE FREDERICK KUNZ. Philadelphia and London, J. B. Lippincott Company. 1913. Pp. xiv + 406. Six color plates, 22 double tones and 24 line cuts.

The object of this book, as stated in the preface, is to "indicate and illustrate the various ways in which precious stones have been used at different times and among different peoples, and more especially to explain some of the curious ideas and fancies which have gathered around them. Many of these ideas may seem strange to us now, and yet when we analyze them we find they have their roots either in some intrinsic quality of the stones or else in an instinctive appreciation of their symbolic significance. Through manifold transformations this symbolism has persisted to the present day."

To the interesting task thus outlined Dr. Kunz has brought a lifelong familiarity with gems, knowledge gained by the formation of several collections illustrating the folk-lore of precious stones and the possession of what is

on this subject probably the most comprehensive library in the world. That Dr. Kunz treats the subject sympathetically is to be expected; that he will lead others to similarly regard it is a probable and desirable result of his book. Whoever thinks that superstition is dead among civilized peoples and that only in an age of darkness could a belief in the powers of such insensate bits of matter as gems gain credence, should read the chapter on "Ominous and Luminous Stones" and learn how the innocent and charming opal, regarded entirely without prejudice in the sixteenth century, came, in the nineteenth century, to be invested with fear and dread. All jewelers know that the superstition regarding the opal at the present day seriously interferes with its sale even among the most enlightened. Dr. Kunz evidently would not desire to perpetuate superstitions regarding precious stones, but that they should be invested with sentiment he approves. Thus in the chapter in birthstones (a subject which he treats exhaustively) he says:

"Sentiment, true sentiment, is one of the best things in human nature. While if darkened by fear it may lead to pessimism, with all the evils which such a state of mind implies, if illumined by hope it gives to humanity a brighter forecast of the future, an optimism that helps people over difficult passages in their lives. Thus, sentiment must not be neglected, and nothing is more likely to destroy it than the conviction that it is being constantly exploited for purposes of commercialism. For this reason, the interest as well as the inclination of all who are concerned in this question of birthstones should induce a very careful handling of the subject."

And again,

"Sentiment may best be expressed as the feeling of one who, on a warm summer's day, is rowing along a shady brook or resting in some sylvan dell, with nothing to interfere with his tranquil mood and nothing to spur him on to action; thus he has only suggestions of hope and indulges in rosy views of life. Reality, on the other hand, may be likened to

a crisp winter's morning when one is filled with exhilaration, conscious of the tingle of the cold, but comfortable in the knowledge of wearing a tightly buttoned garment which will afford protection should the elements become disturbing. Superstition, lastly, may be said to resemble a dark, cold, misty night, when the moon is throwing malevolent shadows which are weird and distorted, while the cold seems to seize one by the throat and arouse a passionate desire to free one's self from its grip in some way, to change a horrible nightmare into a pleasant dream."

It is probable that it is in the explanations which he gives of the causes of the "curious ideas and fancies" which have gathered around precious stones that Dr. Kunz makes his most important contribution to the subject of his book. So far as the present writer is aware, this has never been attempted before so carefully, or at least with so keen a sense of the mutual relations of the various factors involved. Thus the results of crystal gazing are shown to be due to hypnotism; fancy for birthstones to tradition; the powers of colored stones to color effects, and so on. Besides those already mentioned, some of the subdivisions of the subject treated are, "Talismans and Amulets," "Engraved and Carved Gems" and "The Therapeutic Use of Precious Stones."

As a compendium of the virtues and powers ascribed to precious stones, this work is probably not entirely exhaustive, but it is not meant by this statement to imply that the book is not comprehensive. An exhaustive catalogue of the various attributes of precious stones would probably lack the readableness with which Dr. Kunz has succeeded in investing his work in a remarkable degree. In typography and illustrations the book exhibits the sumptuousness which has always marked Dr. Kunz's works. Some further indication than is given of the size of the objects represented in the plates might be desirable and one could wish more of the jewels to have been represented in color. These are, however, but slight shortcomings in a book which can hardly fail in any part

to interest the student of precious stones and of mind.

OLIVER C. FARRINGTON

The Anarchist Ideal and Other Essays. By R. M. WENLEY.

This contribution of Professor Wenley's must be accepted as it is offered, as a record of varied interests. The topics considered, which in part appeal to the man of science, are various. The essay which gives the name to the volume is entirely retrospective in its view and supplies a parallel in Greek life for the independence of thought and the revolt from established conventions, of which theoretical position the anarchist is a practical and an extreme expression; it is a study of the intellectual sources of the anarchist position. Its value consists in broadening the historical aspect of movements which in their modern setting are overshadowed by local situations. Similarly retrospective is the essay upon "Plutarch and His Age." The central position in the volume is given to a review of the early movement towards physiological psychology. This is an able presentation of the philosophical positions which preceded and guided the formation of psychology as a scientific pursuit. The complex origins are traceable primarily to German philosophers as well as to such men as Weber, Fechner, Lotze, Helmholtz and Wundt, whose philosophical interest was joined to their more rigidly scientific investigations. It is Professor Wenley's purpose to supply not a narrative of the contributions of these men, but rather an interpretation of the intellectual movement which guided them towards the consummation to which they severally but differently contributed. On the whole the two educational essays, the one on "Heredity and Education" and the other on the "University in the United States," give ampler opportunity for Professor Wenley's individuality of thought and for the display of the temper of his opinions. By long residence a member of the professorial guild in this country, yet by training and tradition equally at home in the intellectual perspective of English and Scot-

tish universities, he is in a peculiarly favorable position to perform the functions of comparative criticism which he judiciously exercises. Considerate alike of the inevitable shortcomings of educational provisions in the pioneering stage and of the success which has attended them, he retains the fundamental critical attitude in view of old-world standards; he retains also the rare gift of seeing things as they are, despite the enveloping fog which optimism so commonly breeds. The chief note of his complaint is the neglect of individuality and the lack of professional opportunity within academic life for the man of parts, whose development does not conform to the conventional channels of preferment. In a like sympathetic spirit he attempts to portray for English readers some of the peculiar problems which beset American universities, and does so with remarkable success. From beginning to end the volume is characterized by a directness of statement and an insight into relations which gives the whole a higher value than the seemingly casual treatment suggests.

JOSEPH JASTROW

THE PHYLOGENETIC RELATIONSHIPS OF THE OYSTERS

DR. JAWORSKI, of Bonn, has given in the "Zeitschrift für Induktive Abstammungs- und Vererbungslehre" an interesting discussion of the phylogenetic relationships of the oysters. The material upon which he bases his new *Ostrea* genealogy was collected in the middle Jurassic (Dogger) of northern Peru.

Jaworski's theory is based on the discovery of a new ostreid in the Peruvian Jurassic of considerable dimensions—approximately those of a large *Ostrea virginica*, though much more massive—characterized by (1) incurved and strongly gyrate umbones (those of *Ostrea sensu stricto* are approximately straight); (2) by a broad and greatly elevated hinge area (that of *Ostrea* is moderately low, and either broad or narrow); (3) by a ligament partly internal and partly external, located in large measure behind the beaks and produced beyond the hinge area proper (that of *Ostrea* is wholly

internal, medial in position, and confined strictly within the hinge area); (4) by the presence of an anterior adductor muscle impression indicating the persistence of the anterior adductor in the adult stage (in *Ostrea*, the anterior muscle has been observed by a number of embryologists in larval forms though never in stages later than the nepionic); (5) by the presence of pedal impressions indicating a well-defined, though probably reduced foot (in *Ostrea*, the locomotor organ is the velum which persists throughout the free swimming stage, and the presence of a well-defined foot and byssus have never been established even in the embryo).

These observations have led Jaworski to the theory that the new form, the *Heterostrea steinmanni* Jaworski, represents the mid-Jurassic ancestral type from which the true oysters of the Cretaceous, Tertiary, and Recent were directly derived. In order to establish this new hypothesis, it is necessary to first overthrow some of the critical work that has already been done along this line and from which quite different conclusions have been drawn. The three most notable researches are those made by Jackson, of Harvard, Douvillé, of the French Geological Survey, and Steinmann, of Bonn. Jackson's work was done at the Museum of Comparative Zoology, and his approach to the problem was by way of the embryology of the oyster and a number of closely related mono- and heteromyarian groups. The oysters were watched through all stages of development of the egg, the spat encouraged to attach themselves to transparent media and the growth phenomena studied under magnification. He was thus able to confirm and elaborate many of the observations of Huxley, Horst and Brooks, notably those on the number and position of the adductor muscles during the earlier development of the form.

Ostrea, like all other pelecypods in which the embryonic development has been carefully worked out, passes through a monomyarian stage in which, curiously enough, the single adductor muscle is anterior in position, although it is not the antecedent of the anterior

adductor of the adult. Then there is a short period at the end of the prodissoconch and the beginning of the dissoconch stages in which both the anterior and posterior adductors are present and typically dimyarian in position. About the third day after the animal has become attached, the anterior adductor evanesces, and only the posterior remains. The atrophy of the anterior adductor has been explained by purely mechanical action: in the dimyarian stage, the orientation of the soft parts is similar to that of the typical pelecypod; the mouth is approximately midway between the hinge line and the ventral margin and the antero-posterior axis is approximately parallel to the hinge; as soon as the spat become fixed, there is a shifting of this axis through almost 45 degrees so that the mouth lies close up under the hinge. This change in position brings the anterior adductor so near the hinge that it loses most of its efficiency; there is, therefore, a compensating increase in the size and effectiveness of the posterior adductor which is gradually shifted to a point of vantage near the central portion of the valves.

The character and mode of development of the soft parts, as a whole, have led Jackson to the belief that *Ostrea* is the sessile analogue and the direct descendant of the free swimming *Perna*. The difference in habit would readily explain the unequal valves and the absence of the foot in the one form and the equal valves and well-developed foot in the other. *Perna* is characterized, however, by a series of vertical cartilage grooves while in typical *Ostrea* there is a single trigonal sub-umbonal pit. Jaworski's criticism of Dr. Jackson's theory of the relationships seems pertinent: the very fact that the young of *Perna* possess a single sub-umbonal pit similar to that of *Ostrea* and the adults a series of pits implies a highly specialized type. The similarity of the young of *Ostrea* and *Perna* may very properly be due to descendance along collateral lines from a common aviculoid ancestor, but there is small evidence of any more direct relationship. Jackson considers *Exogyra* and *Gryphæa* derivative forms of *Ostrea* which have become highly modified.

Douvillé, like Jackson, considers the oysters as direct descendants of true aviculoids not from *Perna*, however, but from *Lima*. The sessile aviculoids are cemented, as a rule, by the right valve, while in the oysters it is the left valve that is attached. However, it is probable that Douvillé overvalues the systematic importance of this character, for in the inequivalved Pectens it is sometimes the right valve and sometimes the left which is the more convex. *Lima*, a significant fact to Douvillé, assumes an almost vertical position as indicated by the approximately equal valves and the presence in both of a byssal opening. Furthermore, the characters of the ligament are similar in the Ostreids and the Limas. The *Ostrea*, however, does not apparently attach itself by a byssus at any stage in its development. Jackson watched very carefully for such a phenomenon, but was unable to find any trace of it. On the contrary, the spat appear to attach themselves at the very beginning of cementation by the margin of the reflected mantle. If the Ostreids were the direct descendants of *Lima*, as Douvillé believes, they would probably reveal to a skilled embryologist such as Jackson some clue to the presence of a former attachment.

Two major groups of Ostreids have been established by Douvillé: in the one, he has assembled all the dominantly smooth forms, in the other, all the dominantly plicate. In both groups, he finds forms with straight umbones and those with gyrate beaks, and the outline of the species is, in his opinion, directly associated with the environment. Thus, the straight-beaked *Pycnodonta* is characteristic of deep and quiet waters, while forms with strongly twisted umbones, such as *Exogyra*, are developed in the more shallow waters, where there are strong currents to be resisted. If this theory be accepted, it is difficult to account for the frequent association of *Pycnodonta* and *Exogyra* in considerable numbers in the same marl bank. In his correlation also of the sculpture of the plicate group with their environment, his theories seem unwarranted by the facts. It is true, to be sure, that, as a rule, the right valve of the Ostreids

is less vigorously sculptured than the left, but there is no evidence that the sculpture evanesces more rapidly in the littoral forms. On the contrary, a strong ribbing is most frequently developed where the need for resistance is greatest.

Douvillé as well as Jackson considers the *Gryphaeas*, *Pycnodontas* and *Exogyras* as derivatives of the true oysters. Jaworski does not admit, however, that the Ostreids of the Triassic which have served as the theoretical ancestral types are true oysters. Steinmann traces the ancestors of the group even back of the Mesozoic and considers *Eurydesma* of the Permo-Carboniferous of Australia and India as the true ancestor of the Ostreid stock. This form is characterized by a heavy, lamellar shell, prosogyrate beaks, a marginal, posteriorly produced ligament, and possibly an incipient dentition. The most significant feature, namely, the character of the muscle impressions, is doubtful: the form has been commonly accepted until recently as monomyarian. Morris, however, observes "there is one large impression posteriorly and perhaps a small one anteriorly." If the presence of an anterior as well as a posterior scar can be established, *Eurydesma* would, in the opinion of Jaworski, fall in line behind *Heterostrea*; if its absence can be proved, *Eurydesma* should be considered as the ancestral form of the *Gryphaeas* and *Exogyras*. It is *Heterostrea steinmanni* Jaworski which its describer considers the true ancestor of the true oyster.

The line of development between the two forms is, in his opinion, well defined, and easy to follow: the degree of coiling of the umbones is functional upon the ratio of the size of the left valve to the adhering surface; the larger the area of cementation, the stronger the tendency toward an elongate outline and straightened umbones; with the change in the direction of the beaks, there is a corresponding shift of the ligament from its original position along the posterior margin to a more effective point of attachment directly beneath the tips of the umbones. The obsolescence of the anterior adductor is doubtless the result of the shift of the antero-posterior axis consequent

upon the readjustment of the soft parts of the animal.

Jaworski evolves and develops another theory of phylogenetic relationship which seems so untenable that it may be disregarded—namely that the strongly plicated oysters such as the *Ostrea edulis* are the descendants of the strongly plicate *Gryphæas* of the Mesozoic. The surface sculpture is not a fundamental character among the oysters and there is no reason to search for its cause in distant ancestral relationships. Regarding the phylogenetic significance of *Heterostrea steinmanni* it would seem that it was an entirely too specialized form to have given rise to the subsequent *Ostrea* stock.

THE CHEMICAL DYNAMICS OF LIVING PROTOPLASM

VAN'T HOFF's formulation of the laws of chemical dynamics has proved so stimulating to various fields of chemistry that it may be expected to be similarly useful if it can be applied to the activities of living protoplasm.

The writer finds that by measuring the electrical resistance of living tissues it is possible to follow the progress of reactions in protoplasm in the same way that van't Hoff followed the progress of reactions *in vitro*. It therefore becomes possible to apply van't Hoff's methods and formulæ directly to protoplasm in its living and active condition. The following example will suffice to show how this may be accomplished.

The electrical resistance of living tissue of the marine alga *Laminaria* was measured by a method which has been previously described.¹ The tissue had in sea-water a resistance of 980 ohms.² On being placed in NaCl .52M (which had the same conductivity as sea-water) the resistance fell after 10 minutes to 855 ohms and after 20 minutes to 745 ohms: it continued to fall rapidly and finally became

¹ SCIENCE, N. S., 35: 112, 1912.

² If left in sea-water this resistance is maintained for a long time.

stationary at 320 ohms. This represents the death point. The total change produced by the NaCl was $980-320=660$ ohms.³ In order to find out whether this change had been produced in such a way as to correspond to a known type of chemical reaction the amount of change was measured at brief intervals. The results are given in Table I.

TABLE I

t —time in Minutes	Resistance	x —loss of Resistance	$a-x$	$\frac{a}{a-x}$	$\log_{10} \frac{a}{a-x}$	$k = \frac{1}{t} \times \log_{10} \frac{a}{a-x}$

300	320	660	0			Average

a = total change = $980-320=660$ ohms.

Temperature 18.5° C.

According to van't Hoff we can determine from such measurements whether one, two or more substances are taking part in the reaction. If only one substance takes part (or if two substances take part but only one of them changes its concentration noticeably) the reaction is said to be of the first order (monomolecular) and it proceeds according to the formula

$$k = \frac{1}{t} \log \frac{a}{a-x},$$

in which t is the time which has elapsed between the beginning of the reaction and the taking of the measurements, x is the loss in

³ The fact that this action of NaCl may be antagonized by CaCl_2 does not affect the subsequent discussion.

resistance at the time t , a is the total amount of change in resistance when the reaction is completed and k is a constant (called the velocity constant) which indicates the speed of the reaction. If the reaction is of the first order (monomolecular) k should come out constant provided the temperature be kept constant during the reaction.

In this case a , which represents the total amount of change, is $980 - 320 = 660$ ohms, while x represents the loss of resistance after 10, 20, 30 minutes, etc. In the calculations common logarithms have been employed. It will be seen from the table that k is nearly constant: the variations are no greater than are commonly found in measuring chemical reactions in the test tube.⁴ It is probable that they would have been smaller if the temperature could have been kept perfectly constant.

The simplest interpretations of this are as follows. We may suppose that the NaCl reacts with some one substance in the protoplasm but that so little of the NaCl is used up that its concentration changes but slightly.⁵ It can be shown by analytical methods that the concentration of the NaCl suffers but little change. In all of the experiments more than 1,200 c.c. of NaCl .52*M* were employed to 10 c.c. of tissue.

It should be added that if a series of reactions is involved what we measure is practically the rate of the slowest of the series.

⁴ The most constant value of k is obtained when the material is sound and is taken directly from the ocean just before the beginning of the experiment. The temperature should not be allowed to rise much above that at which the plants have been growing. The fronds should be neither too old nor too young, and should not have reproductive organs. Fronds should be selected which have the mechanical properties requisite to cause the disks to lie flat in the apparatus when it is closed, but to separate spontaneously when it is opened. Failure to realize these conditions, as well as other imperfections in technique, may produce irregular fluctuations in the value of k .

⁵ This applies as well if we suppose that the NaCl in uniting displaces some other substance (e. g., CaCl_2) provided the latter is not allowed to accumulate too much in the solution.

An alternative interpretation is that the loss of resistance is due to the spontaneous change of some one substance in the protoplasm, a process which goes on with extreme slowness until catalyzed by the NaCl. This view is of great interest because it implies that the process of death is always going on even in a healthy and growing cell.

If we suppose the NaCl to act as a catalyzer it may be that the reaction which it accelerates is the hydrolysis of some substance in the protoplasm. This would behave as a reaction of the first order since the concentration of neither the NaCl nor the water would undergo much alteration. The reaction might be compared to the hydrolysis of cane sugar (when catalyzed by acid) which behaves as a reaction of the first order.

On this view death would be due to the hydrolysis of some substance (probably protein) in the protoplasm. There is a variety of evidence that death is accompanied by such hydrolysis.

We should not overlook the possibility that the opposite process (dehydration) would give quite the same result. Death is often accompanied by the coagulation of certain proteins. According to some authors coagulation involves dehydration while according to others it is a process of hydrolysis.⁶

We may now consider other possible suggestions. One is that the progress of the reaction is determined not by the number of substances taking part but by diffusion. The NaCl⁶ diffuses inward (and the other salts outward) rapidly at first, then more and more slowly, thus affording a certain likeness to the curve of a reaction of the first order. The incorrectness of this interpretation is shown by a study of the temperature coefficient. The temperature coefficient of diffusion is low, the increase in the rate of diffusion being less than 30 per cent. for an increase of 10° C. The increase in the velocity of the reaction of NaCl with living protoplasm amounts to over 150 per cent. for an increase of 10° C., which

⁶ The addition or splitting off of H ions would also behave as a reaction of the first order.

shows clearly that we are dealing with a chemical reaction. We must, therefore, exclude the interpretation that diffusion is the determining factor.⁷

Another suggestion is that the result is due merely to the fact that the majority of the cells are more accessible to the reagent or less resistant to it than the rest, so that more cells are killed in the first minute than in the second and so on. But if this were the case we could not, after a lapse of ten minutes (when the loss of resistance already amounts to 125 ohms), restore the tissue to its initial resistance by replacing it in sea-water. This can be done and there is no evidence that the tissue is in any way injured by such treatment with NaCl.⁸ The same piece of tissue may be treated with NaCl (for five minutes) and replaced in sea-water several times each day for ten days in succession without showing any sign of injury.⁹

This leads us to the following conclusion. Since the effect of NaCl is within wide limits completely reversible, without production of injury, *the conception of the chemical dynamics of living protoplasm here developed applies not only to reactions which produce death but also to reactions which involve no injury and which form a normal part of the activity of the cell.* This conclusion is fully confirmed

⁷ There are other important reasons opposed to the suggestion that diffusion is the determining factor. One of these is the length of time required for the process. If tissue is transferred from sea-water to sea-water diluted with one or two volumes of distilled water, there is a change of resistance which continues until equilibrium has been restored by diffusion. This process at 18° C. does not take more than ten minutes, whereas nearly three hours would be required for the reaction with NaCl which we have been measuring.

⁸ This and other experiments show that the increase in the conductivity of the protoplasm is not to be attributed to an increase in the concentration of electrolytes within the cell but rather to a decrease in the viscosity of the protoplasm (or to an increase in some other factor which facilitates the passage of ions).

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION H—ANTHROPOLOGY AND PSYCHOLOGY

At the recent annual meeting of the American Association for the Advancement of Science held at Atlanta, Georgia, December 29 to January 2, Section H—Anthropology and Psychology—participated in four sessions. Tuesday afternoon was devoted to a "general interest" session at which Professors Max Meyer and Lightner Witmer spoke. Wednesday morning was given over to a joint meeting with the Southern Society for Philosophy and Psychology; Thursday morning to a joint session with Section L—Education, and Thursday afternoon to a joint session of all three of these organizations. In all some twenty-two papers were presented.

The following officers were elected: *Vice-president of the Association and Chairman of the Section*, Dr. Clark Wissler, of the American Museum of Natural History; *Member of the Sectional Committee* (to succeed Dr. G. A. Dorsey), Professor Lightner Witmer, of the University of Pennsylvania; *Member of the Council*, Professor Max Meyer, of the University of Missouri; *Member of the General Committee*, Professor L. R. Geissler, of the University of Georgia.

The following twelve papers were presented under the auspices of Section H:

The Present Problems of Physiological Psychology: MAX MEYER.

Psychologists generally are beginning to realize that the study of consciousness is only a secondary, an auxiliary branch of psychology. But it is a mistake to think that psychology can be defined simply as the study of behavior. The study of plant behavior is the business of the botanist. Nothing forbids, of course, interest in plant behavior on the part of the psychologist save common sense, which would call a man a botanist if he is more interested in plant behavior than in human life. In a similar way the study of animal behavior must be regarded as primarily the task of the zoologist. And the study of human behavior seems to be largely the province of the sociologist (including under "sociology" as a special branch the science of education). Is then

nothing left for the psychologist as his proper field? My answer is that it is the psychologist's business to make comprehensible that link which is interposed between our sensory surfaces and our muscles, the function of the nervous system. Apparently, this demand is supplied by a scientist who, again, is not the psychologist—by the physiologist. As a matter of fact, however, a text-book on the physiology of the nervous system, even such as Sherrington's or Loeb's, would not suit the needs of a college class in psychology. I should say, therefore, that the psychologist's task consists in making comprehensible the function of the nervous system as the chief determiner of all those varied forms of human behavior which we find described in a good novel, in the drama, in biography, in history, in the newspaper. In order to illustrate this task, a number of typical problems were discussed and solutions proposed.

Children with Mental Defects Distinguished from Mentally Defective Children: LIGHTNER WITMER.

"Were society so organized that success in life in every sphere of activity were dependent upon a good enough ear to turn a tune, many persons who are now doing useful work in the world would have to be relegated to the class of imbeciles." Several cases were reported, among them the case of a boy who at fourteen years, although he was normal in appearance and behavior and had been attending school regularly, was at the educational stage of a child of seven. He was unable to read for himself, for pleasure or profit, and his spelling was as deficient as his reading. When he wrote a letter it was impossible to make out his meaning without knowing what he had intended to say. Careful examination showed that the boy was suffering from a language defect, psychologically a defect of memory. There was both a weakness in retaining new impressions and a weakness in the recall of impressions which had been received and partially retained. He was word deaf as well as word blind, or, to put it scientifically, he was a case of congenital aphasia. "Congenital aphasia is a more serious defect to the individual than the lack of an ear for music, because of the social and industrial importance of speech; perhaps also because a certain measure of language development is essential for accurate thinking. . . . I regard the child, for that matter the adult also, as composed of a number of traits, some of them assets if they favor normal mental development and success in adult life; some of them defects if they provoke retardation, arrested

development, delinquency and crime. There is no so-called normal person who does not possess some defects along with his assets. The type of child in whom I am especially interested and for whom I organized and am directing the work of the psychological clinic at the University of Pennsylvania, is the child who has so many and such severe mental defects as seriously to interfere with normal development in the home and in the school and to prognosticate his arrival at adult age arrested in mental and moral development. Because a child has one or a few mental defects, we must not characterize him as mentally defective. . . . A strictly scientific nomenclature will dispense with the term 'mentally defective,' as failing to characterize with sufficient definiteness the class of children under consideration. What characterizes 'mentally defective' children is not that they are mentally defective, for other children, in fact all children, are mentally defective, but that they are so defective mentally as to be socially unfit. For the term 'mentally defective' I would therefore propose substituting the term 'socially unfit' or 'socially defective.' "

Published in *The Psychological Clinic*, Vol. VII., No. 7, December 15, 1913.

Some Fundamental Concepts in Social Psychology: L. R. GEISSLER. (By title.)

Correlation of Mental and Physical Measurement: JASPER C. BARNES.

The correlations described in this paper are based upon the physical measurements of one hundred students, members of the psychology class in Maryville College, during the year of 1912-13 and the fall term of 1913. The list includes fifty young men and fifty young women representing all of the four college classes and twenty different states. The average age of the young men was 21.7 years, while the average age of the young ladies was 21.3 years. The youngest in each case was 17. The oldest young man was 26, and of the young ladies 31. The mental measurements are in terms of grades received by the students in their various studies, and hence are not mental measurements in the laboratory sense at all. The physical measurements were five: height, weight, vital capacity, length and width of head. The apparatus used was the stadiometer, anthropometric scales, wet-spirometer and head calipers.

According to the method of group comparison there seems to be very little relation between height and scholarship, or weight and scholarship. But between the vital capacity and mental abil-

ity there appears to be some correlation by the method of comparison, yet when computed by Pearson method the index of correlation is very small. The coefficients of correlation calculated by the Pearson method are as follows:

	Men	Women
Weight and class standing.....	.056	.052
Height and class standing.....	.023	.216
Vital capacity and class stdg....	.085	.245
Cephalic index and class stdg....	-.033	-.151

In summing up the foregoing, it appears that the measurements in this series have little interdependence.

The index of correlation except in the case of the vital capacity of women, is a negligible quantity. However, the number of cases is too small in our investigation to justify the statement of any general conclusion or law. It may be said, nevertheless, in the hundred cases studied, there seems to be little, if any, correlation between mental ability, as shown by class standing of college students, and height, weight, lung capacity and cephalic index.

The Causes of the Declining Birth-rate: J. McKEEN CATTELL.

The completed family of contemporary scientific men is about 2, the surviving family about 1.8 and the number of surviving children for each scientific man about 1.6. Twenty-two per cent. of the families are childless; only one family in seventy-five is larger than six. The same conditions obtain for other college graduates. The speaker discussed the biological causes through which the fertility of a woman has been limited to an average of about twelve children, the social causes which lead about one half of all women of child-bearing age to remain unmarried, and the pathological and psychological causes which give the present family of two or three children. Answers had been received from 461 leading scientific men giving the causes which led to the limitation in the size of their families. One hundred and seventy-six were not voluntarily limited, while 285 were so limited, the cause of the voluntary limitation being health in 133 cases, expense in 98 cases and various other reasons in 54 cases. Childlessness was involuntary in two thirds of the cases. In the standardized family of two the condition is desired in six cases out of seven. In over one third of the families the limitation was involuntary, due to infertility and other pathological causes, but if these had not obtained, voluntary

limitation would have occurred in nearly all or perhaps in all cases.

On the Effect of Adaptation on the Temperature Difference Limen: EDWINA ABBOTT.

The effect of adaptation to different temperatures on the difference limen for 40° C., 37.5° C., 35° C., 32.5° C., 30° C., 27.5° C., 25° C., 22.5° C., 20° C. and 17.5° C. was determined. Water was used as the adaptation medium and was kept at any desired temperature by means of an electric heater controlled by an electric thermostat. The fingers of both hands of the subject were adapted to a certain temperature as far as the second joint and when adaptation was complete the fingers were raised and those of one hand dipped into water of the standard temperature and those of the other hand into water of the variable temperature for the difference limen test. The method of right and wrong cases was used in determining the limen and the fingers readapted before each test. Four trained subjects were used.

The results indicate that: (1) The difference limen for a given temperature after a given adaptation temperature is relatively constant for a given individual; (2) the absolute amount of the difference limen under such circumstances differs for individuals, but the relation between the limina for different temperatures after any given adaptation temperature remains the same for different individuals; (3) the point of greatest sensitivity to difference lies at 32.5° C.; (4) the preceding adaptation temperature affects the difference limen for a given temperature, the difference limen, in general, increasing as the adaptation temperature varies from the standard temperature; except for 32.5° C. where the difference limen remains constant under all conditions of adaptation.

Eventually to appear in the *Psychological Review*, Monograph Series.

A Study of the Behavior of the Chick: ADA HART ARLITT.

In February of 1913 work suggested by that of Féré on the effect of alcohol on the physiological development of the chick was undertaken in the biological laboratory of Newcomb College. It was found possible to raise healthy chicks from eggs which had been subjected to alcoholic treatment, but the behavior of these chicks differed from that of normal chicks hatched in the same incubator at the same time.

The reactions to light and the pecking and drinking reactions of the abnormal chicks differed but little from those of normal chicks.

Abnormal and normal chicks were placed on stands from 10.7 cm. to 179 cm. above the box in which they were kept and the height at which they refused to jump recorded. The abnormal chicks jumped from greater heights.

To determine the difference in rapidity of learning three mazes were used, one a straight path blind at one end, one a simple choice maze with the exit on the left side, the third the Yerkes apparatus.

The chicks were given ten trials each in each of the first two mazes and the time taken to find the exit recorded. Abnormal chicks learned their way out of the first maze almost as swiftly as normal chicks, but learned their way out of the second much more slowly, making many wrong choices. Two failed to learn the way out.

With the Yerkes maze the number of trials taken before the chick made ten consecutive right choices was recorded. The exit was on the right side. The normal chicks learned the way to the exit in 8 trials, the abnormal in from 23 to 45 trials.

Two Factors which Influence Economical Learning: EDWARD K. STRONG, JR.

The paper presented the results of a number of experiments in the field of advertising and discussed their bearing upon studies that have been made in the field of economical learning.

The general conclusions were as follows: (1) Repetitions of advertisements a few minutes apart or a week apart are about equal in efficiency when tested four months later, but both such intervals are superior to repetitions a month apart. On the basis of all the work in this field, it would seem that the optimum interval for repetition is one day. (2) The more impressions made at one time, the less is the permanent retention of any one of them. This is probably due to the effect of retroactive inhibition. (3) In any situation when both length of interval and the number of impressions to be made at any one time are concerned, it should be borne in mind that the second factor is far more important than the first. This means that further work should be directed more particularly to a better understanding of how many impressions can be made to advantage at any one time, rather than to the proper interval of time between their successive presentations.

Psychological Characteristics of the African Negro: JEROME DOWD.

Professor Dowd divided Africa into economic zones, and contrasted the characteristics of the people of each zone.

"The instinct of flight is very pronounced in the banana zone. Nature is here manifested in a very violent form—exciting terror and gross superstitions. It is a zone of idols, fetishism, witchcraft and the magic-doctor. In the agricultural zones nature is less antagonistic, and the struggle for existence more severe, requiring more reason and courage. Here the emotion of fear is less pronounced—the number of idols diminishes, and the magic-doctor uses less *hoocus pocus* and more medical art. In the cattle zone, where nature is still less violent and terrifying and the climate and other conditions more conducive to action, we observe still less fear among the people, less use of idols, witchcraft and magic-doctors.

"The instinct of pugnacity is weak in the banana zone because of the intensity of the feeling of fear. It is more pronounced in the agricultural zones, and very much so in the pastoral zones where the conditions provoke chronic warfare. This instinct is of great value to any race—since, under peaceful conditions, it is carried over into all lines of activity. Instead of the war of fire and sword, we have the war of tools, machinery, commodities and ideas. From the games played by children and adults up to the rivalry of nations for intellectual and moral supremacy we see the play of this primitive instinct. The nations that now occupy the highest rank in the industrial rank in intellectual and moral development are precisely those which have gone through the fiercest and most prolonged era of warfare.

"The gregarious instinct is remarkably developed in the central regions of Africa where the bounty of nature permits of the living together of large groups. It is not quite so well developed in the other zones, although it is everywhere very characteristic of the African Negro. In the lower stages of society this instinct serves the useful purpose of insuring to aggregations of people the development of laws and institutions. McDougall believes that this instinct is less important for civilized people and often produces anomalous and even injurious social consequences in large cities. According to Giddings and McDougall, this instinct is due to consciousness of kind. I believe, however, that people are attracted to each other by unlikeness, and the so-called instinct of gre-

garioussness is nothing but the expression of the instincts of fear and curiosity."

Reason, imagination, inhibition and other characteristics were discussed.

A Comparison of White and Colored Children Measured by the Binet Scale of Intelligence:
JOSIAH MORSE.

Two hundred and twenty-five white and one hundred and twenty-five colored children in the public schools of Columbia, S. C., were tested; ages ranging from six to twelve, inclusive. Results: The number of white children testing at age is decidedly larger than any other group, whereas for the colored children the largest group is the one testing one year below age. In the satisfactory group there is a difference of nearly 15 per cent. between the white and colored; nearly three times as many colored are more than a year backward, and less than one per cent. are more than a year advanced.

The picture tests, those relating to time and money, distinguishing between morning and afternoon, enumerating the months, counting stamps and making change, the drawing tests, both copying and reproducing from memory, were all too difficult. The answers to the questions of comprehension, to the absurd statements and to the problems of various facts, were often absurd or senseless; the best replies, however, compare favorably with those of the white children. The definitions were often not better than terms of use, and frequently stated in the language of a younger child.

Compared with the white, the colored children excelled in rote memory, *e. g.*, in counting, repeating digits—though not one was able to repeat 26 syllables—naming words, making rhymes, and in time orientation. They are inferior in esthetic judgment, observation, reasoning, motor control, logical memory, use of words, resistance to suggestion, and in orientation or adjustment to the institutions and complexities of civilized society.

A rough classification into three groups, according to color—dark, medium, light—showed that the darkest children are more nearly normal, the lightest show the greatest variation, both above and below normal.

The paper appeared in the January number of *Popular Science Monthly*, Vol. LXXXIV, No. 1, January, 1914.

A General Intelligence Test: L. R. GEISSLER.

Minor Studies in Learning and Relearning: DAVID SPENCE HILL.

The studies presented were from the standpoint of an instructor in educational psychology for college classes, and illustrate useful methods of individual and class experimentation. The studies consist of three series. The first is descriptive of material for and uses of mirror-drawing. One subject practised drawing stars for forty-eight days. Three years afterward the trials were resumed, and it was found that in about three trials the former speed and accuracy were attained. Analysis of the relearning does not show evidence that "the mind continues its activity for a time in the furtherance of a learning process after practise and study have ceased," as suggested in the similar experiment of Swift.

In the mirror-drawing experiment, by initial and terminal tests before and after the above practise, an interesting demonstration was made of the regulation of transfer effect, both to right and left hands. This was accomplished by the use of slightly dissimilar geometrical figures, by the use of which there were found fairly consistent differences in net results of improvement.

The second study is a class experiment employing substitution tests. A group of ten students participated during twelve days. A presentation of the problems of intervals of study, the method of equal groups, the question of individual differences before, during, and after practise is included.

The third series consisted of cancellation experiments the object of which was to illustrate a convenient form of A-test suitable for group or individual use. In constructing the form, twenty-six marbles were marked with the letters of the alphabet, shaken in a small basket and thereupon a marble was withdrawn. After the letter was written down another mixing and withdrawal was made, and finally the MS. thus constructed was printed by a linotype. This method of distributing the twenty-six letters, although laborious, secured for practical purposes one hundred alphabets arranged in chance order. A group test during fourteen days was made upon the effect of practise in making A's and concerning the transfer of the improved capacity to marking words containing e and r, from a Latin text. The results are not inconsistent with those of Thorndike.

The paper will appear in the *Journal of Educational Psychology*.

NEW EDITION OF THORPE'S DICTIONARY OF CHEMISTRY

Now Complete In Five Volumes

A DICTIONARY OF APPLIED CHEMISTRY

By Sir EDWARD THORPE, C.B., LL.D., F.R.S., Emeritus-Professor of Chemistry, Imperial College of Science and Technology, South Kensington, London, etc. Assisted by eminent contributors. Revised and Enlarged Edition in 5 Vols. With Illustrations. Royal 8vo. Vol. I. A—Che; Vol. II. Chi—Go; Vol. III. Gr—Oils; Vol. IV. Oilstone—Soda Nitre; Vol. V. Sodium—Z. \$67.50 net. Separately, each volume, \$13.50 net (Postage Extra).

"The revision and publication of these volumes has been a great undertaking and it is gratifying to find that both the editor's work and the mechanical production have been accomplished with such promptness and success. In its present revised form, it is doubtless the most comprehensive and complete book of reference now in existence covering the broad field of applied chemistry."

—M. C. Whitaker in *Journal of Industrial and Engineering Chemistry*.

"The last volume fully maintains the standard of the earlier parts of the work, most of the articles written by acknowledged authorities being models of concise and up-to-date knowledge."—*Athenaeum*.

"If every manufacturer is wise enough to add this work to his library he will have available a mine of information that will constantly save him fruitless inquiry and laborious research. . . . Worth a whole library of ordinary chemical literature."—*Drugs, Oils, and Paints*.

Heredity and Eugenics

By John M. Coulter, William E. Castle, Edward M. East,
William L. Tower, and Charles B. Davenport

THIS book consists of a series of public lectures delivered at the University of Chicago. The lectures were given partly by members of the University Faculty, and partly by investigators from other institutions. As all these men are distinguished for work in these fields, the subject is summarized in an unusually authoritative way. The purpose of the volume is to present to the intelligent public an account of the more important and interesting movements in biology. It is profusely illustrated.

I. PRACTICAL PURPOSE OF THIS MEETING

THIS meeting is the outcome of conversations which resulted from the recent book of Dr. Henderson on "The Fitness of the Environment." Yet this company is not called for the sake of discussing, on the present occasion, that book, or any of the scientific problems which it more directly considers. The connection, then, between Dr. Henderson's book and this evening's undertaking needs some explanation. As you know from the wording of the call to which you have so kindly responded, one principal purpose which I have in mind as I address you is practical. I shall ask you, before the evening is done, to give some thought to the question: Is it advisable for us to meet again occasionally, as opportunity offers, in order to discuss some questions of common scientific interest. You represent various departments of research. Is it worth while for you, or for some of you, at your own pleasure, to come together in such a way as the present one, in order to take counsel about different problems which belong, not only to a single science, and not only to some special group of sciences, but also to the realm which is common to a decidedly wide and varied range of scientific inquiries?

My part in this evening's discussion is determined by this practical question. I can not come here as a representative of any one department of research in natural science. I am limited in my present undertaking to such an appeal as a student of philosophy may have a right to address to

MSS. Intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

a company of scientific men, when he wishes to ask them a practical question whose answer concerns them all.

The only justification which I have for addressing you is that the habits of a student of philosophy, and, in particular, of a student of logic, make him sensitive to the value of a comparative scrutiny of the methods, the conceptions and the problems of various sciences.

If the main topic of the evening is a question relating to the practical value of some new mode of cooperation, in which a number of representatives of different departments of scientific research are to be asked to take part, the student of philosophy may possibly serve as a sort of traveling agent. For the kind of cooperation to which I have been asked to invite your attention would involve, if it succeeded, certain journeys which some of you might thereby be induced to make into the provinces of your colleagues. Widely traveled though all of you are, these journeys may lead occasionally to novel incidents, and may please or arouse you in new ways. My business, I say, is to act this evening merely as such a tourist agent, describing and praising as I can the new kind and combination of journeys to which my agency proposes to invite you.

Philosophy itself, in so far as it is a legitimate calling at all, may in fact be compared to a sort of Cook's bureau. Its servants are taught to speak various languages—all of them ill—and to know little of the inner life of the numerous foreign lands to which they guide the feet, or check the luggage of their fellow-men.

But if new comparative studies of the ideas of various and widely sundered provinces of research are to be carried out at all, Cook's agents, tedious as they often are, have their part to play. Regard me, then, if you wish to vary the name, as represent-

ing this evening some bureau of university travel.

II. PRELIMINARY VIEW OF THE THEORETICAL PROBLEM OF THIS PAPER

Speaking seriously, let me say that my task, upon its theoretical side, involves undertaking to present to you, in a perspective which may prove to be not wholly familiar, an outline sketch of certain conceptions and methods which actually belong to widely various sciences. These conceptions and methods in some measure concern you all, and, in our day, they are undergoing various changes, and are being applied to new problems.

The problems of each science are its own affair; but they also concern the whole body of scientific workers. To look over a somewhat wide range of scientific work, not for the sake of contributing to the researches of any one special science or group of special sciences, but for the sake of studying for their own sake some of the most general ideas and methods that are used by various scientific workers—this is, at the present time, a legitimate undertaking, and, in view of what has already been done, and is now under way, is not a hopeless undertaking.

The perspective in which such a study may place the problems of other people may help them to understand one another better. My task, on its theoretical side, is limited this evening to a few such general methodological remarks. These remarks may then lead us back to our practical question.

III. THE PROBLEM OF VITALISM

The name vitalism is often given to those doctrines which have used the hypothesis that the phenomena of living organisms are due to some process which is essentially identical in its nature with the process ex-

emplified by our own conscious voluntary activities. We deliberate, plan and choose. It seems to us as if certain things and occurrences in the world were due to these our plans and choices, and are different from what they would be were our will not a factor in the world-process. On the other hand, some things and events in the natural world—notably the recurrent movements of the heavenly bodies, and the processes which attend the workings of machines, seem to us to be, in some or in many respects essentially different from the processes which result from our plans, our choices and our voluntary deeds. What is called a mechanical theory of nature, or, more generally still, materialism, undertakes to account for the vital processes, for the activities of organisms, by supposing that they too are not essentially different from the other material processes, and that they really exemplify the same natural laws which the movements of the heavenly bodies and the workings of machines illustrate.

The contrast between vitalism and materialism is, in the history of science and of philosophy, very ancient. The Greeks began with doctrines which were, in a somewhat confused way, both materialistic and vitalistic. The natural world was viewed as, in one of its aspects, a sort of machine, a chariot whose mechanical movement was an essential feature of its very being. The natural world was also regarded as through and through alive—a world of love and strife, of mixing and of sundering, of wisdom and of something resembling contrivance.

To this early Greek vitalism, which had various forms, the materialism of Democritus opposed a mechanical theory of nature which was much more ingenious and considerate than were the earliest forms in

which the machine-like aspect of nature was described. On the whole, however, vitalism, the doctrine that nature acts not in vain, but in an essentially planful and designing way, was predominant in Greek thought.

The greatest Greek vitalist was Aristotle. Materialism remained in the background of ancient thought, and was destined to be revived, and to take on the form of the modern mechanical theory of nature, only after the beginnings of the new science in the seventeenth century of our era.

These ancient problems as to whether nature is rather a mechanism or an expression of something which essentially involves or resembles wisdom and contrivance, are certainly not questions which belong to any one natural science or group of natural sciences. From time to time, however, they come nearer to the surface of popular or of scientific discussion. The present is a moment when a certain interest in various forms of vitalism has once more become prominent in the discussions not only of philosophers and of leaders in popular inquiry, but of some professional students of the natural sciences of life as well.

I do not know how far it will prove to be interesting or profitable for you, as scientific men, to discuss, in your future meetings, if you have any future meetings, problems directly connected with vitalism, or with its old opponent, the mechanistic theory of the nature of life. I know only that when we mention such problems we call attention to one of the ancient boundary lines, or, as one may say, to one of the beaches where, in the realms of inquiry, sea and land come face to face with each other; so that two widely contrasting realms of nature here seem to clash. Here, then, the waves of experience tumble, and

the tides of opinion rise and fall. Here, then, for that very reason, and especially at this very time, new discoveries are likely to be made in especially impressive ways.

If you are to compare notes, it will therefore not be surprising to find that questions about the relations, the contrasts and the connections of life and of mechanism will become prominent in your discussions. My own preliminary remarks on the classification of scientific methods may well be guided, then, by some interest in the scientific processes which go on upon this old boundary line—this sea-beach—of opinion and of investigation, where the vast and doubtful seas of inquiry into the phenomena of life encounter, as it were, the firm land where the mechanical view of nature finds its best known illustrations.

IV. THE VITALISM OF ARISTOTLE

It will help us in our survey of our problems about the contrasting ideas and methods followed by the inorganic sciences on the one hand and the sciences of life on the other hand, if we next say a word about one aspect of Greek vitalism which is frequently neglected.

Life-processes in general resemble our own human voluntary processes, as we have said, in so far as any living organism seems to us as if it were guided by some sort of design, and as if, through a kind of wisdom or contrivance it adjusted means to ends. To say this, however, and even to believe that this seeming is well founded, and that, in some wise living nature really is planful, and does embody something of the nature of will, or of purpose—to assert all this is not yet to decide how close the real resemblance is between the teleology of nature and the choices and contrivances of a man who is planning and who is exerting his will.

As a fact there have been many vitalists who thought nature, and in particular organic nature, to be purposive, but who did not believe that nature is clearly aware of her own designs.

There have been many vitalists who conceived of nature as in some sense even divine in its skill, but who did not accept theism either in its primitive or in its more cultivated forms. The design argument in its later theological formulations is not any classic argument for vitalism. All this becomes manifest if you look for a moment at Greek vitalism, and, in particular, at the vitalism of Aristotle.

The Greek vitalists well knew that nature, however wise she seems to be, does not show signs of deliberating like an architect before he builds a house, or of piecing together her works as a carpenter devises a chest or a bed. For the Greek vitalist, and, in particular, for Aristotle, nature fashions, but not as a human mechanic fashions—piecemeal and by trial and error.

Nature's skill is (so such vitalists think) more like that of a creative artist, who does not pause to know how he creates. If ideas inspire the artist, he does not reflect upon what they are. Just so, while the being whom Aristotle calls God, who is conceived to exist quite apart from the world, is indeed self-knowing and is wisely self-observant, Aristotle's God is not the God of the later design argument. For he neither creates nor fashions the natural world. Nature, in Aristotle's opinion, is not God, and is not God's handiwork, but is, with a certain instinctive and unconscious wisdom, a sort of artistic imitator of God's wisdom. And this natural process of imitating the divine perfection by quickening a material world with a tendency to be fashioned after

a divine pattern—this process constitutes the life of the natural world.

The designs which nature expresses are therefore for Greek vitalism not the conscious designs of anybody—either God or man. They are the creative tendencies which embody themselves in the material world, by a process which we can best compare with the workings of instinct or of genius.

Now modern vitalism is far away from its Greek forerunners, but whenever, for any reason, vitalism becomes afresh interesting to any group either of philosophers or of scientific workers, it is well to remember that the contrast and the conflict between a mechanical view of nature and a vitalistic view has hardly ever been limited to the decidedly special and artificial antithesis between blind mechanism, on the one hand, and conscious or deliberative design, on the other hand. For even our human art is, as Aristotle remarks, partly guided by a skill which is not conscious and is not deliberate. That which, in recent years, Bergson has called *élan vital*—the creative vital power, was well known, in their own way, to the Greeks.

Different as Bergson's vitalism is from that of Aristotle, the ancient view and Bergson's vitalism have in common the belief that life means a process of which the instinctive skill and the artistic genius of man give examples. The problem of vitalism is always the problem as to how such unconscious skill, such undeliberative art, is made possible.

And so, even in this sketch of the varieties of scientific method, I shall in passing name to you one way in which some of the newest hypotheses may enable us to face, and perhaps in some measure to clarify, the problem as to how this stimulation of conscious designs by processes which are themselves

unconsciously or, so to speak, blindly wise, is a possibility in the natural world.

V. THREE TYPES OF KNOWLEDGE: THE HISTORICAL, THE MECHANICAL AND THE STATISTICAL

So much must suffice as an introductory word regarding those problems about vitalism and mechanism which have recently been revived, and have brought us together. Herewith we are ready to proceed to our classification of the conceptions and the methods which have been and which may be used in dealing with such a range of problems as is this.

The attempt to sketch in a preliminary way what these conceptions and methods are can be preserved, I think, from vagueness, if I begin by using the guidance of a man of whom you all are accustomed to think as a true natural philosopher—one who was possessed of a very exact sort of scientific knowledge, and who was a great scientific discoverer. He was also very fond of a comparative study whereby he lighted up his own researches through thoughts that came to him from far-off fields. I refer to Clerk Maxwell. In a paper whereof some fragments are printed in his biography, as well as in various remarks in his published writings, Clerk Maxwell more than once used the classification of scientific knowledge which I shall here employ for our present purpose. Natural science, in so far as it studies the processes of the natural world, has three kinds of objects with which it deals. And it adjusts itself to these three kinds of objects by methods which, in each of the three fields thus defined, vary widely from one another; while in each of the three fields both the conceptions and the methods used have much in common, and much too whereby each of the three fields differs from the others. The three sorts of ob-

jects are: (1) Historical objects, (2) mechanisms, and (3) statistically defined assemblages. The three sorts of methods are: The historical, the mechanical and the statistical.

Clerk Maxwell's few but momentous observations upon these three fields of scientific knowledge have a beautiful brevity, and show a fairly poetical skill of imagination whereby he finds and expresses his illustrations both of scientific ideas and of methods. I can not follow the master in his own skill. And I shall be unable to use his language. I must portray his classification in my own way, and must use my own illustrations.

If you wish to come into closer touch with this aspect of the master's thought, you may use the concluding passage of his famous elementary treatise on the "Theory of Heat," and several remarks in his article on "Atoms" in the ninth edition of the *Encyclopedia Britannica*. In addition I may refer you to the citations made by Theodore Merz in the eleventh chapter of Volume II. of his "History of European Thought in the Nineteenth Century" (pp. 599, 601 and 603).

Let me briefly review, with a few illustrations, this classification of the three fields and the three methods of natural science.

Science deals either with substantial things (such as atoms or organisms) or else with events. Let us confine ourselves here to the works of science in its dealings with natural events and processes. Science deals with the historical when its objects are individual events or complexes of events, such as is a single solar eclipse, or such as is the birth or the death of this man, or the performance of just this act of choice by this individual voluntary agent.

Science deals with the mechanical when its objects are the invariant laws to which

all the individual events of some field of inquiry are subject, and when such invariant laws actually exist, and can be used to compute and to predict actual events. Thus, if the acceleration which every individual body belonging to a system of material bodies undergoes depends at every instant, in an invariant way, upon the spatial configuration of the system of bodies at just that moment, the system is a mechanical system—such, for instance, as a system of bodies moving in accordance with the Newtonian law of gravitation.

Science deals, in the third place, with the statistical, when it studies the averages in terms of which aggregates or collections of events can be characterized, and when it considers not the invariant laws, but the always variable possibilities that these averages will be subject to certain uniformities, and will undergo definable changes.

In brief, the object of historical knowledge is the single event, occurring, in the ideally simple case, to an individual thing. A free-will act or an observed eclipse serves as an example. The object of mechanical knowledge is the unchanging natural law under which every event of some type can be subsumed. Sometimes the object of mechanical science may be an individual event, but only in so far as, like the eclipse, it can be predicted by means of such an invariant law. The object of statistical knowledge is not the single event and is not the invariant law, but is the relatively uniform behavior of some average constitution, belonging to an aggregate of things and events, and the probability that this average behavior will remain, within limits, approximately, although always imperfectly uniform.

VI. APPLICATIONS OF THIS CLASSIFICATION

In view of this classification of the objects of scientific knowledge, you may see

at once that the issues between such doctrines as vitalism and a mechanistic account of nature appear, from the point of view of Maxwell's classification, in a somewhat unfamiliar perspective. For one need no longer merely contrast two views, the mechanical and the vitalistic. One now has a third and a mediating point of view to compare with both of them. The result is instructive.

Vitalism, whatever else it involves, always makes prominent some aspect of nature, and in particular some aspect of organic nature, such that this aspect is supposed to be, in some individual case, strictly historical. If an organism is due to a purposive process, if the reactions of an organism are, in any instance, events of the nature of conscious or of subconscious deeds—then something unique, historical and novel occurs whenever one of these vital processes is exemplified by an individual event.

On the other hand, if the mechanistic view of nature can exhaustively express the real facts, then the only natural events are of the type which the eclipses exemplify. The single events are, so to speak, points on a curve, selections from an ideal continuum whose constitution is definable in terms of an invariant differential equation.

But the third or statistical mode of viewing nature takes account of another aspect of the processes of nature. The world of the statistical view still contains events supposed to be unique and individual; but from the statistical point of view the main interest lies no longer in each event as it occurs, nor yet in its unique character. The statistical interest is directly concerned with a set or aggregate of events, with a discrete multitude of occurrences. These occurrences may prove to be examples of law. The statistical view is

deeply interested in finding that they are examples of law. But the law for which the statistical method seeks is no longer a law that is ideally statable in terms of an invariant differential equation or in terms of any other timeless invariant. When found, the statistical law is an account of a collection of facts in terms of averages involving many events.

This account takes some such form as saying: "The average magnitude or velocity or size or range of the events of the class *C* is approximately *V*." Or, again, the statistical view succeeds when we can say: "A proportion which is approximately *p* of the events of the class *a* have the character *b*." Or finally, one expresses the statistical view when one is able to assert: "There is a probability *q* that *c* differs from *d* by not more than such and such an amount,—say *X*." All such generalizations, where the objects in question are living organisms, relate to events, but neither to merely historical single events nor to events subject to fixed laws. The statistical laws are probable and approximate laws about numbers of events.

Laws and probabilities, stated in some such form as the one just suggested, constitute the characteristic formulas of the statistical view of nature.

It is easy to illustrate how the statistical view contrasts with both the mechanical and the historical point of view by considering how each point of view applies to an event such as is expressed by the assertion: "*A* killed *B*."

For a strictly historical point of view this event, this homicide, is an unique occurrence—possibly a free-will act. It falls under moral and criminal laws, but these relate only to its value and its legal consequences. The interest of the case for a judge or a jury lies in its novelty—and in its uniqueness. For a strictly mechanical

view of things the killing resembles an eclipse. Unique as it is, it is supposed to have been essentially predictable. Perhaps if you had known the precise configuration and the accelerations of all the physical particles in the world at some appropriate moment, then this killing could have been calculated in advance. It is a mere case of a law—an eclipse, so to speak, of some sun—a point on some curve.

But for a statistical view the single killing of *B* by *A* is an event against which an insurance provision could have been made in advance—not because any mortal could have predicted whether or no *A* would kill *B*, but because the death-rate of men of *B*'s age and occupation can be statistically known with approximate and probable accuracy, so as to make a policy insuring *B*'s life a contract whose value is calculable, not on mechanical but upon statistical grounds.

Now you will easily recognize that the actual knowledge of vital phenomena which science possesses is, in the main, a statistical knowledge. It is the sort of knowledge which the mortality tables of the insurance companies exemplify. We know little of the history of individual organisms, and less of their mechanism, but we can and do study the statistics of groups of organisms. In such statistical terms heredity and variation are now constantly investigated. In such terms growth and disease, as well as death, economic prosperity and social transformations, financial and political processes, the geographical distribution of organisms and the gradual accumulation and change of the material as well as the mental products of civilization—in such statistical terms, I say, all such things come to be the objects of scientific description and explanation. To give an account of the special phenomena of life in terms of mechanism remains in practise

a remote ideal, despite all the proofs that the vital processes, being subject to physical and chemical laws, must be, in some sense, if not wholly, then very largely mechanical in their nature. Life may be a case of mechanism; but its phenomena are best known to science in terms of statistical averages, of laws which hold approximately true regarding these averages, and of probabilities which are definable in such terms as are used when the insurance value of a life-policy is computed. The logic of the insurance actuary is essentially the same as the logic which is consciously or unconsciously used in dealing with all forms and grades of vital processes.

This general rule regarding the methods of the sciences of life is well known to you. For it is also known that, just as a mechanical theory of the details of the phenomena of life still remains a remote ideal, so too an historical knowledge of the individual events of the life of an organism is something which may possess upon occasion great moral or social or perhaps clinical interest, but can occupy but a part, and usually a very small part, of the interest of the sciences of life.

Into the study of human history itself, devoted as such a study naturally is to the sequences of individual events, natural science enters in so far as something of the nature of statistical knowledge is acquired. And therefore the use of deliberately statistical methods in historical study, the use which Dr. Woods has recently proposed—such a use, I say, is in principle nothing essentially opposed to methods long since in exactly and unconsciously employed. For the historiometry of Dr. Woods is in principle a legitimate extension and a logically legitimate refinement of the long since well-known disposition to explain human history in terms of "historical tendencies" and of "historical forces."

In fact, the term *tendency* is, in every exact usage which you can give it, an essentially statistical term. To say that *a* has a tendency to lead to *b* is to declare that *a* more or less certainly and definitely known proportion of events of the class *a* are followed by events of the class *b*.

To introduce statistics into historical study is simply to try to make some such assertions about tendencies exact.

The constant extension of the use of statistical methods in all the sciences of life is something as familiar as it is momentous. Its very familiarity, in fact, tends to blind the minds of many to its real importance. In truth, the statistical view of nature has a logic of its own. Its three fundamental conceptions, that of an average, that of approximation and that of probability, are indeed not the only fundamental categories of our thought, but they are conceptions which go down to the very roots of our own intelligence as well as of our voluntary activity. It seems increasingly plausible to assert that these three conceptions, while they certainly have their special province, still, within that province go down to the roots of that nature of things which our sciences are studying. At all events, I find it hard to exaggerate the importance of those methods and of those ideas of natural science which are definable in terms of approximation and of probability, in the modern sense of those terms.

When Clerk Maxwell made his threefold classification of scientific methods, he did so with his eyes well open to the fact that by the statistical view of nature, and by statistical methods in science he meant something much wider and deeper than is the mere commonplace that statistical tables can be made by the census bureaus, and can be used by the insurance companies, or applied to the discovering of various special

laws of nature. Let me remind you of what Maxwell had in mind.

VII. THE STATISTICAL VIEW IN PHYSICS

Clerk Maxwell was a physicist. His greatest treatise was that upon electricity and magnetism. The theory of electricity and magnetism follows methods which illustrate the mechanistic way of dealing with the problems of nature. Maxwell defined a system of differential equations in terms of which certain elementary electromagnetic processes can be expressed. Assuming these equations to be true, one can compute the consequences of one's hypotheses, as Newton computed the consequences of supposing the law of the inverse squares to be true for a field of gravitative force. One can then compare the computed results with experience, and upon such computation and comparison with experiment one's method in this case depends. Such is an example of the essentially mechanical view of nature.

But Clerk Maxwell, working as he did at a time when the general theory of energy was in its period of most rapid development, was not content to confine himself to problems of the type of the theory of electricity. He also had his attention especially directed to those physical processes which are illustrated by the diffusion of gases, by the irreversible tendency of energy to pass over from available to unavailable forms, and by various analogous phenomena which can not be expressed in terms of the classic types of mechanical theories.

Following the initiative of Clausius, but developing along lines of his own, Maxwell thereupon worked out his kinetic theory of gases. It is that theory of which he is thinking when he distinguishes the statistical way of viewing nature both from the historical and from the mechanical view.

In fact, when the kinetic theory of gases first defines its swarms of molecules, with their countless paths and collisions, it appears to be viewing a gas simply as a complex mechanism; and in certain respects this seeming is well founded. But the logic of the theory of probabilities, which the kinetic theory uses in deducing the physical properties of gases from the statistical averages of collisions and free paths of the hypothetical molecules, is no longer reducible to the logic of mechanics. For the velocity, the path, and the collision of each individual molecule are all indifferent facts for this kinetic theory of gases; which devotes itself to the study of probabilities and of tendencies. And its methods are in part those which the procedure of the insurance actuaries exemplifies. The logic in question is one which in some respects still needs further elucidation. For even up to the present time the logic of the theory of probabilities is a controverted topic. But there are a few features of the situation about which nobody who looks carefully into the subject can retain, I think, any serious doubt.

First, then, the average behavior of a very large collection of irregularly moving objects has characters which are decidedly lawful, even although the laws in question are what may be called laws of chance.

The recent familiar use of statistical diagrams for illustrative purposes has made this law of chance more familiar to many classes of students than it was in the day when Maxwell wrote certain words, which you will find in his "Theory of Heat."¹ These words give you the very heart of the statistical aspect of nature.

The distribution of the molecules according to their velocities is found to be of exactly the same mathematical form as the distribution of observations according to the magnitude of their errors,

as described in the theory of errors of observation. . . . Whenever in physical phenomena some cause exists over which we have no control, and which produces a scattering of the particles of matter, a deviation of observations from the truth, or a diffusion of velocity or of heat, mathematical expressions of this exponential form are sure to make their appearance.

This, then, is in concrete form the law of random distribution, the form of iron necessity which one finds in the realm of chance.

All this law of chance variation was, of course, at that time no novelty, although the popular use of statistics has since made it more familiar. What was new, however, was the fact that when Maxwell computed the consequences which followed from supposing the existence of his swarm of colliding molecules with their chance distribution of velocities, he was able to deduce not only the principal physical properties of gases, but in particular those properties which, like all the phenomena which illustrate the second law of the theory of energy, are not expressible in terms of merely mechanical laws, unless these laws are applied to the case of a system complex enough to ensure that the velocities of its molecules shall approximate closely to this chance distribution.

Since Maxwell's time, the same theoretical methods have been applied to a vast range of physical phenomena, with the general result that the second law of the theory of energy is now generally regarded, by all except the extreme *Energetiker*, as essentially a statistical law. So viewed, the second law of energy becomes a principle stated wholly in terms of the theory of probability. It is the law that the physical world tends, in each of its parts, to pass from certain less probable to certain more probable configurations of its moving particles. As thus stated the second principle not only becomes a law of evolution, an historical principle, but also ceases to

¹ Page 309 of the Appleton edition of 1875.

be viewed as any mechanically demonstrable or fundamentally necessary law of nature. Whether nature is a mechanism or not, energy, according to the kinetic theory, runs down hill as it does for statistical and not for mechanical reasons. Energy need not always run down hill; and in fact would not do so if there were present in nature any persistent tendency, however imperfect, towards a suitable sorting of molecules. Maxwell suggested in his image of the demons sorting the atoms of a gas, how such a tendency might make energy run up hill instead of down, without the violation of any mechanical principle.

More recently Boltzmann, in his further development of Maxwell's hypothesis, pointed out how the theory of probability itself requires that, in the course of very vast intervals of time, there must occur some occasional concentrations of energy and some sensible unmixings—some reversals of the diffusion of gases, in case indeed the kinetic theories are themselves true. And still more recently Arrhenius has suggested that the nebulae may furnish the conditions for the occasional if not the general reversal of the second law of the theory of energy. Of such speculations I can of course form no judgment. They interest us here only as examples of the logic of the statistical view of nature.

In sum, all these investigations have tended to this general result: If a law of the physical world does not appear consistent with the mechanical view of nature so long as you confine your attention to a single system of bodies, whose individual movements you follow and compute, this law may still become perfectly intelligible when viewed as the expression of the average behavior of a kinetic system complex enough to give an opportunity for the application of statistical laws, and for the use of the conception of probability.

VIII. THE CANONICAL FORM OF SCIENTIFIC THEORIES

All the foregoing instances may appear to you merely to suggest that, in dealing with mechanisms too complicated to be the object of a direct computation, our ignorance may force us to make use of statistical modes of computation. These statistical methods, you may say, are convenient devices whereby we neutralize, for certain special purposes, the defects of our mechanical knowledge.

If the insurance actuaries—so you may say—could use a sufficient knowledge of the world's mechanism, they would compute the precise time when each individual man is to die, just as the astronomers compute the eclipses. An almanac of mortality would take the place of the present nautical almanac. Everybody's funeral would be announced, if that were convenient, years in advance; and life insurance would appear to be a blundering and awkward substitute for scientific prediction. Because and only because, as a fact, no knowledge of the differential equations of the precise movements of matter, and no exact measurements of the accelerations or of the other rates of change in these movements gives us the power to predict the phenomena of nature in their detail, including the movements which determine life and death, we are obliged to substitute a statistical definition of the probable tendencies of a definable proportion of great numbers of men to die, in a way which varies with their numbers and their ages, for the precise knowledge of the hour of each man's death which we should all regard as a scientific ideal, if we could know the mechanism of life and death. The statistical view is a mere substitute for a mechanical view which our ignorance makes us unable to use, in the individual case, with sufficient accuracy. Such may be your comment.

The nautical almanac (so you may say) is the model of what applied science ought to be. The mortality table is the convenient summary due to a necessary scientific evil. It is a device for recording our ignorance of the details of the world's mechanism along with our imperfect knowledge of certain probable and approximate tendencies to which the averages of many human lives are subject.

In other words, you may be disposed to insist: "Mechanical theories are the canonical forms towards which a growing scientific knowledge guides our way. Computations of individual events in terms of invariant laws whose validity is independent of time, are the models of what our scientific ideals seek. The statistical view of very complex mechanisms is an asylum in which our ignorance, perforce, has to find its refuge whenever, as in case of the swarms of molecules and the labyrinthine complications of organisms, the mechanical view of nature, as applied by us, loses its way."

In answer to this very natural comment, I am next led to say that, whether the natural world is a mechanism or not, the statistical view of nature would be, and so far as we know the facts is, applicable to sufficiently complicated systems of things and events, not as a mere substitute for these more exact computations which our ignorance of mechanical laws makes necessary, but as an expression of a very positive, although only probable and approximate, knowledge whose type all of the organic and social sciences, as well as most aspects of the inorganic sciences, illustrate. There is therefore good reason to say that not the mechanical but the statistical form is the canonical form of scientific theory, and that if we knew the natural world millions of times more widely and minutely than we do, the mortality tables and the computa-

tions based upon a knowledge of averages would express our scientific knowledge about individual events much better than the nautical almanac would do. For our mechanical theories are in their essence too exact for precise verification. They are verifiable only approximately. Hence, since they demand precise verification, we never know them to be literally true.

But statistical theories, just because they are deliberate approximations, are often as verifiable as their own logical structure permits. They often can be known to be literally, although only approximately, true.

This assertion is, in its very nature, a logical assertion. It is not any result of any special science, or of any one group of sciences. It solves no one problem about vitalism. It is a general comment on the value of the statistical point of view.

But, if the assertion is true, it tends to relieve us from a certain unnecessary reverence for the mechanical form of scientific theory—a reverence whose motives are neither rationally nor empirically well founded. It is the merit of Charles Peirce to have emphasized these logical considerations. Their importance for the study of scientific methods has grown greater with every year since 1891, when he began the publication of his remarkable papers in the *Monist*, entitled: "The Architecture of Theories," "The Doctrine of Necessity Examined" and "The Law of Mind." These papers are fragmentary; and yet in their way they are classical statements of the limitations of the mechanical view of nature, and of the significance of the statistical view of nature.

As I close, let me merely outline some aspects of Peirce's extension of the statistical view of nature beyond the range which Maxwell's and Boltzmann's study of the theory of gases directly exemplified.

IX. APPLICATIONS OF THE STATISTICAL VIEW
TO THEORIES OF NON-MECHANICAL
SYSTEMS. AGGREGATION AND
ASSIMILATION AS STATIS-
TICAL TENDENCIES

It at first seems, I have said, as if the statistical methods of the kinetic theory were applicable only to mechanisms whose complications were too vast to make it possible to follow in individual detail their necessary sequences of movements.

But this seeming is unfounded. Let me summarize in my own words a few considerations which Peirce summarily states, and which, to my mind, get a constantly increasing importance as the statistical view of nature comes to be applied to wider and wider fields of research.

Suppose an aggregate of natural objects which contains a very great number of members, each one of which is subject to some more or less exhaustively definable range of possible variations. These objects may be things or events, at your pleasure. They may be molecules or stars or cells or multicellular organisms or members of a society or observations of a physical quantity or proposals of marriage or homicides or literary compositions or moral agents or whatever else you will. The essential basis which is needed for a statistical view of such an aggregate is this:

First, the members of each aggregate must actually form a collection which is, for some physical or moral reason, a genuine and therefore in some way a definable whole.

Next, some more or less systematic tendency towards a mutual assimilation of the fortunes, the characters or the mutual relations of the members of this aggregate must exist. This tendency toward mutual assimilation may be of very various sorts.

The policyholders of an insurance company tend to assimilate the fortunes of

their various investments when they all of them pay their premiums to the same company. The stars tend to a certain assimilation of the mutual relations amongst those photographs of their various spectra which chance to get collected on the photographic plates of the same astronomical observatory. For, as a consequence of this aggregation of photographs, the stellar spectra in question may tend to be classified; and the logical, as well as the other socially important, and the physical fortunes of objects which are once viewed or arranged or tabulated as objects belonging to the same class, tend, in general, to a further mutual assimilation.

Birds of a feather not only flock together, but tend to get statistically similar fortunes, when they come into chance contact with other birds or with breeders, with hunters or with biometrical statisticians.

All objectively well-founded classification is not only founded upon real similarities amongst the objects which belong to an aggregate, but tend to some increase of these similarities, in so far as these objects are not changeless mathematical entities, but are natural objects, whose fortunes are subject to change.

One of the most widely applicable laws of nature is, in fact, the law, wholly indefinable in mechanical terms, but always expressible in terms of statistical tendencies—the law that aggregation tends to result in some further and increasing mutual assimilation of the members of the aggregate. This assimilation may express itself in the fact that one classification or aggregation leads both logically and physically to another and deeper and also wider aggregation.

If the stars are already physically classified into two distinct drifts, which move through each other in two different directions, and if the stars in question tend to

get the photographs of their spectra assembled in the same observatory, then the classes into which the photographs tend in the long run to be grouped also tend to be such that, at least for some one resulting classification or aggregation of the photographs, the photographs of the spectra of the stars of one of the star drifts are grouped together, not only in the ideas which the astronomers form, but in the physical arrangements towards which certain groups of photographs, of symbols and of statistical tables, persistently tend.

The principles here involved depend upon the sorts of assimilation which the radiant phenomena of light make possible. For a photograph is a physical expression of a certain tendency whereby the structure of a photographic plate tends to be assimilated to the molecular structure and state of a radiating object—say a star. When the photographs of stellar spectra are grouped in classes, a secondary assimilation tends to take place, since similar spectra tend to get either placed or tabulated in similar ways. When this secondary assimilation of the photographs leads to an indirect discovery of the existence of the two star drifts themselves, a tertiary assimilation of the fortunes of those stars whose proper motions are sufficiently similar takes place, and tends to get represented in the knowledge of different astronomers.

The ideas of these various astronomers tend to further assimilation through the means used in scientific communication. The radiation of scientific knowledge continues the natural process which the radiation of light and the making of photographs of stellar spectra have already illustrated, and the rule continues to be illustrated that mutual assimilation is one aspect of classification and aggregation, and is a cumulative statistical tendency which accompanies them both.

The insurance companies and the transformation of modern civilization through the extension and aggregation of modes and devices whereby insurance is accomplished, furnish numerous other examples of this law of the fecundity of aggregation. The law, as I have said, holds in general for non-mechanical systems, although, as stellar evolution seems to indicate, it can also hold for mechanical systems. It may hold, in fact, for all natural processes which involve evolution.

Clerk Maxwell himself believed that the sharp distinctions which separate the different classes of elementary atoms, and the different types of molecular structure which determine the spectra of the molecules of different elements, are signs that no kinetic theory of the evolution of the chemical elements would ever be possible. It is precisely here that the latest advances, on the still so imperfectly defined outlying boundaries of physical and of chemical research, give a new significance to the statistical view of nature, by showing that if we take account of sufficiently large aggregates of things and of events, a kinetic theory of the evolution of chemical elements becomes a possibility worthy of future investigation, and certain to receive, in connection with the phenomena of radioactivity, further investigation upon statistical lines, whatever be the further fortunes of the mechanical view of nature, or of this problem about the evolution of the elements.

Of such speculations one can say that, if ever a theory of the evolution of the chemical elements becomes feasible, it will be, in part at least, a statistical theory, and will illustrate in new ways how widespread in material nature is the tendency to that mutual assimilation which all the phenomena of radiant energy illustrate, and of which the relatively uniform constitution and distribution of each one of the various chem-

ical elements through vast ranges of the physical universe may well be the result.

In brief, the evolution of stars, of elements, of social orders, of minds and of moral processes, apparently illustrates the statistical fecundity of nature's principal tendency—the tendency to that mutual assimilation which both defines aggregates, that is, real classes of natural objects, and tends to keep these classes or aggregates permanent in the world and to increase both their wealth of constitution and their extent.

Now it is this principle of the fecundity of aggregation which seems to be the natural expression, in statistical terms, for the tendency of nature towards what seems to be a sort of unconscious teleology—towards a purposiveness whose precise outcome no finite being seems precisely to intend. It is a statistically definable rule that changeable aggregates, when they are real at all, result from likenesses which their very existence tends both to increase and to diversify. The social fecundity of the principle of insurance illustrates this natural tendency. That marvelous result of the aggregation of scientific observers, of tabulations and of photographs, of the radiant phenomena which make the stars visible and of the microscopic phenomena and the logical interests which make probability definable—that marvelous result of these various aggregations which constitutes the whole procedure and outcome of modern inductive science itself, is an expression of this same general tendency—apparently the most vital and the most vitalizing tendency both of the physical and of the spiritual world—the tendency of aggregation and of classification to be fruitful both of new aggregations and of the orderly array of natural classes and of natural laws.

In the purely logical and mathematical worlds this tendency can get, and does get, precise description in terms of the pure

logic of number and of order. In the physical world, in the world of time and of change, this principle gets further expressed as a statistical rather than a mechanical law—the law that classes, aggregations and organizations tend towards a definable sort of evolution.

As Charles Peirce pointed out, you need not suppose the real world to be mechanical in order to define and to conceive this sort of evolution. You need only suppose (1) the presence of the just-mentioned tendency to form aggregates, and to the mutual assimilation of the various parts of nature; (2) the statistically definable tendency to some sort of sorting or selection of the probable results to which any definable average constitution of the natural world at any moment leads; and (3) a tendency—and once more, a statistical and non-mechanical tendency, towards a formation of habits, and towards a repetition of such types of movement as have once appeared. Suppose these three tendencies (aggregation, selection and habit—and the statistical method shows these three to be widespread in the physical world); suppose these three, and you can define a process of evolution, never mechanical and never merely expressive of any previously settled designs, either of gods or of men. This process of evolution will then lead from mere chance towards the simulation of mechanism, from disorderly to a more orderly arrangement, not only of things and of individual events, but of the statistically definable laws of nature; that is, of the habits which nature gathers as she matures. The philosophy of nature which will result will show how nature may well tend to appear in certain aspects more and more teleological, and to manifest what Greek vitalism found in nature. Whether the whole world is ultimately and consciously teleological or not, this view of nature would of course be unable to decide. But it would lay stress upon

the thought that what is indeed most vital about the world is that which also characterizes the highest life of the spirit, namely, the fecundity of whatever unites either electrons or souls or stars into streams or into other aggregations that, amid all chances, illustrate some tendency to orderly cooperation.

If this view of nature has any foundation, gentlemen, then, as the whole progress of inductive science illustrates, the way to further such scientific evolution is to get together, and to leave the rest to the statistically definable tendencies of nature. These are tendencies away from the chance distributions which the bell-shaped curve of random distribution illustrates, towards the orderliness of which the mechanical view of nature gives us one illustration, and by no means the most probably true illustration.

I should suppose, then, that whatever notes you may compare in these meetings, you will probably frequently and variously illustrate the statistical view of nature. This view is ill understood by those who think only how dry statistical tables and averages may seem. Mechanism is rigid, but probably never exactly realized in nature. But life, although it has its history, has also its statistics. And averages cease to be dry when they are averages that express the unities and the mutual assimilations in which the common ideals and interests, the common hopes and destinies of the men, of the social orders, of the deeds—yes, and perhaps of the stars and of all the spiritual world are bound up and are expressed.

Do you wish to experiment upon some new processes of social aggregation, of mutual assimilation, and of the study of photographs of your various spiritual spectra?

This practical question is for you to consider.

JOSIAH ROYCE

HARVARD UNIVERSITY

THE NATIONAL ACADEMY OF SCIENCES

THE annual meeting of the Academy will be held in Washington on April 21, 22 and 23, 1914. Following is the tentative program:

MONDAY EVENING, APRIL 20

7:30 P.M.—Meeting of the council in the private dining-room of the Cosmos Club.

TUESDAY, APRIL 21

10:00 A.M.—Business meeting of the Academy in the Oak Room of the Hotel Raleigh.

1:30 P.M.—Luncheon in the private dining-room of the Hotel Raleigh. (In the event of unfinished business, an adjourned business session may be held in the Oak Room following the luncheon.)

4:00 P.M.—Auditorium, National Museum. Inauguration of the William Ellery Hale Lectures by Sir Ernest Rutherford, of the University of Manchester. (Open to the public.) Subject: "The Constitution of Matter and the Evolution of the Elements." (Illustrated.)

9:30 P.M.—Reception to the members of the Academy and their guests, at the home of Alexander Graham Bell.

WEDNESDAY, APRIL 22

10:00 A.M.—Auditorium, National Museum. Public scientific session for the reading of papers.

1:00 P.M.—Luncheon in the Oak Room of the Hotel Raleigh.

2:30 P.M.—Auditorium, National Museum. Public scientific session for the reading of papers.

8:00 P.M.—Annual dinner of the members of the Academy and their guests in the Oak Room of the Hotel Raleigh.

At the annual dinner of the Academy will occur the first presentation of the medal for "Eminence in the Application of Science to the Public Welfare" to George Washington Goethals and William Crawford Gorgas for distinguished service in building the Panama Canal. (Presentation private.)

THURSDAY, APRIL 23

10:00 A.M.—Oak Room, Hotel Raleigh. Business meeting of the Academy for the election

of members, foreign associates and two members of the council.

1:30 P.M.—Luncheon in the private dining-room of the Hotel Raleigh.

4:00 P.M.—Auditorium, National Museum. Second of the William Ellery Hale Lectures, by Sir Ernest Rutherford, of Manchester. (Open to the public.) Subject: "The Constitution of Matter and the Evolution of the Elements." (Illustrated.)

The chairmen of the various trust funds are requested to present at the meeting detailed written reports in accordance with instructions in rule 22, adopted at the annual meeting in 1911, which reads as follows:

The annual reports of the Committees on Research Funds shall, so far as the Academy has authority to determine their form, give a current number to each award, stating the name, position and address of the recipient, the subject of research for which the award is made, and the sum awarded; and in later annual reports the status of the work accomplished under each award previously made shall be announced, until the research is completed, when announcement of its completion and, if published, the title and place of publication shall be stated, and the record of the award shall be reported as closed.

At the scientific sessions of the academy, held in the Auditorium of the National Museum on April 22, papers will be presented as follows:

Pre-Cambrian Algonkian Algæ: CHARLES D. WILCOTT. (Lantern slides.)

Hewettite, Metahevwettite and Pascoite, Hydrous Calcium Vanadates: W. F. HILLEBRAND, N. E. MERWIN AND FRED E. WRIGHT.

Two apparently different calcium vanadates are described, which resemble each other very closely and have the same composition— $\text{CaO} \cdot 3\text{V}_2\text{O}_5 \cdot 9\text{H}_2\text{O}$ —when holding their maximum water content at room temperature. One of them—hewettite—occurs at Minasragra, Peru, and has been noticed on a single specimen from Paradox Valley, Colorado. The other—metahevwettite—occurs at numerous localities in western Colorado and eastern Utah. Both minerals are sparingly soluble in water. A third calcium vanadate—pascoite ($2\text{CaO} \cdot 3\text{V}_2\text{O}_5 \cdot 11\text{H}_2\text{O}$)—is also described. This occurs with hewettite at Minasragra. It is very soluble in water. The first and second minerals are regarded as hydrated acid hexavanadates— $\text{CaH}_2\text{V}_6\text{O}_{17} \cdot 8\text{H}_2\text{O}$

—the third as a normal hexavanadate, $\text{Ca}_2\text{V}_6\text{O}_{17} \cdot 11\text{H}_2\text{O}$.

The reasons for specific separation of hewettite and metahevwettite are set forth in detail. All three minerals are so sensitive to changes in atmospheric humidity that their water content varies within wide limits at different times of the year. The removal of all or nearly all the water does not result in breaking down of the crystal structure, and until this has occurred the water is wholly or in great part taken up again when opportunity is offered.

The importance is emphasized of bringing all minerals that behave in this way to a definite maximum water content before analyzing them and of following carefully the course of dehydration under prescribed conditions. Detailed directions are given for such tests and for avoiding several sources of error. Attention is also called to two fairly constant associates of metahevwettite. One of these (also a constituent of carnotite ores) is a gray hydrous silicate of aluminum, trivalent vanadium and potassium. The other is elemental selenium, the existence of which as a mineral species seems now for the first time established.

The Origin of Monocotyledony: JOHN M. COULTER.

The evidence of vascular anatomy, supported by the historical record, as well as by general morphological considerations, has demonstrated that the Monocotyledons have been derived from the Dicotyledons. It remained to obtain evidence of the transition from dicotyledony to monocotyledony. The two opposing views, each supported by considerable indirect evidence, are (1) that the monocotyledonous condition has arisen by a fusion of the two cotyledons, and (2) that it has arisen by a suppression of one of them.

Material of *Agapanthus umbellatus* (Liliaceæ) obtained from South Africa proved to be occasionally dicotyledonous, so that it was possible to determine the relation between the two conditions. The result has shown that neither one of the theories advanced to explain the origin of monocotyledony is tenable, but that this condition arises from the continuation of one growing point on the cotyledonary ring rather than a differentiation of two growing points. In every case, the cotyledonary apparatus begins as a ring, and continues its growth as one cotyledon or two. It is evident that there is neither suppression of one cotyledon nor fusion of two.

Heredity of Some Emotional Traits: CHARLES B. DAVENPORT.

Among emotional traits, violent temper and un-

controllable eroticism have an hereditary behavior that indicates that they are each due to a single positive determiner which may be regarded as interfering with the inhibitory mechanism. With a slightly less certainty marked cases of "Wanderlust" appear to be inherited as if sex-linked. Illustrated by diagrams and lantern slides.

The Causes of the Clotting of Blood: W. H. HOWELL.

In circulating blood or lymph a small amount of prothrombin is contained in solution in the plasma. This prothrombin is prevented from reacting with the calcium to form thrombin by the presence of an adequate amount of antithrombin, or, if any thrombin is formed, its coagulating effect on fibrinogen is prevented by the antithrombin. The normal fluidity of the circulating blood is dependent, therefore, upon the presence and action of the antithrombin. In blood-platelets and in leucocytes there is contained a supply of thromboplastic material (phosphatid-compound) and also of prothrombin. On the shedding of blood the disintegration of the platelets and, to a lesser extent, of the leucocytes liberates thromboplastin and prothrombin. The former neutralizes the antithrombin, the latter, together with the prothrombin already present in the plasma, is changed to thrombin by the action of the calcium. Cell-free plasmas may be clotted by the addition of thromboplastin (kephalin) to neutralize the antithrombin.

The Luminescence of Kunzite: EDWARD L. NICHOLS AND HORACE LEONARD HOWES.

The Prompt Distribution of Convulsants in Cardiotomized Frogs deprived of their Lymph Hearts: S. J. MELTZER.

Several years ago the writer reported that in frogs from which the heart was removed, an injection of strychnin, morphin or acid fuchsin brought on convulsions. For the two latter substances the effect was more prompt and rapid than in animals with normal circulation. The conclusions seemed to be inevitable that the distribution of these substances must take place by some mechanism other than the circulatory apparatus. Two years ago J. J. Abel stated that the success of the experiment depends upon the normal activity of the two anterior lymph hearts; when these are destroyed no convulsions can take place. In recent experiments carried out by Githens, of the Rockefeller Institute, Dr. Joseph, of the University of St. Louis, and by myself in a long series of experiments the lymph hearts were destroyed and after a day or

two, when the animals recovered, the heart was removed and the substances injected. The result was as prompt as if the lymph hearts were intact. Furthermore the injections were made this time into the lymph sacs of the thigh and the substances therefore had to travel long distances. Apparently a quite efficient distribution may take place through the connected lymph spaces without the aid of any part of the circulatory apparatus.

Contributions to the Geology of Bermuda: L. V. PIRSSON AND T. WAYLAND VAUGHAN.

Recently a deep well, about 1,400 feet deep, has been bored in Bermuda Island. The samples taken from this well at regular intervals show that there is first penetrated a considerable depth of lime deposits produced by organic life, then follows, down to about 600 feet, brownish weathered igneous rock, after which black unoxidized lavas and igneous material persist to the bottom. The lime deposits contain the remains of organisms. The facts disclosed have important bearings on the origin and geological history of the island and on the problem of coral reef formations. The igneous geology is discussed by L. V. Pirsson and the later history and coral reef problem by Dr. Vaughan.

The lectures founded in memory of the late William Ellery Hale, of Chicago, will be inaugurated by Sir Ernest Rutherford, of the University of Manchester, who will speak in the Auditorium of the National Museum, Washington, D. C., on April 21 and 23, 1914, at 4 P.M.

The committee in charge has planned a series of such lectures covering several years on the general subject of evolution, which is designed to give a clear and comprehensive outline of the broad features of inorganic and organic evolution in the light of recent research. Sir Ernest Rutherford's lectures will deal with the Constitution of Matter and the Evolution of the Elements. Aided by many illustrations, including some of the experiments which brought to him the award of the Nobel Prize, Sir Ernest will explain how the discovery of radio-activity and the study of the electron have revolutionized our views on the nature of matter. By these new means of investigation, the chemical elements and the complex compounds which they unite to form may be shown to consist of units of positive and negative electricity. Moreover, all nega-

tive electrons are precisely alike, from whatever form of matter they may be derived. Thus we are prepared to witness some of the transformations of the chemical elements, such as the spontaneous disintegration of radium and the production of helium from it.

These addresses on the fundamental structure of matter will prepare the way for succeeding lectures, which will deal with the various transformations of matter involved in the evolution of the earth and its inhabitants.

The second course in the Evolution Series will be given at the next autumn meeting of the Academy by Dr. William Wallace Campbell, director of the Lick Observatory, Mount Hamilton, California. Provided with his raw material, as it were, by Sir Ernest Rutherford, Dr. Campbell will sketch the various types of bodies which make up the universe, describe their connection in systems, and explain the principal theories of stellar evolution. His object will be to show how stars and stellar systems are gradually evolved from an earlier state and to afford a view of the earth in its first phases of development. In this way the intimate relationship of the earth with the moon and the other bodies of the solar system will be made apparent, as well as the continuity of the process which connects the present with the remote past. Dr. Campbell will introduce some of the results of his extensive researches with the powerful instruments of the Lick Observatory and will employ a large collection of astronomical photographs for illustration purposes.

A distinguished European geologist will be invited to give the third course of lectures at the annual meeting of the Academy in 1915. Taking the earth from the hands of the astronomer, he will show how its surface features have been altered in the process of time. Later lectures, preserving the continuity of the series, will then enter the field of organic evolution and illustrate the bearing of recent investigations in paleontology, zoology and botany on the evolution of plant and animal life. The evolution of man will form the subject of a subsequent course, and the series will

close with an account of the rise of the earliest civilizations, coming into touch with modern times in the life of the Nile Valley.

In all cases the lectures will be given by leading European and American investigators, whose personal researches have contributed largely toward the development of the fields of science which they represent. Every effort will be made to secure continuity and homogeneity of treatment, in order that the published lectures may unite into an adequate and well-balanced description of evolution in the broadest sense. The lecturers chosen will be able to eliminate unessential technicalities and to present their subjects clearly and intelligibly to general audiences. The series on Evolution should therefore appeal to a large public, interested in the broader aspects of science, but not necessarily familiar with its special methods or technical details.

The lectures will be open to the public without charge, and a cordial invitation is extended to all who may wish to attend them.

ARTHUR L. DAY,
Home Secretary

SMITHSONIAN INSTITUTION,
WASHINGTON, D. C.

THE AMERICAN PHYSICAL SOCIETY

A REGULAR meeting of the Physical Society will be held at the Bureau of Standards, Washington, on April 24 and 25. Morning sessions will begin at 9:30.

Attention is directed to the following special features of the coming meeting:

1. The members of the Physical Society are invited by the National Academy of Sciences to attend the William Ellery Hale lectures by Sir Ernest Rutherford, F.R.S., upon "The Constitution of Matter and the Evolution of the Elements" (illustrated). The lectures are two in number, and are delivered in the auditorium of the National Museum on April 21, and April 23, at 4:00 P. M.

2. A special attraction will be the exhibit of apparatus arranged by a local committee of the Physical Society. Thus far entries have been received from more than thirty manufacturers, importers and industrial research estab-

lishments. University laboratories and federal scientific bureaus will be well represented, so that an eminently successful exhibit is assured.

3. A lecture by Sir Ernest Rutherford will be given Friday afternoon at 3:30, "On X-ray and Gamma-ray Spectra" (at the Bureau of Standards?).

4. The three sessions of the meeting for the reading of papers will be joint sessions with the Electrophysics section of the American Institute of Electrical Engineers. (The morning sessions will be in charge of the Physical Society and the Friday evening session in charge of the A. I. E. E.)

5. Another feature will be the opening of the newly-completed electrical building of the Bureau of Standards. The apparatus exhibit will be there installed.

6. Members of the Physical Society and others in attendance will be guests of the scientific staff of the Bureau of Standards at luncheon in the west laboratory, at 1:00 P. M., on the days of the meeting.

7. Saturday afternoon there will be an opportunity to visit points of interest in the city, under the guidance of local members of the A. I. E. E. It is possible also that another session will be provided for the reading of papers, in view of the unusual number of titles presented.

A. D. COLE,
Secretary

THE AMERICAN JOURNAL OF BOTANY

At the Atlanta meeting of the Botanical Society of America, in January, 1914, plans were perfected for the publication of a new journal, known as the *American Journal of Botany*. As stated in the introductory note to No. 1, the need of increased facilities for the prompt publication of the results of botanical investigation has been keenly felt for some time, and the promptness with which this new opportunity has been taken advantage of, as indicated by the receipt of copy for the new venture, shows that the establishment of a new publication is amply justified.

An agreement has been entered into between

the Botanical Society of America and the Brooklyn Botanic Garden for cooperation in the publication of this *Journal*. By the terms of this agreement, which has been entered into for a period of three years, financial responsibility is assumed jointly by the Botanical Society of America and the Brooklyn Botanic Garden. The Garden names the business manager and one member of the editorial board, and the Botanical Society of America elects the editor-in-chief and four other members of the editorial board.

The *Journal* is the official publication of the Botanical Society of America, and business offices are maintained at the Brooklyn Botanic Garden and at 41 North Queen Street, Lancaster, Pa.

It is the plan for the present to include contributions to all branches of botanical science, and longer papers will be especially welcome. It is not the present plan to include reviews of literature. Each issue will consist of about fifty pages, and contributions will be welcome from all botanists. There will be ten numbers to a volume.

All correspondence with reference to prospectus, subscriptions, advertisements, and exchanges with other publications, should be addressed to American Journal of Botany, Brooklyn Botanic Garden, Brooklyn, N. Y., and correspondence concerning editorial matters and all manuscript submitted for publication should be addressed to the editor-in-chief, Professor F. C. Newcombe, Geddes Heights, Ann Arbor, Michigan. The other members of the editorial board for 1914 are C. Stuart Gager, business manager, Brooklyn Botanic Garden; Robert A. Harper, Columbia University; Duncan S. Johnson, Johns Hopkins University; L. R. Jones, University of Wisconsin; George T. Moore, Missouri Botanical Garden; and Edgar W. Oliver, Brooklyn Botanic Garden.

THE CANADIAN ENTOMOLOGICAL SERVICE

THIRTY years ago, in 1884, the Canadian government appointed a Dominion entomologist to advise agriculturists and others regarding the control of insect pests. Two years

later on the establishment of the experimental farms system, Dr. James Fletcher, who occupied the position, was attached to the new branch of the Department of Agriculture in the joint capacity of entomologist and botanist, which position he occupied with conspicuous success until his death in 1908. The growth in importance of the subjects necessitated their separation and accordingly divisions of entomology and botany were created. Dr. C. Gordon Hewitt was appointed Dominion entomologist in 1909 and entrusted with the work of organizing the new division of entomology of the experimental farms branch of the Department of Agriculture, with offices and laboratory at the Central Experimental Farm, Ottawa.

The urgent need of legislation in order to permit action to be taken to prevent the introduction into Canada and spread within the country of serious insect pests and plant disease was responsible for the passage of the Destructive Insect and Pest Act in 1910. The still greater need of investigations on the insect pests affecting agriculture, forestry and other branches of human activity has led to the establishment of field or regional laboratories in different parts of Canada with trained entomologists in charge to study local problems.

Owing to the consequent expansion of the entomological work along investigatory and administrative lines and the fact that such work did not constitute a necessary part of the work of the experimental farms system and executive was virtually distinct, the entomological service has now been separated from the experimental farms branch and has been constituted an independent branch of the Department of Agriculture under the direction of the Dominion entomologist. It is proposed to erect a building to provide offices and laboratories for the new entomological branch. Will correspondents kindly note that all official communications and publications should be addressed to "The Dominion Entomologist, Department of Agriculture, Ottawa."

This reorganization, which will also include the establishment of a national collection of

the insects of Canada in the Canadian National Museum (The Victoria Memorial Museum) at Ottawa under the care of the Dominion entomologist, marks an important step in Canadian entomology. It will result in a still greater development of the study of Canadian insects along scientific and practical lines.

SCIENTIFIC NOTES AND NEWS

At the meeting of the American Philosophical Society to be held at Philadelphia on April 23, 24 and 25, a large and important program of scientific papers will be presented. An account of the meeting with abstracts of the papers will be published in *SCIENCE*.

MR. F. W. HODGE, of the Bureau of American Ethnology, has been elected an honorary member of the Sociedad Científica Antonio Alzate of the City of Mexico.

PROFESSOR LAWRENCE MARTIN, of the University of Wisconsin, has been elected a corresponding member of the Kaiserlich-Königliche Geographische Gesellschaft in Vienna.

THE Austrian Zoological and Botanical Society has awarded the Archduke Rainer gold medals to two members of Yale University, Dr. Ross G. Harrison, Bronson professor of comparative anatomy, and Dr. George R. Wieland, lecturer in paleobotany.

THE British Local Government Board has authorized the following special researches, to be paid for out of the annual grant in aid of scientific investigations concerning the causes and processes of disease:

1. An investigation by Dr. Eardley Holland into the causes of stillbirths.
2. A continuation of the Board's inquiry into the cellular contents of milk by Professor Sims Woodhead.
3. A continuation of the Board's inquiry into the causes of premature arterial degeneration by Dr. F. W. Andrewes.
4. An investigation by Dr. M. H. Gordon and Dr. A. E. Gow into the etiology of epidemic diarrhoea in children.

THE council of the Royal Geographical Society has decided to award their royal medals and other honors for the present year as fol-

lows: Founder's medal, Professor Albrecht Penck, professor of geography at Berlin and director of the Oceanographical Institute; Patron's medal, Dr. Hamilton Rice, of Boston, Mass., known for his explorations of the region of South America drained by the headwaters of the Orinoco and of the northern branches of the Amazon; Murchison grant, Commander H. L. L. Pennell, R.N., a member of the Antarctic expedition of 1910, and selected by Captain Scott to command the *Terra Nova* after the landing of the shore parties; Gill memorial, Mr. A. E. R. Wollaston, who has made extensive journeys in many parts of the world, chiefly for zoological work; Cuthbert Peck grant, Dr. J. Ball, employed in the geological survey of Egypt for the past eighteen years; Back grant, Mr. J. N. Dracopouli, known for his work in the Sonora desert of Mexico and for his expedition to the Lorian Swamp.

THE former students of Dr. J. McKeen Cattell, professor of psychology in Columbia University, at a dinner held in New York on April 8, presented him, in celebration of his completion of twenty-five years as professor of psychology, with a "Festschrift" in the form of reviews of his researches and of work in psychology to which they have led. The contents of the volume are:

"Work on Reaction Time," by V. A. C. Henmon.

"Studies of Reading and Perception," by Walter F. Dearborn.

"The Association Method," by F. Lyman Wells.

"Psychophysical Contributions," by R. S. Woodworth.

"Studies by the Method of Relative Position," by H. L. Hollingworth.

"The Study of Individual Differences," by E. L. Thorndike.

On April 6, 7 and 8, there was held at Columbia University a Conference on Individual Psychology by former students of the department of psychology, at which thirty papers were presented.

DR. M. MIYOSHI, professor of botany in the Imperial University of Tokyo, is visiting the scientific institutions of the United States.

PRINCETON UNIVERSITY has granted leaves of absence for the academic year 1914-15 to Professor H. D. Thompson, of the department of mathematics; and to Philip E. Robinson, assistant professor of the department of physics.

THE American Association of Pathologists and Bacteriologists met in Toronto, on April 10 and 11, under the presidency of Professor J. J. McKenzie, of Toronto University. There also met at Toronto the International Association of Medical Museums, with Professor R. M. Pearce, of Philadelphia, as president, and the American Association for Cancer Research, under the presidency of Dr. Ernest E. Tyzzer, of the Harvard Medical School.

MR. F. J. NORTH, assistant in the geological laboratory, King's College, London, has been appointed assistant keeper in the department of geology in the National Museum of Wales.

PROFESSOR M. FRÉCHET, of the University of Poitiers, will give at the University of Illinois during the academic year 1914-15 a course of lectures on general analysis.

INDIANA UNIVERSITY will hold, on April 16 and 17, a conference on educational measurements. The principal speaker is Professor E. L. Thorndike, of Teachers College, Columbia University.

DR. JOHN A. BRASHEAR, of Pittsburgh, recently delivered two illustrated lectures at the University of Illinois on "The Contribution of Photography to our Knowledge of the Stellar Universe," and "Engineering Problems in the Construction of Large Telescopes." The lecture on celestial photography was held in the university auditorium with an audience of fifteen hundred persons.

DR. L. A. BAUER gave on April 3, in the Engineering Societies Building, the evening lecture at the first joint meeting of the American Geographical Society and of the Association of American Geographers, his subject being "The General Magnetic Survey of the Earth," illustrated by lantern slides of the work of the *Carnegie*, and of the various expeditions to more or less unexplored countries.

THE annual John Lewis Russell lecture of the Massachusetts Horticultural Society was delivered on March 21, by Dr. Perley Spaulding, pathological inspector of the Horticultural Board of the U. S. Department of Agriculture. The subject was "Undesirable Foreign Plant Diseases."

DR. M. W. TWITCHELL, the assistant geologist of New Jersey, lectured before the department of geology of Princeton University on March 16, 20, 23, 27 and 30, the general subject of the series being "The Geology of New Jersey."

PROFESSOR GEORGE GRANT MACCURDY, of Yale University, gave two lectures at Rutgers College on March 25 and 26, one before the New Jersey State Microscopical Society on "Primeval Man," the other before the Phi Beta Kappa Society on "The Dawn of Art."

PROFESSOR SAMUEL W. WILLISTON addressed the Chicago chapter of the Sigma Xi at its regular winter quarter meeting, on March 11, on the topic: "Recent Discoveries Relative to the Early Land Life of North America."

ON March 28, Professor C. H. Shattuck, of the Forestry Department of the University of Idaho, delivered a lecture before the Puget Sound Branch of the American Chemical Society on "Wood Processing."

DR. ALEXANDER F. CHAMBERLAIN, professor of anthropology at Clark University, died on April 8, at the age of forty-eight years.

DR. JOSEPH D. BRYANT, professor of surgery in the University and Bellevue Hospital Medical College, died in New York on April 8, aged sixty-nine years.

DR. ALFRED CONOR, vice director of the Pasteur Institute at Tunis, has died from infection contracted in his experimental work.

THE U. S. Civil Service Commission announces an examination for mining engineer in the Bureau of Mines, Department of the Interior, for service in the field, in relation to coal mining or metal mining, at salaries ranging from \$2,400 to \$4,000 a year. For the same bureau there will be held examinations for mine statistician and for assistant-engineer

of mine tests at Pittsburgh at salaries ranging from \$1,800 to \$2,400.

MR. ANDREW CARNEGIE has given \$100,000 to the New York Zoological Society to provide a pension fund for the New York Zoological Park and the Aquarium. The scientific staff and the employees will contribute annually 2 per cent. of their salaries, and any sum that may be lacking will be made up by the Zoological Society.

THE Rockefeller Institute for Medical Research, New York, announces that it has received from Mr. John D. Rockefeller an additional endowment of \$1,000,000 for the purpose of organizing a department for the study of animal diseases. A gift of \$50,000 has also been received from Mr. James J. Hill, for the study of hog cholera. The announcement says: "It is the expectation of the trustees of the institute that the new department by making possible a very thorough and exhaustive study of animal diseases by trained experts will prove a great boon to raisers of cattle, hogs, sheep, and other animals, as the opinion has been expressed that many of the diseases could be held in check and perhaps practically stamped out if the breeders had practical knowledge on which to act. With the present facilities at hand, the income from the \$1,000,000 endowment will make it possible to carry on the work on a broad scope at once."

THE department of terrestrial magnetism of the Carnegie Institution of Washington, founded on April 1, 1904, is now occupying its new building, which has been especially erected, at 36th Street and Broad Branch Road, Washington, D. C., to provide the requisite facilities for the varied research work of the department, both along experimental and observational lines.

SIR ERNEST SHACKLETON has bought the ship *Polaris*, now at Sandefjord, to be his "flagship" on his forthcoming Antarctic expedition.

THE Swedish government has appropriated \$13,500 for traveling expenses to be dis-

tributed among Swedish engineers who desire to visit the Panama-Pacific Exposition in San Francisco in 1915.

THE fiftieth meeting of the New England Association of Chemistry Teachers will be held in Boston on Saturday, April 25, 1914. The morning session will be devoted to the past, present and future of the association. Past presidents will speak, and the history of the association will be read. A complimentary luncheon will follow. It is hoped that the afternoon session will include a moving picture exhibition of chemical industries. In the evening there will be a reception and collation, followed by speaking, at the Copley Plaza.

THE twenty-fifth session of the Biological Laboratory of the Brooklyn Institute of Arts and Sciences, located at Cold Spring Harbor, Long Island, will be held from June to September. The regular class work will begin Wednesday, July first, and will continue for six weeks, to August 12. The instruction offered includes a course in field zoology by Dr. H. E. Walter, of Brown University, assisted by Dr. S. I. Kornhauser; in bird study by Mrs. H. E. Walter; in comparative anatomy by Professor H. S. Pratt, of Haverford, and Dr. D. D. Whitney, of Wesleyan University; in animal bionomics and evolution by Dr. C. B. Davenport; cryptogamic botany by Professor H. H. York, of Brown University, and Dr. W. E. Maneval; systematic and field botany by Professor John W. Harshberger, of the University of Pennsylvania. Opportunities are also offered for investigation in zoology and botany. A training course for field workers in eugenics is given under the direction of Dr. C. B. Davenport and Mr. H. H. Laughlin. The complete announcement may be got by addressing the Biological Laboratory, Cold Spring Harbor, N. Y.

THERE are now being assembled in the United States National Museum, the bones of a very small three-horned dinosaur which is being made the type of a new species. This diminutive dinosaur, when completely assembled, will measure about six feet in length and stand only about three feet high. Its head

is twenty-two inches long. When its bones are compared with those of the larger members of this extraordinary family of reptiles, it will be seen that this specimen is less than one fourth of their size. In the National Museum are several skulls of one of the large horned dinosaurs, *Triceratops*, which measure from six to eight feet, and in one case, nine feet. The group to which this new member belongs is called the *Ceratopsia*, from the horns which adorn their heads; two above the eyes and one on the end of the nose. Unlike the others, this species has small and not prominent horns over the eyes, while the nasal horn is an outgrowth of the nasal bone and not an additional growth, as is the case with the others. Another peculiarity is that this horn is split lengthwise in such a manner that one side has the appearance of having slipped by the other. Its jaws are like those of a turtle, there being no front teeth but a sharp curved beak. Farther back in the jaws, however, are very finely sculptured cutting teeth, which show the animal to have been herbivorous. Like the other members of this group, it has a deep collar known as a frill, but in this species it has an open space on either side of the neck. The frill was covered with horn and formed a defensive armor for the protection of the neck. This particular specimen was found with the foot and tail articulated, which makes it especially interesting as being the first complete and connected specimen ever obtained. The foot has four toes, the first with two bones, the second with three, the fourth with five, while only a trace of the fifth toe remains, tending to show the loss of that member through disuse, as is the case with the horse. Parts of the other feet are also in this collection, as well as nearly all the bones of one individual. In the whole specimen there are but few bones and parts which will have to be restored. Considering that the first specimens of this family were discovered some forty years ago, it is curious that this small individual is the most complete one that has been found. These fossils were found by Mr. Charles W. Gilmore during the summer of 1913, while he was working for the Geological

Survey in the Blackfeet Reservation in northwestern Montana. The partial skeletons of five individuals were uncovered at the same time and form a most valuable addition to science. Mr. Gilmore has written a preliminary paper on the new species, published in the Smithsonian Miscellaneous Collections, and is working on the assembling of the specimens for exhibition in the National Museum.

CALIFORNIA state inspectors at San Francisco have found a new canker disease on chestnut trees recently imported from Japan. According to Dr. Haven Metcalf, the government's expert on such diseases, this appears to be of the same type as the chestnut blight which is ravaging the forests of the eastern United States, and it is possible that the new disease would be equally destructive if it became established in this country.

UNIVERSITY AND EDUCATIONAL NEWS

THE General Education Board has promised to give \$750,000 to Wellesley on condition that the balance of the \$2,000,000 restoration and endowment fund is completed by January 1, 1915.

It is said that one million dollars will be received by the University of Pennsylvania from the estate of Dr. Louis A. Duhring, for many years professor of dermatology. At the time of his death on May 8, 1913, his bequest was estimated at only \$400,000.

GRINNELL COLLEGE has completed its \$500,000 endowment fund. Of this sum \$100,000 was given by the General Education Board and the rest was raised by the college. The productive funds of the college now total more than \$1,300,000. Of the amount just secured, \$150,000 is to be devoted to the erection of new buildings.

THE managers of the Presbyterian Hospital, New York, have taken action reorganizing the administration of the scientific and therapeutic work at the hospital so as to provide for single responsibility for both the medical and the surgical services. Dr. Theodore C. Janeway, Bard professor of the practise of medicine in the College of Physicians and Sur-

geons, Columbia University, has been designated medical director of the hospital, and Dr. George E. Brewer, professor of surgery, has been designated surgical director. Dr. William G. MacCallum, professor of pathology, has been appointed pathologist at the Hospital.

PROFESSOR ALAN W. C. MENZIES, Ph.D., now head of the department of chemistry at Oberlin College, has been elected professor of chemistry at Princeton University. Other changes are Dr. Edward Gleason Spaulding, promoted to a full professorship in philosophy; and Dr. Thomas Hakon Gronwall, elected assistant professor and preceptor in mathematics.

RECENT promotions in the faculties of the University of Chicago include the following: To professorships: Harlan H. Barrows, geography; and Ernest J. Wilczynski, mathematics. To associate professorships: Elliot R. Downing, natural science (College of Education); Albert Johannsen, petrology; Walter S. Tower, geography. To assistant professorships: Storrs B. Barrett, Yerkes Observatory; Albert D. Brokaw, mineralogy and economic geology; Rollin T. Chamberlin, geology; and Arno B. Luckhardt, physiology. The new appointments include that of Oliver J. Lee to an instructorship in astronomy.

JAMES WITHEYCOMBE has resigned his position as director of the Oregon Agricultural College Experiment Station.

DR. WILLIAM E. HOCKING, professor of philosophy in the University, has accepted a chair of philosophy in Harvard University.

MR. G. H. HARDY, M.A., fellow of Trinity College, University of Cambridge, has been appointed to be Cayley lecturer in mathematics, and Mr. A. Berry, M.A., fellow of King's College, a university lecturer in mathematics.

DISCUSSION AND CORRESPONDENCE

MINERAL NOMENCLATURE

THE need for revision of mineral nomenclature has been recently emphasized by Professor Austin F. Rogers, of Stanford University.¹ While I agree in the main with the

¹ *Proc. Amer. Phil. Soc.*, 52, 606-615, 1913.

views he expresses, it seems to me that his plan of treatment of isomorphous series is likely to complicate rather than simplify matters. Professor Rogers proposes that minerals be named by the predominant molecule of the isomorphous series, that isomorphous admixtures be indicated by adjectives, and that chemical prefixes be restricted to artificial substances. It would appear to me preferable to have mineral names apply to the isomorphous series as a whole, and, in most cases, to use chemical prefixes for end-members of series, whenever it is desired to discuss their relations.

The difference between these methods can best be brought out by citing a few examples. For instance, according to Rogers' plan the term carnotite would apply only to a (theoretical) potassium end-member of the isomorphous series of double uranyl vanadates, tyuyamunitite to the calcium end-member. Specimens in which both are present would have to be called calciferous carnotite, if potassium predominated, and kaliferous tyuyamunitite if calcium predominated, and indeed an analysis would be necessary before the material could be correctly named at all. According to my plan the name carnotite would apply to the isomorphous series itself, and could then continue to be used by laymen—miners, dealers, newspaper writers—to whom the exact composition is of no significance, to describe any sample of the mineral; while the compound names calcio- and kalio-carnotite would be used by the specialist discussing the composition of a given specimen, or its relations with other minerals.

The first plan would also do away with a number of well-known, useful, mineral names—with axinite, columbite and wolframite for instance, because they are made up of iron and manganese end-members—and, in general, with every name of a mineral as soon as it is discovered to be an isomorphous mixture. It would further require the introduction of two new names, for the end-members, in most cases. According to the second, on the other hand, advance of knowledge would not necessitate either the discarding of estab-

lished names, nor the introduction of wholly distinct, independent, arbitrary ones, but only the addition of appropriate chemical prefixes, yielding ferro- and mangano-axinite, ferro- and mangano-columbite, etc. Some of these compound names have already been introduced, and have proved very useful in discussions of the relationships of the minerals; and they can cause no ambiguity so long as it is definitely understood that they apply to end-members of series only. Natronorthoclase in the sense of orthoclase containing sodium replacing part of the potassium, cobaltcalcite in that of calcite containing a little cobalt, etc., would, however, have to be dropped (as also recommended by Rogers).

In the few cases where the end-members of a series are common, well-known and well-characterized minerals, convenience may demand that independent names be retained as synonyms of these compound ones. Thus while wolframite remains the name for the isomorphous mixtures of iron and manganese tungstates, ferberite and hübnerite may at times be used instead of ferro- and mangano-wolframite, since they are sufficiently characteristic to be recognized by miners, dealers and beginning students. Yet I have found that practically every mineralogist, when asked what ferberite is, will reply "wolframite high in iron" rather than "iron tungstate." So, even if the distinct names are retained in this case the compound chemical ones had better be used synonymously with them.

My suggestions are then, in short, that when a mineral is discovered to be an isomorphous mixture of two (or more) components the species name shall be regarded as a group name, representing any and all members of the series; that the end-members in general shall be designated by chemical prefixes applied to the species name; but that if the end-members are so distinct, characteristic and well known that they can be thought of independently, and already have separate names, that these names be retained as synonyms of the compound, chemical, ones. If this plan should be systematically applied it would simplify mineral nomenclature with a minimum of

change from existing conditions, apparently a highly desirable result. EDGAR T. WHERRY

NATIONAL MUSEUM,
WASHINGTON, D. C.

THE WELLESLEY FIRE

TO THE EDITOR OF SCIENCE: The article of Professor Caroline B. Thompson entitled "The Wellesley Fire" stated that "the more important losses to physics are lantern slides, a collection of crystals, a unique collection of Nicol prisms. . . ." The lantern slides, although a useful adjunct to the apparatus, represented an inconsiderable part of the total loss. It is true that it will be difficult to duplicate the larger crystal sections and that the Nicol prisms, although by no means forming a "unique collection," were unusually good for a college of liberal arts as indeed was the entire equipment.

In a loss amounting in the aggregate to many thousands of dollars it is idle to enumerate particular items, but it may be noted that the department was especially fortunate in its equipment for the study of advanced optics and electricity. The apparatus included a commercial photometer, a large optical bench for the study of interference and diffraction effects, a Michelson interferometer, Lummer plate spectroscope, polariscopes, polarizing microscopes, Frick polarimeter, apparatus for the Zeeman effect, etc. Recently considerable time had been devoted to developing an experimental lecture course in "Electric Oscillations." To bring the equipment again to the same degree of efficiency will be the work of years.

LOUISE SHERWOOD McDOWELL
WELLESLEY COLLEGE

SCIENTIFIC BOOKS

Across Unknown South America. By HENRY SAVAGE-LANDOR. Two volumes. Boston, Little, Brown & Company. 1913. Pp. xxiii + 377 and xvi + 439, illustrated.

A map given at the end of the first volume shows that the author traveled extensively in various parts of South America, but it is not clear which part of that continent he regards as unknown. From Rio he went to S. Paulo, and thence to Araguay in western Minas by

railway. From there to the city of Goyaz he traveled a much used road. From Goyaz he went westward on the road leading to Cuyabá. That road is not only much traveled and well known, but is shown on most maps of Brazil, such as Stieler's hand atlas and Baron Homem de Mello's atlases of Brazil, 1882 and 1909. There is even a telegraph line connecting the city of Goyaz with the city of Cuyabá. Francis de Castelnau made the trip in 1844, and his account of it is given in detail in the second volume of his "Expedition dans les parties centrales de l'Amérique du Sud," pages 218-282.

At Capim Branco, near Cuyabá, the author abandoned the main road and struck out across country by compass. The various disagreeable experiences off the main road were such as one would naturally expect, whether traveling in the interior of Brazil or in the interior of Pennsylvania. Little wonder that his men objected. This wandering about through the woods seems to have been regarded as exploration of an unknown region, though it is to be noted that he found farmers living there, and that the names of the streams were known to his companions.

After a few days in this "unknown" region he came out in the road leading from Rosario to Diamantino, and near the latter place took a canoe, without the necessary outfit, and descended the Arinos and Tapajos.

Here again he seems to regard the region as unknown. But the Arinos and Tapajos, in spite of their many and difficult falls and rapids, have been navigated constantly for more than a hundred and fifty years. Father Ayres de Cazol in his "Corografia Brazilica," published at Rio in 1817, says (Vol. I, p. 261) that in 1747 Captain João de Souza descended to Pará by way of Rios Arinos, Tapajos and Maranhão, and returned by way of the Madeira with canoes laden with European goods.

Dr. Mello Moraes in his "Corografia historica do Imperio do Brasil," Rio, 1859, 486, speaks of the voyage of João de Souza in 1747, but adds that Leonardo de Oliveira descended that river in August, 1742.

Joaquim Ferreira Moutinho, author of "Notícia sobre a provincia de Matto Grosso," S. Paulo, 1869, in speaking of the guaraná trade in Matto Grosso, says (p. 212) that the great consumption of this article keeps up the trips to Pará by way of the rivers Preto, Arinos, etc. This author speaks at length of the trips on the Arinos and Tapajos and gives the distances between the principal falls, and adds that the trip to Pará is made nowadays much more easily than formerly on account of the experience of the pilots and canoemen (p. 216).

Dr. Severiano da Fonseca in his "Viagem ao redor do Brasil," I., 75-79, tells of various trips up and down the Arinos and Tapajos, and gives the distances between various points.

In 1827 G. H. von Langsdorff, the well-known traveler, then Russian consul-general to Brazil, made a trip down the Arinos and Tapajos. There is a brief account of it in the "Revista do Instituto Historico do Brazil," Vol. XXXVIII., 348-349.

The writer of this review went to Diamantino in 1882 with the purpose of descending the Arinos and Tapajos to Santarem. There was a regular traffic on the river, and during his short stay at Diamantino a canoe loaded with guaraná arrived from the lower river. The voyage was not made, however, for the simple reason that the canoemen were in debt at Diamantino, and their creditors would not allow them to leave unless their debts, amounting to several thousand dollars, were paid.

If it is too much to expect that the writer of such a book should take the trouble to acquaint himself with the older literature of the subject, surely it is not unreasonable to expect him to look through the indexes of the Royal Geographical Society of London in order to find out whether the region he traversed was unknown. Volume thirty-two of the *Journal* of that society, pages 268-280, contains an account by Chandless of his trip down that river more than fifty years ago, together with his determinations of latitudes and longitudes.

Inasmuch as but little is known of the details of the geology of the region between Goyaz and Cuyabá, the reviewer was much interested at first in the lava flows, ashes, volcanoes and craters reported across Goyaz and Matto Grosso (pages 171-291). These phenomena were quite unexpected, and their mention on almost every page led to suspicion first, and later to a comparison with the notes of the trip across the same region made by Castelnau in 1844. Evidently the author mistook for volcanic phenomena the iron cemented rocks known in Brazil as *canga*. The book fairly swarms with such absurdities and half truths.

Pages 181 to 230 of volume I. are devoted to the Bororó Indians, their customs and legends. One is amazed at the great amount of material gathered by a person who knew nothing of the language. The length of his stay among them is not definitely given, but he left them before May 20 (p. 233), and as he had entered Matto Grosso May 11, it is clear that he was with the Bororós less than a week.

The trip down the Arinos and Tapajos was one long series of difficulties in passing falls and trouble with his men. On the lower Tapajos he left the river and struck out afoot through the forests, and, as one would expect, he was soon in trouble again with his men, and out of food in addition to the inconveniences naturally to be expected in such a region.

From a scientific point of view such a book is not worthy of review space. The cosmic and ethnologic theories propounded in the preface, and the evidence on almost every page of untrustworthiness of statement put it quite out of the rank of books that can be regarded as contributing to any branch of science. It is a great pity that so much energy and money should have been expended to such little purpose.

By his own confession he could not control his men, and the reader is constantly wondering how long such an expedition can hold together, and whether the author will starve to

death or get drowned or killed right away or a little later on.

That he underwent great inconveniences and sufferings goes without saying. Such a trip can not be made in a tropical country without them; but it is questionable whether readers should be bothered with his mosquitoes, his ants, his cattle ticks, and his run-away mules.

The photographs are the one redeeming feature of the book. J. C. BRANNER

A Text-book on the Teaching of Arithmetic.

By A. W. STAMPER. New York, American Book Co. Pp. 1+284, including bibliography and index.

This book is a real contribution to pedagogy, for although its author disavows novelty in theory and completeness in scope, he has come nearer to writing a text-book in the teaching of arithmetic for beginners than has any other writer. It differs from the other excellent works on the same subject, such as those listed in the author's bibliography, in that it gives more space to instruction in the details of method and in class-room practise than to inspirational matter. It summarizes and applies the results of pedagogical research instead of dwelling upon their origin. In comparison with other books on the teaching of arithmetic, it is a manual of method rather than a reference book for the teacher's professional library.

As to its fitness for this purpose, it covers well the courses in the teaching of arithmetic given in our better normal schools. It is a well-rounded and well-balanced treatment of school. It is in general accurate as to fact, and sound in doctrine. The author has profited by his labors at Teachers College, Columbia University, particularly by his access to the great collection of original arithmetical works gathered there. These sources, supplemented by the accurate digests and classifications, and the collections of related mathematical apparatus, constitute the most significant assemblage of historical material on the subject of arithmetic to be found anywhere in the world.

But with all this the book is a chart of the

beaten path. It will serve to help the laggards rather than to blaze a new trail. To some the book will seem to be written wrong end to. As it stands the order of discussion is: Origin (Chap. I.), Logic (Chap. II.), Subject Matter (Chaps. III.-VI.), Method (Chaps. VIII.-X.), Purpose (Chap. XI.). But among these topics why should not the last be first? The author makes aim or purpose the first consideration in his typical method lessons, and states (pp. 248-249) the controlling aim in the teaching of arithmetic. If the discussion of the selection, presentation and study of subject matter had been controlled from the start by the real purpose, it would not have greatly modified the conclusions of this volume. But it would have thrown a flood of light on why we are told to teach or not to teach certain things, and why we are told to teach in a prescribed way. The subject, if approached from this stand-point, would necessitate discussing, to a greater extent than the author does, the attitude of the pupil, who, after all, is the first consideration, the chief beneficiary and the sole legatee in the teaching of arithmetic.

The following more specific references may be of value: Pp. 9-18: A pragmatic treatment such as indicated above would relegate these meager nine pages of history to subordinate notes under related topics in later chapters. P. 18, questions 5 and 6, are of little value. P. 20: The *working* definitions explained at the bottom of the page should be emphasized as the kind of most value in arithmetic. P. 29: It would help the teacher, if the author had admitted that counting is measuring in the broadest sense. P. 30: the last paragraph could be strengthened thus: To the statement, "The multiplicand and the product being concrete," add "and of the same kind." Also to the statement, "The dividend is always concrete," should be added, "if either of the other terms are." P. 43: Young teachers may be led to overvalue work in artificial scales. P. 44: The expression, "When the first nine," would better be "when the column at the left." P. 51: The teaching of casting out nines is of doubtful value as a practical check required in the universal course of study. P. 58: Re-

mainders should be taught before formal division. Thus, when the pupil knows that four sevens are twenty-eight, he should learn that thirty is four sevens and two units remaining. P. 63: The Euclidean method of greatest common divisor is referred to without explanation. P. 74, last paragraph of the example: The reason "Since we get the same answer . . ." is not sufficient and is inexcusable because the real reason is so apparent. In the process of reducing the fractions to their common denominators the numbers 8 and 9 are actually found thus, 4×2 , 3×3 . P. 99: This is too advanced to be of practical value in the grades. P. 101, last paragraph: Although the author has good precedent for this, it is surely a perversion to teach that "hundredths" and "per cent." are interchangeable. For if so, then 7.07 per cent. could read seven and seven per cent. per cent., an unfortunate confusion. Per cent. is primarily a rate per hundred, and its presentation as such would not exclude the desirable things in the author's subsequent treatment. P. 110 (a): "Times greater than" is a loose use of language for "times as great," probably due to the author's effort to carry out an analogy to percentage. Pp. 109-111: This correspondence between percentage and the processes with integers and fractions is not sufficiently significant to warrant its use in the class-room, and is of little value to the teacher. Pp. 126-135: The explanations on these pages are rather complicated, and, taken as a whole, are not teachable in the class-room. It would be better to point out for the teacher exactly the form to be used. Pp. 148-152: One is disappointed not to find a reference to the modern partial-payment problem most frequently met; namely, the one in which limited payments are accepted at stated intervals, usually at interest dates. Pp. 180-181: An expansion and illustration of this topic would be of greater value than the familiar material on pp. 172-175. Chapters VIII.-IX., pp. 196-233, are Herbartian and discuss the teaching process from the standpoint of the subject, instead of from the standpoint of the pupil. Pp. 200-201: The teacher's aim is relatively unimportant. It is the pupil's purpose that controls

his activity. Consequently he must have a stronger motive than that suggested at the end of p. 201. In this connection, compare pp. 201 and 203 with the more helpful suggestions on pp. 212 and 218. Pp. 236-242: these lists impress one as more complete than significant. The points made need classifying. The young teacher should be told which of these are most important. It is better to study a few essentials of a model lesson, than to attempt so ambitious a list. Pp. 243-277: Chapter XI. is wholly inadequate, especially in its treatment of the curriculum. The vital question to-day is not, "How shall we parcel out the body of arithmetical science?" but, "What live issues, appreciated by children, shall we choose as the core of instruction?" The curriculum must precede method, hence the prospective teacher should be instructed to observe this order in teaching. Pp. 278-280: Since many of our normal students take one or two modern languages, a few references to foreign works on the teaching of arithmetic might be helpful, particularly the German works of Unger and Knilling.

The foregoing criticisms should not be taken as the estimate of the book. The volume is packed with good suggestions to teachers, and will take its place among the most useful half-dozen available books on the subject.

LAMBERT L. JACKSON

MONTCLAIR, N. J.,

January 3, 1914

Guide to the Study of Animal Ecology. By CHAS. C. ADAMS. New York, Macmillan. 183 pages.

This book is essentially a bibliographical and methodological manual for field students in ecology. As is stated in the preface the primary emphasis is upon ecological survey work. Thus instrumental measurement of the environment and experimental study are elaborated in the literature cited. The following chapter headings appear: Aim, Content and Point of View; The Value and Method of Ecological Surveys; Field Study; The Collection, Preservation and Determination of Specimens; Scientific Technique; Sources of Information on

Life Histories; Environmental Change; Metabolism, Growth, etc.; Adjustment between the Environment and Animal. Its scientific value lies in the author's outline for the organization of the science.

In the first chapter, the subject is divided into "individual ecology" or the ecology of individuals and species, and "aggregate ecology," or the ecology of taxonomic groups of species, genera, families, etc. These two divisions have usually not been recognized separately. The distinction is good, but the two divisions taken together are coordinate with his third division, "associational ecology," or the ecology of communities. Chapters II-IV. are devoted to ecological surveys and methods of conducting them. The author rightly deplors the tendency of museums to rate the work of collectors and expeditions on the basis of number of specimens brought back, as this discourages the recording of ecological facts. The methods of collecting, preserving and arranging notes and specimens, and securing proper identification of the latter are given. These chapters will be of material aid to those undertaking field ecological study.

Although divided under several chapter headings, the remainder of the book consists essentially of about 90 pages of classified bibliography. The references are of a diversified type and are intended to guide the worker to needed information, ranging from the making up of the sometimes necessary camping outfit, to the preparation of his results for the printer. They are classified under general headings and many are followed by statements as to contents. Representative papers on the environment, animal communities, struggle for existence, physiology, behavior and many other topics are included. The references are complete enough to give valuable suggestions to workers from almost any point of view in ecology. The comments on the more important older ecological papers make it clear that a considerable number of incomplete attempts at organization of knowledge of animal communities have been recorded. Thus by means of the references, the

book gives the history of the development of the science.

THE "GOLDEN MEAN" IN THE INHERITANCE OF SIZE

IN bulletin 242 of the New Jersey State College Experiment Station, page 39, appears the following statement:

The size and shape of the F_1 (tomato) fruits are the geometric means between the size and shape corresponding to those factors of the parents, which were active in crossing.

This statement was based upon the measurements of many thousands of tomato fruits. A mode of inheritance in which $x(F_1) = \sqrt{ab}$ assumes that in the union of gametes representing factors for size a multiplication and the extraction of a square root take place. I was unable at the time to explain how that might occur, and so far no attempt by any one else to interpret the significance of my results has come to my notice. In a forthcoming bulletin I shall present details of F_2 and F_3 , and this paper is published solely to set forth the nature of the principle of size inheritance by the "golden mean," to indicate its bearing upon vital questions on subjects in heredity, and to establish the priority of its discovery.

When two factors for different sizes of homologous parts meet in a cross, the resulting F_1 size is commonly intermediate in such parts as are not greatly subject to fluctuation. If a and b represent the parental size characters, it has been tacitly assumed by most investigators that the F_1 size is $(a + b)/2$. In tomato fruits I found it to be \sqrt{ab} . On the face of it the average (algebraic mean) seems the more probable, but when used as the basis for the comparable inheritance of lines, surfaces, and volumes, it becomes impossible. For example, let plants be crossed, which have spherical fruits of diameters a and b , and let us assume, for the sake of simplicity, that all cells constituting the volumes of both fruits are of equal dimensions. Then the ratio between parents and F_1 of the number of cells

forming any diameter one cell in thickness would be as $a:(a+b)/2:b$; the ratio between the cells making up the surface (epidermis) of the respective fruits would be as $a^2:[(a+b)/2]^2:b^2$; while the ratio between the number of cells constituting the entire volume would be as $a^3:[(a+b)/2]^3:b^3$, all of which ratios are different. It is evident, however, that any cell might be cut by a diameter and that the surface cells are part of the volume. The size inheritance of an epidermal cell might fall under either of these three ratios, depending on which aliquot part of the fruit was under study. If there is inheritance of the nature $x=(a+b)/2$, it is not clear why the diameters and not the surfaces or volumes should fall under that principle. If one does, the other two can not.

If it be assumed, under like conditions, that $x=\sqrt{ab}$, the ratio between parents and F_1 of the number of cells forming a diameter one cell in thickness becomes $a:\sqrt{ab}:b$; that between the surface cells $a^2:ab:b^2$; and that between the total cells in the volume of the sphere $a^3:ab\sqrt{ab}:b^3$. These three ratios are all equal to $a:\sqrt{ab}:b$, if a and b mean the respective parents, so that no matter what aliquot part of the fruit is under study, the ratio of size inheritance of lines, surfaces, and volumes would be the same. Surely this appears the more probable.

But how can a plant extract the square root of a product? For the sake of convenience in demonstration let us assume that the fruits are cubes instead of spheres, that all cells are equal and of size 1, and that parental characters of size are 4 and 9. Then the length factor of the F_1 would be made up of two forces, one tending to build strings of four cells in the direction of the longitudinal axis, the other tending to build strings of nine cells. Similarly, the breadth factor would be made up of two such forces building at right angles, and in the same way the factor for thickness at right angles to both. Constituent 4 of the length factor, coming from one parent and constituent 9 of the breadth factor coming from the other parent may then be imagined as building at right angles to each other, in strings of nine in one direction, in strings of

four in the other. The respective partners of the two factors would be similarly engaged, and likewise the two length factors with those for thickness and the two breadth factors with those for thickness. Each set of two would tend to build rectangles of the dimensions $9 \times 4 = 36$. If now there were some force stronger than the tendency of the size factors, which would prevent the formation of rectangles and permit only squares, while having no influence on absolute size, area, or volume, the sets of size factors would be forced to modify the shape of their structures, making squares instead of rectangles. Since the modifying force did not influence area, the resulting squares would also be of the area 36, their sides 6, and the cubical fruits $6 \times 6 \times 6 = 216$. This modifier of size is the factor for shape. When both parents carry only the factor for cubical shape, the F_1 fruits are cubical, no matter what the tendencies of the size factors.

In spheres the diameters are directly proportional to the sides of equal cubes; so that what applies to cubes in this respect, applies to spheres as well. The factor for spherical shape is the modifier of the interaction of the factors for absolute size.

At first sight it may seem as if the fact that the size of the F_1 is the golden mean between the parental sizes can be of little value beyond furnishing an explanation of partial dominance in the F_1 . However, the recurrence of the action of the modifier (shape) upon the various size combinations in the F_2 interferes greatly with the chances for the appearance of certain visible size characters.

We know that size characters do segregate in the F_2 , but we admit that with them the simple Mendelian ratio of 1:2:1 is never realized, though in large populations the parental sizes may reappear. Mendelians commonly try to account for the complicated ratios by assuming the presence of multiple factors; non-Mendelians point to the same ratios as quasi-evidence against Mendelian inheritance. I here offer a different explanation.

In the F_1 fruit $6 \times 6 \times 6$ the size character 6 is not the result of a factor for size 6, but of the three forces exerted by two size factors and

one modifier. It has not been assumed in the above explanation that the partners in an F_1 "factor" fuse to make a new factor. Thus we have to deal in both ♂ and ♀ gametes produced by the F_1 with factors 4 and 9 for each of the three size factors, length, breadth and thickness, occurring in equal numbers, and mating by chance (in self-fertilization). This is the same assumption made by Mendelians, even if they should not admit the F_1 inheritance of $x = \sqrt{ab}$. There would be these eight possible combinations uniting with each other by chance:

Combination	Length	Breadth	Thickness
1	4	4	4
2	4	4	9
3	4	9	4
4	9	4	4
5	9	9	4
6	9	4	9
7	4	9	9
8	9	9	9

These would result in the following 64 matings:

Mating	Resultant	Volume
1 × 1	4 × 4 × 4	64
1 × 2	4 × 4 × 6	96
1 × 3	4 × 6 × 4	96
1 × 4	6 × 4 × 4	96
1 × 5	6 × 6 × 4	144
1 × 6	6 × 4 × 6	144
1 × 7	4 × 6 × 6	144
1 × 8	6 × 6 × 6	216
2 × 1	4 × 4 × 6	96
2 × 2	4 × 4 × 9	144
2 × 3	4 × 6 × 6	144
2 × 4	6 × 4 × 6	144
2 × 5	6 × 6 × 6	216
2 × 6	6 × 4 × 9	216
2 × 7	4 × 6 × 9	216
2 × 8	6 × 6 × 9	324
3 × 1	4 × 6 × 4	96
3 × 2	4 × 6 × 6	144
3 × 3	4 × 9 × 4	144
3 × 4	6 × 6 × 4	144
3 × 5	6 × 9 × 4	216
3 × 6	6 × 6 × 6	216
3 × 7	4 × 9 × 6	216
3 × 8	6 × 9 × 6	324

Mating	Resultant	Volume
4 × 1	6 × 4 × 4	96
4 × 2	6 × 4 × 6	144
4 × 3	6 × 6 × 4	144
4 × 4	9 × 4 × 4	144
4 × 5	9 × 6 × 4	216
4 × 6	9 × 4 × 6	216
4 × 7	6 × 6 × 6	216
4 × 8	9 × 6 × 6	324
5 × 1	6 × 6 × 4	144
5 × 2	6 × 6 × 6	216
5 × 3	6 × 9 × 4	216
5 × 4	9 × 6 × 4	216
5 × 5	9 × 9 × 4	324
5 × 6	9 × 6 × 6	324
5 × 7	6 × 9 × 6	324
5 × 8	9 × 9 × 6	486
6 × 1	6 × 4 × 6	144
6 × 2	6 × 4 × 9	216
6 × 3	6 × 6 × 6	216
6 × 4	9 × 4 × 6	216
6 × 5	9 × 6 × 6	324
6 × 6	9 × 4 × 9	324
6 × 7	6 × 6 × 9	324
6 × 8	9 × 6 × 9	486
7 × 1	4 × 6 × 6	144
7 × 2	4 × 6 × 9	216
7 × 3	4 × 9 × 6	216
7 × 4	6 × 6 × 6	216
7 × 5	6 × 9 × 6	324
7 × 6	6 × 6 × 9	324
7 × 7	4 × 9 × 9	324
7 × 8	6 × 9 × 9	486
8 × 1	6 × 6 × 6	216
8 × 2	6 × 6 × 9	324
8 × 3	6 × 9 × 6	324
8 × 4	9 × 6 × 6	324
8 × 5	9 × 9 × 6	486
8 × 6	9 × 6 × 9	486
8 × 7	6 × 9 × 9	486
8 × 8	9 × 9 × 9	729

Among the possible combinations there are 16 in which both ♂ and ♀ have furnished the factor for length 4, and it has been commonly assumed that therefore one quarter of the F_2

population should show the character of length 4. The column of volumes, however, shows that there is only one out of the 64 with a volume 4³. All others with factors for length four have larger volumes, because their factors for breadth and thickness are greater than four. Here again the law of the golden mean is followed as all combinations bearing unequal size factors are forced to build cubes by the modifying factor shape. Evidently all matings resulting in equal volumes will make equal cubes and therefore show equal characters of length, breadth and thickness, though not necessarily possessing equal size factors nor even the factor for the size which they exhibit. If we group the results by volume and length of side, we have:

Volume	Instances	Side of Cube
64	1	$\sqrt[3]{64} = 4.$
96	6	$\sqrt[3]{96} = 4.57 -.$
144	15	$\sqrt[3]{144} = 5.25 +.$
216	20	$\sqrt[3]{216} = 6.$
324	15	$\sqrt[3]{324} = 6.87 +.$
486	6	$\sqrt[3]{486} = 7.86 -.$
729	1	$\sqrt[3]{729} = 9.$

That means that the chance for a parental size (whether line or surface or volume) to reappear is only 1:64 instead of 1:4. Moreover it is clear that each of the 8 possible combinations given on page 7, when mating with its like, will breed true to all three size characters, and continue to breed true thereafter if selfed. That means that these matings will form constant races, viz.:

Mating	Resultant	Volume	Size
1 × 1	4 × 4 × 4	64	4
2 × 2	4 × 4 × 9	144	5.25
3 × 3	4 × 9 × 4	144	5.25
4 × 4	9 × 4 × 4	144	5.25
5 × 5	9 × 9 × 4	324	6.87
6 × 6	9 × 4 × 9	324	6.87
7 × 7	4 × 9 × 9	324	6.87
8 × 8	9 × 9 × 9	729	9

Besides the parent-like strains then, we shall seemingly have two other races, one of volume 144, size 5.25, the other of volume 324, size 6.87, which will continue to breed true if

selfed. Each of these strains consists of three gametically different, though visibly indistinguishable lines, which when crossed will give an F_1 equal to both parents, but segregating to some extent in the F_2 . The finding in the F_2 or later generations of lines which breed true to size characters is thus not proof of the presence of multiple size factors in the original parents, etc.

In the bulletin in preparation I intend to discuss the bearing of the law of the golden mean upon the interpretation of inheritance of shape and number, mutants, latent factors, inhibitory factors, coupling and repulsion, factors other than those of size, shape, and number, and other points as they may come up, but for the sake of science I invite investigation into these relationships on the basis I here offer, even before I am able to publish the bulletin, which may not appear for several months.

B. H. A. GROTH

"THE LOWEST TEMPERATURE OBTAINABLE WITH ICE AND SALT"

FAHRENHEIT placed the 0° mark on his arbitrary thermometer scale at "the lowest temperature obtainable with ice and salt" or 32° below the freezing point of water, believing that water did not have a constant freezing point because of the undercooling which precedes solidification.¹

While discussing freezing mixtures with a friend recently I stated that a temperature of -19° C. could be easily obtained and maintained for some hours with an ice and salt mixture. My friend questioned the accuracy of the thermometer inasmuch as -19° C. is below 0° F. (0° F. = -17.78° C.). I have, therefore made a careful test to ascertain whether an ice and salt mixture may not show a lower temperature than 0° F.

About a gallon of finely chopped, hard, ice was mixed with a quart or more of coarse salt in a water-tight wooden box, the wooden box being used because of the insulation which it

¹ See Encyclopedia Britannica, 11 ed., "Heat," article 2.

afforded. The temperature was then observed with five thermometers:

Thermometers 1 and 2 were "nitrogen filled" thermometers graduated in Centigrade degrees ranging from -29° to $+360^{\circ}$ in 1° intervals. These are the ordinary high-grade laboratory thermometers.

Thermometer 3 was a small "Anchutz normal" thermometer reading from -25° to $+50^{\circ}$ in $1/5^{\circ}$ intervals. This is one of the most accurate types of chemical thermometers obtainable.

Thermometer 4 was a large thermometer of the same type as No. 3, but reading from -19° to $+360^{\circ}$ in $1/5^{\circ}$ intervals.

Thermometer 5 was an ordinary Six's maximum and minimum thermometer graduated in degrees Fahrenheit, each graduation representing 2° .

Thermometer 6 was a standard Weather Bureau type minimum thermometer reading from -35° to $+115^{\circ}$ F. in 1° ranges. This is probably one of the most accurate types of Fahrenheit thermometers obtainable.

Thermometer No. 6 was spirit filled. No. 5 contained a combination of spirit and mercury and all of the others were mercury filled.

Thermometers 1, 2 and 3 gave the same temperature for the ice and salt mixture, *i. e.*, -21° C. which is the equivalent of 5.8° below zero Fahrenheit. Thermometer 4 was graduated only to -19° C. and the mercury was some distance below the bottom of the scale. By interpolation a reading of -20° to -21° C. was made. Thermometer 5 gave a minimum of -4° F. while the Weather Bureau thermometer (No. 6) gave a reading of -5° F.

Previous to this experiment I had filled a wooden box holding perhaps 30 pounds of ice with a freezing mixture in the evening and placed it in an empty ice box to conserve ice. In the morning I noted a temperature of -19° C. (-2.2° F.).

From these experiments I am convinced that 0° F. is not "the lowest temperature obtainable with ice and salt." Just what the "lowest temperature" is I am unable to state, having failed to secure a greater lowering than -21° C. Theoretically the lowest tem-

perature should be the cryohydric point (-22° to -23° C.) where the cryohydrate, ice and salt containing 23.6 per cent. of NaCl, separates.

ROSS AIKEN GORTNER

THE AMERICAN PETROLEUM SOCIETY

THE American Petroleum Society was organized September 10 at the U. S. Bureau of Mines, Pittsburgh, Pa. This organization is the result of an effort of the bureau for the past seven years to bring together the men interested in the petroleum industry.

Invitations were sent out in July to the secretaries of twenty-four of the great national societies of the United States, inviting them to be present and to cooperate in this organization. Eighteen of these societies responded at a meeting on August 1 at the Bureau of Mines. A similar invitation was sent out in August to eight additional societies, making a total of thirty-two societies that were invited to attend the September conference. A large number of these were represented at the meeting on September 10, when the final organization was completed.

This society will concern itself with the study of all phases of natural gases and petroleums, including the origin, statistics, conservation, drilling methods, production, transportation, storage, refining and specifications for refined products.

When it is considered that each year, within the United States alone, there are produced crude petroleums and natural gases having a value in excess of \$200,000,000, and that no society has ever been organized in America for their comprehensive study it is reasonable to suppose that the future of this society is assured. There is to-day a tremendous waste of natural gases which, by proper methods of drilling, could be prevented. Also, there is waste of crude oil due to improper methods of production and handling. The necessity for a critical study of petroleums and gases by the members of such a society is evident.

At the meeting on September 10 at the Bureau of Mines the constitution and by-laws were adopted, and officers were elected as follows:

President, C. D. Chamberlin, National Petroleum Association, Cleveland, Ohio; *Vice-president*, R. Galbreath, Independent Oil and Gas Producers' Association of Oklahoma, Tulsa, Okla.; *Secretary*, Irving C. Allen, U. S. Bureau of Mines, Pittsburgh, Pa.; *Treasurer*, Warren C. Platt, Independent Petroleum Marketers' Association of the United States, Cleveland, Ohio; *Acting Past President*, Frank B. Fretter, Western Petroleum Refiners' Association, Coffeyville, Kansas. In addition to the foregoing these members were also elected to serve on the executive committee: Ralph Arnold, Geological Society of America, Los Angeles, Cal.; C. F. Clarkson, Society of Automobile Engineers, New York City; G. M. Swindell, Chamber of Mines and Oil, Los Angeles, Cal.; Edmund O'Neill, American Chemical Society, University of California, Berkeley, Cal.; E. B. Rich, Gasoline Producers' Association, Parkersburg, W. Va.; George H. Taber, American Society for Testing Materials, Pittsburgh, Pa.

The first annual meeting will be held at New Orleans, La., October 16 and 17, 1914, and the second annual meeting will be held at the Panama-Pacific International Exposition in San Francisco, October 25 to 30, 1915. At the 1915 meeting it is anticipated that all of the petroleum societies in the country will meet in one great congress where many things of interest and of value will be presented.

An official invitation has been sent from the president of the Exposition at San Francisco to the president of the International Petroleum Commission, Karlsruhe, Germany, to hold the 1915 meeting of the International Petroleum Commission in San Francisco. This meeting will be part of the great meeting of the petroleum industries where the foremost petroleum technologists and scientists of the world will congregate. Plans are already being formulated for this great 1915 meeting.

IRVING C. ALLEN

BUREAU OF MINES

THE AMERICAN BISON SOCIETY

At the annual meeting of the American Bison Society, held in New York on January 8, 1914,

important action was taken relative to extending the work of the society by the passage of the following resolution, proposed by Professor Henry Fairfield Osborn and seconded by Dr. Wm. T. Hornaday:

Resolved, That the protection and propagation of the prong horn antelope be immediately undertaken by the American Bison Society in connection with its work for the buffalo, and that the board of managers be asked to request the president and officers to formulate and execute a plan whereby this purpose may be carried out.

At the annual meeting of the board of managers, after a brief discussion of this matter, the president and executive committee were instructed to take such action as they might deem best as soon as possible.

President Hooper, in his annual report, gave an interesting summary of the work already accomplished by the society, and pointed out several directions in which effort should be directed during the coming year. He called attention to the fact that when the society was organized some eight years ago only 1,100 pure-blooded bison were known to exist in North America, while on January 1, 1913, 3,453 animals were listed in the census compiled by the society, an increase of over 300 per cent. During the past year the Wind Cave National Game Preserve has been established at the instance of this society, and has been stocked with fourteen bison presented by the New York Zoological Society from its herd in the Bronx Park.

The work awaiting the society during the coming year was listed by President Hooper under three heads: (1) The establishment of a herd in Sully's Hill National Park, North Dakota, (2) the establishment of a state herd in New York state or elsewhere, (3) encouragement of the preservation of the prong horn antelope, and possibly of other species of big game animals.

Dr. T. S. Palmer, of the U. S. Biological Survey, called attention to the possibility of establishing a state herd in West Virginia on the preserve of the Allegheny Sportsmen's Association. He also stated that the Montana, Wind Cave, Niobrara and Wichita ranges were all well suited to antelope.

It was felt that the society could well take pride in its recent achievements, but that its efforts must not in any way be relaxed during the coming year.

Ventilation and Humidity in Textile Mills and Factories

By CECIL H. LANDER, M.Sc., A.M.Inst.C.E., Lecturer in Civil Engineering in the University of Manchester. Crown 8vo. \$1.40 net (weight, 16 oz.).

The object of this work is to present an account of the general questions of ventilation and humidification in Textile Mills and Factories considered mainly from the point of view of abating the high temperature to which, notwithstanding the efforts of Owners and Managers, these rooms sometimes attain during hot weather.

A short account of the various Factory Acts and a general discussion of the subject is given in Chapter I. The principal methods of humidification together with descriptions of various systems in common use, comprise the second Chapter. The remainder of the book is devoted to a consideration of the means by which the maximum temperatures in the rooms may be reduced either by modifications in construction, in humidification, or in methods of working.

The Theory of Heat Engines

By WILLIAM INCHLEY, B.Sc., A.M.I.Mech.E., Lecturer in Engineering in the University College, Nottingham. With 246 Diagrams and numerous examples; Steam and Mathematical Tables and Index. 8vo. \$2.25 net (weight, 36 oz.).

Third Edition, Rewritten

Whipple—

The Microscopy of Drinking Water

By GEORGE C. WHIPPLE, Gordon McKay Professor of Sanitary Engineering, Harvard University.

xxi+409 pages, 6 by 9, 73 figures and 6 plates in the text and 19 full-page plates in colors. Cloth, \$4.00 net.

This book serves as a guide to the water analysis and the water-works engineer, describing the methods of microscopical examination, assisting in the identification of the common microscopic organisms found in drinking water and interpreting the results in the light of environmental studies.

It is also the purpose of this book to stimulate a greater interest in the study of microscopic aquatic life and general limnology from the practical and economic standpoint.

NEW MICROSCOPE FFS 8

MICROSCOPE FFS 8

Equipped with Abbe Condenser; 2 Iris diaphragms; 2 eyepieces; 3 objectives, 16 mm. (2/3-in.) and 4 mm. (1/6-in.) dry and 1.9 mm. (1/12-in.) oil immersion.

Price, \$67.50

A NEW microscope with *side fine adjustment of the lever type*. The principle is that of our original lever type of fine adjustment which has met the test of time and has been very generally adopted. The construction is simple and durable, giving a delicate movement for work with the highest powers, yet rapid enough for the lower powers.

The stand is of the same form as our FF and embodies all the good features which have commended that model to so many purchasers.

WHAT is scholarship? The answer is: The discovering, the organizing and the explaining of new facts. Only the uninformed and unscholarly are in the habit of designating the mere diffusion of knowledge as scholarship. The man who merely reads and speaks what he reads is no scholar, nor is the man a scholar who merely requires others to study what is already known. Any nation that believes only in the diffusion of knowledge is on the road to decay. But it is not my purpose to prove the generally accepted notion that productive scholarship is the only scholarship. We must, however, agree on the value of scholarship or the argument in this paper can have no importance. That no one may say that our subject is idle talk, I want to say, I believe for any nation that has any hope of perpetual existence that the scholars are the most essential of any class of society. And may we postulate, for the sake of the argument, that God will not provide and take care of the scholars?

And what is the predicament of scholarship in America? Simply this: That the institutions that have attempted to foster scholarship have not lived up to their opportunities. We may inquire into the reasons later. The one solution that the author proposes is to establish a new and higher institution, whose sole purpose would be to promote scholarship, and thereby furnish a new inspiration to educational, industrial and private establishments.

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

¹ Read before the Outlook Club of the University of Iowa at the February meeting.

I shall confine my arguments to the one field of scholarship with which I am most familiar, and trust that my readers who are most familiar with other fields will notice the close parallelism to the predicament in physics. And perhaps to those also a solution similar to the one here proposed will seem advisable.

To avoid any tone of pessimism, the views of the author will be presented in a constructive way, with the subject-matter, a plea for the physical institute in America; this institute to serve scholarship in physics much as the physical institutes of the German universities, the Royal Institution of England or the Cavendish Laboratory at Cambridge serve scholarship.

America has not led in thought since the days of Franklin. America follows thought. Consider some of the recent achievements in physical science; X-rays and their nature, Hertzian waves, liquid air, liquid helium, cathode rays, positive rays, radium and radioactive bodies, alpha rays, beta rays, the construction of matter, the photo-electrons, the theories of radiation and of fluorescence, the relations of heat conductivity to electrical conductivity. These and practically every recently proposed fundamental principle and important discovery in modern physics has come from abroad. But it is not necessary to make any apologies in behalf of Yankee ingenuity. I am speaking only in behalf of basic knowledge.

A PLEA FOR THE PHYSICAL INSTITUTE IN AMERICA

In making a plea for the physical institute in America I am making a plea for greater efficiency in the development of pure science in this country. It is believed that the time is overripe for the segregation of a small group of the ablest scholars in experimental and theoretical

physics, who shall have all the inspiration of close association with scholars in like work, all the facilities that an immensely wealthy country can provide, and who shall be free from the routine work of clerical management or the routine of teaching of disinterested or incapable students. The argument is simple and it is believed irrefutable, and is presented without in the least minimizing the value of a scattered scholarship for the general inspiration of a student body and the general public.

The time is believed to be overripe because we are spending more money on higher education per capita than any country of the globe, and at the same time it would be bold to claim a second-rate place for ourselves in the development of pure physical science. The situation generally in our universities is such as to discourage the development of capable and promising young men by management that encourages faithfulness to second-rate ideals. We are already on the verge of an over-production of zealous and promising scholars, who can see no future other than that of servitude in the small college or with detail or clerical work in a laboratory swarming with students. Admit if you will that it is all good work and also that the soul must do penance, nevertheless the bright and capable young man, even if he has a vision, insists on looking ahead to a life of respectability and achievement with an ultimate freedom from the worries of the things of life.

Our commercial enterprises are just discovering that much of this ability can be easily and most profitably adapted to the advancement of applied science. And it must be said to their credit that they already bid fair to surpass most of our universities in pure science, even though their ideal is admittedly to make scholarship pay in the near immediate future. The

wonderful success of some of our commercial research laboratories should furnish a genuine stimulus to those of us who believe in greater opportunities for pure science. Of course if we should not believe in a scholarship in science which is not hampered by questions of immediate rewards, then there is no occasion for the plea in this paper. A discussion of the organization and the scope of a working institute can best be given after we have first analyzed somewhat in detail the existing conditions which are manifestly not as efficient as they should be. And lastly, we should be in a position to outline a tentative plan for the development of the organization.

THE SITUATION IN OUR UNIVERSITIES

The idea of the physical institute is to supplement the work of our universities by founding a higher standard and furnishing a new source of inspiration. True enough, our universities have sufficient resources to properly foster the work of a physical institute, and there is an abundant supply of men forthcoming. Moreover, they believe in general that productive scholarship is the most important function of a university and it is agreed that genuine scholars are of the most rare and difficult type to develop. But the difficulty with our universities is one that arises from mixed ideals, particularly in our state universities. The ideal of competition perhaps takes precedence of all other ideals in practise, and along with this is associated the ideal of efficiency in detail management of students. Surely a university wants scholars, but it wants a large number of students first. It wants more students in order to convince the people of its greatness, so that it may get more money so that it may establish more departments, and so get more students, and so on. It

must do extension work so that the work of scholars may reach every citizen of the land within a few days after it has been accomplished. Energy and resources that might be directed toward scholarship are scattered in every direction that human imagination can conceive of. The ideal in practise is not how great scholarship, but how thin can it be spread. In other words, there is in our scholarship a strong tendency toward democracy gone mad. Now if only one side of the situation in our universities is emphasized, may it be remembered that the author wishes to make clear a difficulty which can be side-stepped in one particular by the organization of the physical institute. Of course the administrative authorities of most universities would remind us that they are building for the future. Their ideal is service in a broad sense. Scholarship first in so far as it is first in service to the immediate mass of humanity. Scholarship for the sake of scholarship—never! But if we will admit the result of the recent investigations of Professor Cattell, which is that our administrative officers generally can have no vision of the value of scholarship to the future of society, we can proceed with our argument. The argument of the administration against scholarship is much like that of one farmer toward the education of his son. No, no, my son, you must stay out of school a few years and safeguard the future. We will raise more corn and feed more hogs, so that we can buy more land, and raise more corn, etc., and by and by you can go entirely through the university and take your brothers and sisters along if you yet have the desire.

The predicament of the state universities is well stated by Professor Geo. J. Peirce:

The masses of a democracy recognize present wants more surely than they anticipate future

needs. They require an immediate supply to meet an existing demand. They consider a state university to be well fulfilling its function if it furnishes such a supply. . . . But the wholesale business of the state university limits if it does not prohibit that attention to the exceptional student which may result in training a leader of his generation, a seer who, divining the future needs of the state, may begin to prepare to meet them, a man who, profiting by the recorded experience of the past, may mold as well as meet conditions.

And what has been the result of the material growth of our universities on the development of physical science in this country? We have laboratories of marble and cases filled with apparatus, and hordes of students, and a wonderful machine-like system to care for these students. But the efforts and resources adapted to scholarly purposes are not at all in proportion to merit. Even now we are confronted with a difficulty which shows us the need and opportunity of concentrating our efforts toward scholarship. Every year we have young men of good promise who either can not find positions at all in our universities, or who are compelled to take positions with such requirements and surroundings that the development of the individual is practically impossible, and at the same time every year the universities can not find enough mediocre men at salaries ranging from \$600 to \$1,000. The demand is for men who will take care of these hordes of students, men who will lead these students by the hand and feed them with a spoon, men who will set up elementary experiments, grade notebooks and daily examination papers, and correct English, and who thereby make parents and patrons believe that everything is moving along smoothly and efficiently. For if the students do not appear to be busy the institution will get a bad name and the number of students will not increase. And what can be worse than an idle student body or a lack of increase of students. It is no doubt true that in

some instances scholarship is not developed in physics because the members of the department staff are beyond hope of becoming scholars and they either have no knowledge of what tends to develop scholarship or are afraid that some individual might develop who would be a greater man than those on the ground floor. But this latter is pure hypothesis.

What is needed is a higher light on American soil. Too many professors are satisfied to spend their time making out and mimeographing notes and examinations, and even making apparatus, or in conferences with the laggard students, or perhaps with unimportant committees. Sometimes they do not realize how poorly they invest their time when they are merely reading and becoming informed, as it were. Frequently professors keep themselves so busy with labors like the above and even such cheap labor as dusting apparatus that they do not have time and energy left for the merest semblance of thought. Productive scholarship is the flower of our educational work and that individual who shows tendencies to bloom should be allowed the every ounce of his energy to apply in this direction.

I believe it is not fair to blame the ruling bodies of our institutions too much, for they are merely the creations of a complex set of circumstances in our overemphasized democracy. Men with ideals when in power find themselves faced by situations which seem to require a single line of procedure in order to preserve any semblance of power. The reader will please not understand that our universities are devoid of good administrators, or that scholars are unknown. Moreover, there are evidences of forces at work for the improvement of our administrative methods in the universities, and there are urgent appeals for the improvement of scholarship. But I be-

lieve that the progress can be made more rapid, and that scholarship in theoretical and experimental physics can be more quickly put where it should be by the development of a new and higher institution, which shall be largely unhampered by the accustomed administration and students of our universities.

And I can not proceed further without saying a familiar word about our students. The students in our universities may be divided into three classes, as follows: those who early in their university career think they know how they wish to function in society and who remain in the university primarily as an aid to carrying out serious purposes—those who attend the university for a pleasant life and ultimate social standing primarily, who, like Micawber, trust that something will turn up—and those with a serious desire to specialize in some line of human activity after they have obtained some notion of the relative merits of the various classes of activities and their own fitness and interest.

Those of the first class constitute a large portion of the students of our professional colleges. The average brightness and capability of this class is very good. Perhaps this is because of the definiteness of procedure, and the assurance of a life of comfort and respectability. Perhaps some are afraid of being classed with the non-serious, purposeless ones and again some do not trust themselves to a broad career with its many chances and pitfalls.

The second class are the most numerous generally. They sometimes study elementary physics, and they usually get some good as a result of their sojourn in the university. No doubt the average of society is raised. Some who come to scoff remain to pray. The only objection to this class of students is that they are not worth their cost. Of course they can not be eliminated because of the difficulty of discerning who

belongs to this class and because of the political dangers. The students of the third class are all too few in number, and of this class the contamination by the other classes is so great that the net weight is frequently vanishingly small. From this third class we should draw our scholars in all fields of pure science and the humanities, our artists, our administrators in many fields, including senators, representatives, college presidents and leaders, wherever there is a fight between the old and the new, because forsooth these men should view human activities in the broad sense, and therefore should recognize what efforts conform to the development of society and the universe.

Now the great criticism that a physicist in particular may bring against our universities is that the cream of the time and energy of the university professor is taken in contact with students of classes one and two.

THE SITUATION IN OUR INDUSTRIES

And what is the situation in our industries that we should declare that it is impossible for industrial research laboratories to properly develop science, no matter how much wealth and energy they may expend for investigation. In order to answer this question we may inquire into their ideals and methods, their resources and their achievements.

The ideal in our industries is admittedly investigation that pays, *i. e.*, investigation for a useful purpose. Now, as Dr. Whitney points out, the pay comes in two directions—one in returning more dollars and cents than is invested in the research laboratory, and, secondly, in maintaining the practise of the manufacturing concern by being ready to cope intelligently with any other concern that may attempt supremacy as a result of new discoveries. It may be unfair to pronounce upon the question as to whether there is a soul in a commercial enterprise that leads it to desire to achieve

for no other reason than to keep its name and its work preeminently on the map throughout the ages. Perhaps this latter phase of the ideal may exist even though its workers may be largely unaware of it. At any rate, I believe it is generally admitted that it is desired that material rewards shall be forthcoming in the near future. If it could be that wise leaders in industrial research could recognize the value of pure science to the industries centuries hence, then there would be not so urgent a plea for the physical institute. But these concerns are of human hands and in a democratic country, and the resources generally come from individuals who expect dividends at least in due time to be incorporated in the death wills of the stockholders. I believe that as a corporation grows large it tends toward the recognition of values other than immediate money values. If so this is cause for larger faith in humanity. In fairness we must also recognize the struggle for corporate existence the same as we recognize the struggle of the individual. It is, for example, perhaps difficult to know to whom should be given credit for the establishment of such able and broad-minded leadership as prevails at the General Electric Company's laboratories.

The pure scientist believes that it is most difficult to obtain willing and capable men who will devote all their energies to the search for new knowledge by the free and methodical movement of the human mind, without regard to practical applications and money rewards. He believes further that this is the only royal road to intellectual achievement, and yet he is not unmindful that some time or other much of the knowledge will be absolutely necessary to the existence of the human race. He believes that the man who investigates with a commercial purpose in view has a handicap load that must limit him in his arduous search to the extent that such an

investigator can only be half a scientist.

The attitude of the commercial scientist may be gathered from the words in part of Dr. Arthur D. Little in his recent presidential address before the American Chemical Society:

Most of us believe that the doctrine science for science's sake is as meaningless and mischievous as that of art for art's sake or literature for literature's sake. These things were made for man, not for themselves, nor was man made for them.

The pure scientist is perfectly aware of the immediate value to humanity of this attitude, but at the same time he insists that there should also exist a body of most capable thinkers who shall not be limited by placing dollar signs ahead to mark out the paths. Even from the standpoint of service the dollar mark often leads away from the best route or the safe route. For what man of Faraday's time could have predicted that within a century the electrical industries of one country would be facing a capital requirement of \$8,000,000 a week.

That research pays our industries acknowledge fully. They are aware that in farming alone investigation has resulted in the saving of about \$1,000,000 in the labor cost of a single crop and a very much larger saving as a result of increased yield, as compared with fifty years ago, or that in electric lighting alone fully the same sum has been saved annually as a result of the progress in the last ten years. And I doubt if it could be estimated the returns that have come to the steel industry or the telephone industry as a result of their years of special researches. According to Dr. Little there are several industrial firms that are now spending \$300,000 annually on their research laboratories, and many more, \$100,000 a year. These figures should certainly make those interested in the promotion of pure science take notice. It is perfectly obvious that it is a concentration of effort and resources of our much-talked-of trusts that has made possible these wonderful expendi-

tures and the advances which have followed. As a result of cooperation of several firms we have the National Electric Lamp Association Physical Laboratory at Cleveland, which perhaps approaches more nearly to a pure-science laboratory than any that are fostered by the industries. But this laboratory can not divorce itself from the interests that nourish it. Its investigators will naturally have regard for problems which seem to bear on the industry.

Also there is the Bureau of Standards, whose good work is so well known. This bureau spends annually about \$700,000. But the spirit of this institution is toward the refinement and the standardization of the best that has been or about to be accepted in the scientific world. The scientists of this bureau are in a sense the conservers of scholarship. It is only occasionally that they expend energy toward the development of pure physics. They find plenty to do in the field they have chosen. It is very doubtful if this organization with its congressional control and red tape would be conducive to the free and easy movement of the human mind in scholarly productions.

In this connection the opinion of General A. W. Greely is worthy of note, which is:

The failure of our government to properly recognize scientific work appears to be due to an antiquated and inherited policy, which must be to the ultimate detriment of the common weal. This year the attention of the government has been urgently called to the untoward conditions, arising from illiberal treatment of expert officials. Distinguished chiefs of several important national bureaus officially report increasing difficulty in maintaining an efficient scientific staff. Unusual and steadily increasing numbers of scientists and experts are accepting commercial positions in order to meet the enhanced cost of living.

THE ORGANIZATION OF THE PHYSICAL INSTITUTE

The organization of the physical institute

should be such that a few of the greatest world physicists could be induced to join it and remain with it. The things that such a man needs are freedom from cares concerning food and shelter, livable surroundings, human associates who are interested in like work, and freedom from petty administrations, and perhaps the last two would be most effective in retaining men and keeping them effectively at work. Our universities and government bureaus frequently furnish the first two requisites, but seldom the last two. If any furnish all four, I shall let those who know say it.

The first condition would perhaps be filled satisfactorily if the physicists could have a salary of \$10,000 each. The surroundings should be a laboratory fully equipped, situated preferably in some quiet spot and beautiful and within easy reach of some metropolis. Nearness to some large university would also be helpful.

The associations would be partly supplied by the other men of precisely equal standing at the laboratory, but this would not suffice for the men or the cause. There should be a number of fellows of standing about equal to that of our best new doctors of philosophy. They should obtain stipends of about \$1,500, and should be allowed to keep these appointments for as many years as they see fit, of course devoting their time to research, with all the aid that they can obtain from the honored physicists, or honored professors, if you prefer. Also there should be as many students in theoretical and experimental work as the honored professors might wish to accept.

The administration should be entirely in the hands of these professors, who may elect a qualified secretary to take care of the routine business management. Any new appointments to the professorships or fellowships should be made only in case of

deaths or voluntary removals. No alteration should be made in the salaries or the essentials of the organization except by unanimous vote of the administration. The institution should be conservative, so that there might be no occasion for troubles and so that there might be ample time to test the ideal of the laboratory.

The institution should have the power to confer a special honorary degree on any man of the institute or elsewhere for pre-eminently noteworthy work in physics. This degree should bear no relation to the period of service of the candidate. This would aid in giving the institute a rightful leadership in scholarship.

An American institute for physics with the ideal for scholarship alone, should be fostered by private endowment, by a governmental bureau or by a national university, but hardly by any university such as exists already. A private endowment would be preferable from all points of view save perhaps one, providing of course that no strings were tied to the endowment inconsistent with the ideals of the institution. A privately endowed institution might not tie itself up with our nation and our existing educational institutions as fast as if it were otherwise fostered. And yet the success of the Rockefeller Institute for Medical Research would tend to dispel this notion. The capitalization need not be beyond a private endowment, for the income could be less than that spent by many industrial concerns on research, but of course more than spent by most universities for research.

A governmental bureau might foster such a project if it could only have a charter that would insure it a semi-permanent freedom from disturbances arising from the petty rules prevailing generally in our governmental bureaus. Such an action by our government would create a tremen-

dous sentiment in favor of scholarship throughout our democracy. It is not unreasonable to expect that national support of scholarship would create a national spirit somewhat like that in Germany, for it is well known that the government there has long fostered scholarship and that German industrial supremacy has come as a result of supremacy in productive scholarship. According to Professor Mann, Germany has established a separate lot of schools to take care of the technical education which our state universities feel called upon to provide for.

The government might cooperate in a physical institute somewhat on the basis of the work done by the Carnegie Institution. Already this institution serves purposes closely akin to those of the proposed physical institute, particularly in geo-physics and in terrestrial magnetism, and yet there are obvious distinctions.

A national university might foster a physical institute properly, but there are grave doubts. It is not clear how such a university could be founded on federal support without the injurious meddling of the demagogue, who can not recognize any good to society that is not certain to extend to the masses in the present or near future generations. The attitude of Willet M. Hays, for example, who holds that a national university should reach ninety per cent. of the people in the present generation, may be all right for a technical school or high school, but this attitude should be regarded as positively vicious when applied to a national university. As the Assistant Secretary of Agriculture points out, already applied science is developing much faster than pure science. My opinion is that this only emphasizes our great need for institutions that shall develop leaders and prophets. Such an institution could, if properly chartered, in-

corporate a worthy physical institute. And this institute could pilot the way in those things that pertain to the development of physical science. A reasonable number of promising students would furnish working material for the honored professors, and later they would spread the gospel.

The publication of the work of such an institute would be a matter of detail and one that would take care of itself. I believe that a suddenly created national university with the proper ideals is an almost Herculean task. However, if several institutes of the character of the proposed physical institute could be founded one by one, these could later form a loose union for co-operation without waste of energy or loss of spirit.

If my readers are inclined to admit the strength of the argument in this paper when it is considered in connection with the efforts of our state universities, but not when considered in connection with our endowed universities, they should be reminded that the latter type of institution has not succeeded in retaining such physicists as Rutherford, Jeans, Richardson and Maclaurin. Other foreign physicists have even declined to try our atmosphere. Our self-respect demands that we attempt to create one center of physical research to which eminent world physicists would be willing and happy to come. I believe that with the establishment of the physical institute we should soon have the spirit, intelligence, work and courage of the American university professor in physics raised to such an extent that men would be honored with salaries as well as with ranking titles, such that the fellowship of students would mean inspiration rather than a deadly burden, such that irregular administrative management would not be tolerated, and such that

a correct public sense of values would be established.

F. C. BROWN

THE STATE UNIVERSITY OF IOWA

THE NEW MECHANICS

IN the past decade, rumors have become current that physicists were attacking critically the ideas which have been accepted in mechanics since the time of Newton. Articles have appeared which assert that there are two mechanics, the Newtonian or classical, and the non-Newtonian or modern. And it must occur to many to ask whether this is to be a war of words, as has so often resulted from looking at the same thing from opposite sides, or whether we are living in a world perplexed by two rulers, for we have pretty generally submitted to the doctrine that we and the rest of the universe are parts of a mechanical machine. And it would be an additional perturbation, in these already troublous times, to have to decide which governor to live under. While the laws of mechanics will probably be modified, still we are now certain that the changes will not affect problems involving matter in any of its ordinary aspects. The human race, in its present state of existence, will thus continue to conform to the laws of Newtonian mechanics; but we must be prepared for an early proclamation from Sir Oliver Lodge, the apostle of the science of spiritual mechanics, that death is merely the transfer of those complexes of the ether, called man, to a massive empty space governed by the laws of non-Newtonian mechanics—where our spirits move hither and thither with the velocity of light, and think with an energy comparable to the explosion of an atom.

The real issues of this very important discussion of the laws of mechanics are now fairly determined, and when the Société Française de Physique made them the subject of a conference, no one could have been found better fitted to state the case than M. Paul Langevin, of the Collège de France. Now that his opinions have been published, it is comparatively easy to present the ideas

underlying the new mechanics as a survey of his article.¹

M. Langevin begins his discussion with the statement that the idea of mass has been the fundamental concept of mechanics since the time of Newton, and that it may be introduced in three different ways which correspond to three aspects of inertia. We may define mass as the coefficient of proportionality of force to change of velocity as derived from the formula, force equals mass times acceleration ($F=ma$); as capacity for impulse or quantity of motion, from the formula, momentum equals mass times velocity ($G=mv$); as capacity for kinetic energy, from the formula, kinetic energy equals one half mass times velocity squared ($w=\frac{1}{2}mv^2$).

Rational mechanics, to be consistent, requires that there must be perfect equality among these three definitions of mass, and that the mass of any portion of matter must remain absolutely invariable for all velocities and for all changes of the body, whether due to physical, chemical or mechanical agents.

By inertia we ordinarily mean the property which matter possesses of tending to preserve its state of rest or of uniform motion in a straight line; that is, matter resists any change of motion in such a way that an external action or force is necessary to change the quantity or the direction of a motion. Newton based mechanics on this constant proportion between force and change of motion, or acceleration; and he defined mass to be the constant of this proportion. He thus assumes that mass, determined in any other manner, will give a consistent result with his definition.

And since the time of Newton, every treatise on physics has begun with this assumption, that inertia is the fundamental property of matter, in the sense that it can not be expressed in simpler terms. Indeed, for more than two centuries, it has been held to be the essential doctrine of mechanics, that a physical phenomenon was satisfactorily explained only when it was reduced to a type of motion

governed by the laws of this rational mechanics, and particularly by the law of inertia.

But now, after a searching criticism of the postulates of mechanics, many physicists have come to the conclusion that inertia is not a fundamental property of substance, and they claim to have proved that it can be reduced to simpler terms by the laws of electromagnetism, which show evidence of being simpler and more fundamental than the laws of dynamics.

First, because it can be proved that inertia is not invariable, since the quantity of mass, as measured by the three definitions given above, ceases to be the same when the velocity of matter is not small compared to the velocity of light.

Furthermore, although for small velocities the three definitions of mass agree and assign to a given portion of matter a definite initial or "stationary" mass, m_0 , yet even this initial mass depends on the physical and chemical state of the system and also varies for each change of state which is accompanied by an interchange of energy with an outside body.

This evidently means that, if a body radiates heat, light or electro-magnetic waves to other bodies, or if a body unites with another to form a new chemical compound, then the mass of the body in each case changes. The relation between this change of mass and the change of energy is found to be a very simple one, as the change of mass equals the change of energy divided by the velocity of light squared, or

$$m - m' = \frac{E^2}{w - w'}.$$

It follows because of the law of the conservation of energy that in a system of bodies whose separate parts mutually exchange energy, the masses of the separate parts vary, but the total mass of all the parts added together remains constant, if the system as a whole does not change its total quantity of energy. Thus the law of conservation of mass is merged into the more fundamental law of conservation of energy.

The inadequacy of mechanics became apparent when physicists attempted, without success, to explain electro-magnetic and optical phenomena from the accepted mechanical laws. We now see, as Professor Einstein has shown

¹ P. Langevin, "L'inertie de l'énergie et ses conséquences," *Le Journal de Physique*, July, 1913.

by the principle of relativity, that an essential error was introduced when the formulæ of dynamics and those of electromagnetism were assumed to lead to the same conceptions of space and time. According to the new mechanics, our ideas of time and space, obtained from mechanical notions, are only approximately true, while those derived from the laws of electromagnetism are correct. The result is many physicists of the new school are now seeking for an interpretation of inertia from the laws of electromagnetism rather than to continue to explain the laws of electromagnetism by mechanics. These laws of electromagnetism have the advantage of great simplicity of form which may qualify them to serve as the fundamental principle of all physical laws.

The germ of these new views of electromagnetism is to be found in the work of Faraday and Maxwell. Their true experimental foundation is Rowland's experiment, performed in 1878, when he found that an electric charge, if it be carried through space with a high velocity, acts like an electric current in that it creates about itself a magnetic field. Three years later, J. J. Thomson showed that, if an electrified body moves through space, it not only creates a magnetic field in the surrounding space, but also that this magnetic field is a form of mechanical energy; from the law of the conservation of energy, this energy must be acquired at the expense of an equal amount of energy localized in the free space about the body. Now it can be shown rigorously that this "magnetic" energy has all the characteristics of a kinetic energy, since it is proportional to the square of a velocity and contains a factor which corresponds with the mass as given in the third of our former definitions. This supplementary inertia of electromagnetic origin results solely from the fact that the body is electrified, and it is an addition to the stationary or initial mass which was denoted by m_0 .

The result is the same if we consider the second definition of mass, as a capacity for impulse or momentum. So soon as a body is electrified and moves, it develops a supplementary capacity for momentum which agrees

with the supplementary capacity for energy which has just been described. Poincaré, in order to preserve the fundamental law of the conservation of momentum, has shown that it is necessary to localize a quantity of momentum in space just as we were forced to localize a quantity of energy in space. Thus the fundamental consequence of rational mechanics, requiring the three definitions of mass to agree, is not satisfied for all cases of motion.

These ideas have affected our notions of space. Maxwell deduced as a consequence of theory that rapid and periodic variations in the electrical charge of a body should be propagated through space with the velocity of light. The existence of these electromagnetic radiations was verified experimentally by Hertz, and in the hands of his successors this new form of radiation has attained great importance under the name of wireless telegraphy. A theoretical consequence of this radiation is the now generally accepted belief that light is merely a type of electromagnetic radiation of excessively rapid vibration. To transfer the phenomena of light from a mechanical to an electromagnetic manifestation of energy was to shake profoundly the belief in the fundamental and universal nature of mechanical energy.

Another very important principle of rational mechanics was embodied in Newton's third law of motion, that to every action there is an equal and oppositely directed reaction. But we have not been able to make the forces created by an electrified body in motion conform to this law. This is especially evident when radiation also occurs. Let us suppose that an incandescent body is giving off light (*i. e.*, electromagnetic radiation) uniformly in all directions. By reason of symmetry this radiation exerts no resultant force on the source. But if the perturbation, in the form of a wave, encounters an obstacle at a distance, then we know, both from theory and from experiment, that the obstacle will be subjected to a force due to its absorbing a part of the radiant energy. This pressure of light pushes the obstacle in the direction of the propagation of the light, and the action thus exerted on the

distant body is not compensated by a reaction appearing at the source or on any other portion of matter. We thus have cases of actions without reactions, if matter alone is considered.

It must be clearly understood that the discrepancies involved in the results of the rational mechanics, which have been cited, do not become appreciable except under unusual conditions. We can still consider mass as an absolute constant and the equations of dynamics as exact, unless matter has a velocity exceeding 18,000 miles a second, or for changes of state which involve enormous quantities of energy, such as those associated with radioactive bodies or those which accompany the formation of the chemical atom. At the present day we have made no progress in attaining any of these conditions, for even in the case of radio-active bodies we should need to find a method of liberating their energy in hours rather than in hundreds of years. Thus the problem would have remained academic, if theorists had not advanced the hypothesis that electricity is atomic in nature and that the electron, as the least portion of electricity is called, ordinarily attains a velocity which does exceed a velocity of 18,000 miles a second; that radiation must be explained as a transfer of an entity, energy, through space; and that the chemical atom of the radio-active elements decomposes spontaneously and of all other elements is theoretically decomposable with the evolution of an enormous amount of energy. All of these theoretical cases would make the discrepancies between the laws of mechanics significant.

It would exceed the limits and the purpose of this article to attempt to follow M. Langevin in his exposition of the properties of electricity and of matter, of inertia, of radiant energy, and of the principle of relativity. After all, these abstruse questions are proper for the discussions of specialists as they deal with the nature of matter in a state quite outside the limits of observation. But however the hypotheses of electrons and the ether may impress the world as being matter of definition and words rather than of substance, yet

from them follow conclusions which can be tested experimentally. And the conclusions to be drawn from the new mechanics are interesting.

For example, from the assumption that the mass of a body varies when it gives out heat or light, we must conclude that if a pound of water at 32° Fahrenheit were heated to 212°, its inertia or mass would be greater. Unfortunately, when we calculate the increase of the mass for this or for any practicable heating of a body, we find that it is entirely too small to measure.

Again, let us put a known mass of hydrogen and oxygen in a closed vessel and cause them to unite to form water. Since the union of these gases liberates an immense amount of energy in the form of heat which will be radiated from the walls of the vessel, the mass of the water must be less than the combined masses of the two gases. But unfortunately again, the calculated decrease in mass is only a five-billionth part and thus entirely too small to measure.

Lastly, the radio-active bodies give off an amount of energy much greater in proportion to the mass acting than can be obtained by any chemical or other process. We might hope to measure the decrease of mass in these cases, but we can not, because these bodies give off their energy far too slowly.

Such, in the main, is M. Langevin's exposition of the new ideas in mechanics. There is not the least doubt that this rigorous searching of the classical mechanics has been a most important advance in science, and we are certain to find its laws must be revised in order to make them conform to the more rigorous exactness which is now required of mathematicians. But it is equally certain the laws of mechanics have withstood this criticism extraordinarily well, in so far as they have been unshaken when we are dealing with motions which can be attained by bodies of sensible mass.²

² That is, Newton's laws of dynamics are rigorous when bodies of tangible size, acting in measurable spaces and times, are investigated. They are approximations for exceptional cases; in much

The divergence of the new and the old mechanics occurs only for actions of separate electrons, of unattainable velocities, of energy existing in the chemical atom, and of radiant energy in empty space unassociated with matter. Now there are many men of science who think these problems are metaphysical, in that they do not deal with measurable bodies or with phenomena capable of experimental verification. And there is a great likelihood that problems of such a nature are incapable of scientific solution and are apt to drift into a discussion more of definitions and of words than of objective facts.

The warning which was given by Poincaré, shortly before he died, is one to be heeded by the over-zealous.

If, however, in some years, its rival (the new mechanics) triumphs, I shall venture to point out a pedagogic error that a number of teachers, in France at least, will not escape. These teachers will find nothing more important, in teaching elementary mechanics to their scholars, than to inform them that this mechanics has had its day, that a new mechanics where the notions of mass and of time have a wholly different value replaces it; they will look down upon this lapsed mechanics that the programs force them to teach and will make their scholars feel the contempt they have for it. Yet I believe that this disdained classic mechanics will be as necessary as now, and that whoever does not know it thoroughly can not understand the new mechanics.

LOUIS T. MORE

UNIVERSITY OF CINCINNATI,
December 3, 1913

GEORGE WESTINGHOUSE

My acquaintance with Mr. Westinghouse commenced in the spring of 1867 in Pittsburgh. He was at that time introducing to the railroads a patent car replacer and a double-headed railroad frog, both of his invention. These were being manufactured by Messrs. Anderson, Cook & Company, crucible steel manufacturers, I being employed by the same company. He was doing the selling—at the same time making his first acquaintance the same way as his more universal law of gravitation is accurate for ponderable bodies but fails for intangible molecular bodies.

with railroad men, so valuable to him in later years. We lived at the same hotel and later on, after we were both married for about a year, we lived in the same house on Penn Avenue, next door to where the great Westinghouse Building now stands, and, being of congenial tastes, our acquaintance ripened into a warm friendship which continued up to the time of his death.

During this time he often talked of the idea of operating the brakes of a railroad train by compressed air, one of the greatest advantages of which he thought would be the putting of the full control of all movements of the train into the hands of the engineer. He had witnessed a collision between two trains and saw the necessity of some better apparatus for controlling their speed than what was then in use. Not having the money to pay the expense of the first equipment, which only amounted to \$750, he gave a very substantial interest in the patent to one of the men who was afterward associated with him, in return for the necessary capital. This gentleman made over \$2,000,000 out of this interest in the Brake Company within the next twenty-five years.

He soon had all the details of the new invention worked out and the first train equipped. It was first tried on an accommodation train on the P. C. & St. L. Railroad, running west from Pittsburgh. It was a success from the very first, preventing a bad wreck and probably saving several lives within a week after its installation.

A company was soon formed and the manufacture of the brakes was commenced within a few months. He added from time to time improvement after improvement until in 1886 he brought out the automatic quick-action brake. The greatest rival of the air brake at that time was an electric brake. After studying this problem for some time, Mr. Westinghouse announced to his associates that he had conceived the idea of an improvement in the air brake that would make its operation quicker than the electric. No one could understand how this could be true, but when the brake was constructed and put in operation they found it was a fact.

The results of the working of this improvement proved that it was very much superior to the older form and that his claims were correct. The company then equipped a 50-car train with the improved apparatus. This was taken all over the continent from Boston to San Francisco, giving exhibitions at different points.

This settled the question beyond any doubt as to which was the best brake, and nothing more was heard of the electric brake, until the latest invention by Mr. Westinghouse within the last few months of the electric pneumatic, which is, as its name implies, a combination of the use of electricity and air pressure.

He early turned his attention to railroad signaling and was the father of the modern automatic signal, first using compressed air and later electricity and a combination of both.

The inventions of Mr. Westinghouse have done more for the safety of the railroad traveling public than those of all other inventors that have ever lived. People who travel will never know how much of a debt they owe for their safety to him. The fact is that to-day the safest place for a man to be is on a railroad train. This is proved conclusively by the fact that accident insurance companies pay double the face value of their policies if the death of the insured occurs on a public conveyance.

I think that the invention and development of the air brake was Mr. Westinghouse's greatest work. It certainly has done more in saving lives and making travel safe than all other inventions put together. The present generation can never know how much it means to them, but they will remember the name of Westinghouse more in connection with the air brake than anything else.

Mr. Westinghouse was quick to grasp the possibilities of any great invention or enterprise. This was shown in his development of the use of natural gas in Pittsburgh. The iron manufacturers of Allegheny County had been watching the use of this wonderful fuel by one mill for 15 years, all of them saying that it could be only temporary and would soon give out. After Mr. Westinghouse's

attention was called to it and he began studying the subject, he made up his mind that the supply of natural gas was immense and would last long enough to warrant the organization of a large company for its development and distribution. He, therefore, organized the Philadelphia company and in a few months had Allegheny County literally ablaze with the gas from many wells and was supplying the mills and private residences with the new fuel at a price which saved them millions of money besides paying handsome dividends to his stockholders.

To him more than any one else in this country is due the development and introduction of the alternating electric current. The story of its introduction in this country is well known, having been told by better pens than mine. The extent and magnitude of his electric and machine works far surpass any of his other enterprises. At the time it was built the floor space covered by the British Westinghouse Works at Manchester in England was as much as the combined Westinghouse electric works and the Westinghouse machine works in East Pittsburgh.

George Westinghouse had unlimited faith in himself and he had the courage of his convictions. He never asked his associates or the public to invest in anything in which he would not risk his own money. All of his stockholders could be dead sure of always having a square deal from him.

A frenzied financier once made a proposal to him which involved the sale of a company whose stock he controlled. The scheme as proposed by this man was that the stockholders were to get one price for their holdings while Mr. Westinghouse was to receive a much larger price for his. His reply was one of the most indignant, scathing and cutting letters that I have ever read and must have been anything but pleasant reading to the receiver.

It is given to very few men to be responsible for the creation of such great enterprises as those which were founded by Mr. Westinghouse, and he was justly very proud of them and of what they had done—but more than all else

for what they had done for humanity, especially in the introduction of the air brake.

We who knew him best were very proud of him and could not but love him, and for that reason we could have wished that he had devoted less of his time and energy to his enterprises in Europe and more to those on this side of the Atlantic. He would have had very much less worry and more peace of mind and comfort during the last few years.

He had a dream of seeing all of Great Britain's system of railways electrified. He thought the time had arrived when it could be done. This was his reason for the erection of the great works at Manchester, but he was a little ahead of the times. England is an ideal country for such a possibility, a network of railways, an immense number of short light trains, and coal mines so near that it would be quite within the range of developed possibilities of to-day to have the electric current generated by gas engines at the mines and distributed all over Great Britain by the high-tension electric system. None of the lines would have to be more than 200 miles long, most of them much less.

There are several schemes to erect monuments to the memory of Mr. Westinghouse. There can not be too many, or too costly; but after all the greatest and grandest monuments are the ones he built himself—the great works all over the world employing some sixty thousand workmen and two hundred million dollars capital.

Mr. Westinghouse was in every sense a thoroughly practical man. He knew how to manage men and how to handle tools with his own hands. In going through his great shops with him I have many times seen him stop and show the workmen that what they were doing was wrong, and then he would take hold and show them the right way. Workmen always respect such an employer.

He cared little for music, art or amusements. His favorite recreation was the working out of some new mechanical problem. Many a night after spending the evening with his guests I have known him to work until the small hours

of the morning with pencil and paper over some new idea that had come to him.

He was given many honors both at home and abroad—among the principal ones are the Legion of Honor of France, The Royal Crown of Italy and the Leopold of Belgium. He has been awarded the John Fritz medal and the Edison medal, and just lately the Grashof medal from Germany. He was honorary member and past president of the American Society of Mechanical Engineers, and honorary member of the American Association for the Advancement of Science.

He was one of the most lovable of men, always the same, a perfect gentleman. He was the soul of honor. His private life was pure. His honesty and integrity were unquestioned. During an intimate acquaintance of 47 years I never heard from any one any statement that reflected in any way upon his honesty or his upright character. I think without question he will go down through history as a peer for high character among business men of his time. His home life was ideal. His good wife was never forgotten either when he was at home or when absent, and every evening at a pre-arranged time, unless the ocean separated them, the telephone was always brought into use for their evening greetings. He was preeminently a true and devoted husband to his dear wife and a loving father to his idolized son. His family and all of his friends will feel their loss in his death more and more as the years go by and they will realize that never in this life will they find his equal.

S. T. WELLMAN

CLEVELAND, OHIO,
April 6, 1914

BIOLOGICAL STATION WORK AT THE UNIVERSITY OF WISCONSIN

THE University of Wisconsin will open its biological station to investigators from June 15 to October 1, 1914. During the regular university summer session, courses will be offered in general zoology, general botany, heredity and eugenics, evolution, field zoology, teaching of zoology, dendrology, morphology of algæ,

mosses and ferns, morphology of algæ, seed plants, plant physiology.

Professor M. F. Guyer will have charge of the zoological laboratories, Professor A. S. Pearce will give the field work. Mr. Nathan Fasten and Mr. A. R. Cahn will assist in the general zoological and field courses. Professor H. R. Denniston will direct the botanical work, and the other instructors in this department will be Professor E. M. Gilbert, A. Stewart, W. N. Steil, E. T. Bartholomew, H. E. Pulling and J. P. Bennett.

The city of Madison is admirably located for a biological station. It is surrounded by three beautiful lakes and the adjacent country affords a variety of swamps, marshes, streams, woodlands and prairies. The station therefore offers excellent opportunities for outdoor biological work with all the advantages that go with the equipment of a large university.

For years surveys and investigations on the lake flora and fauna and their conditions of life have been in progress under the auspices of the Wisconsin Biological and Geological Survey, which has its headquarters in the biological laboratory at the university, and the result of these studies will prove of great value to all who are interested in limnology.

A thirty-foot launch capable of carrying a class of twenty-five has just been purchased and will be in commission throughout the summer. An adequate equipment of row boats, nets, seines and other limnological apparatus is also available.

PACIFIC ASSOCIATION OF SCIENTIFIC SOCIETIES

THE fourth annual convention of the Pacific Association will be held at the University of Washington, May 21-23, 1914. The following are the constituents and their secretaries:

Technical Society of the Pacific Coast, Otto von Geldern, 865 Pacific Bldg., San Francisco.

The Cordilleran Section of the Geological Society of America, G. D. Louderback, University of California.

The Seismological Society of America, S. D. Townley, Stanford University.

Pacific Coast Branch of the American Historical

Associations, W. A. Morris, University of California.

The Pacific Slope Associations of Economic Entomologists, W. B. Herms, University of California. Pacific Coast Paleontological Society (special meeting), C. A. Waring, Box 162, Mayfield, Cal.

The Philological Association of the Pacific Coast, G. Chinard, University of California.

The Cooper Ornithological Club (not meeting), T. S. Storer, University of California.

California Academy of Sciences (not meeting), J. W. Hobson, 343 Sansome St., San Francisco.

Biological Society of the Pacific Coast, H. B. Torrey, Reed College, Portland.

California Section of the American Chemical Society, B. S. Drake, 5830 Colby St., Oakland.

Astronomical Society of the Pacific Coast (not meeting), D. S. Richardson, 748 Phelan Bldg., San Francisco.

The Geographical Society of the Pacific (not meeting), J. Partridge, 316 Bush St., San Francisco.

Puget Sound Section of the American Chemical Society, R. W. Clough, 4145 Arcade, Seattle.

San Francisco Society of the Archeological Institute of America (not meeting), O. M. Washburn, University of California.

San Francisco Section of the American Mathematical Society, Thos. Buck, University of California.

The following societies will also meet with the Pacific Association:

Seattle Society of the Archeological Institute of America.

The Oregon Section of the American Chemical Society and the Inter-Mountain Section of the American Chemical Society will join with the Puget Sound and San Francisco Sections.

The LeConte Club will hold its annual meeting and dinner.

Political Scientists will hold a meeting for a program and for the preliminary steps in the organization of a Pacific Coast Branch of the American Political Science Association.

The Northwest Society of Engineers will participate in the meeting of the Technical Society of the Pacific Coast.

The Northwest Association of History, Government and Economic Teachers.

Friday evening will be devoted as usual to the dinners of the constituent societies. Saturday evening will be devoted to the general session of the Pacific Association. At this meeting an address of welcome will be given by

Acting President Henry Landes, of the University of Washington, and three papers of a general scientific interest will be given by three members of the constituent societies.

The railroads have granted the usual convention rates for the convention covering the states of California, Oregon, Washington, Idaho and British Columbia.

The proposal for the transfer of the Pacific Association to the American Association for the Advancement of Science as its "Pacific Division" made at the Berkeley meeting in 1913 resulted in the appointment of committees to consider the plan. During the year the two committees have been at work; the general policies and plans of merging have been agreed upon, and at present a smaller committee is drafting a constitution. It is hoped that the transfer can be made at the Seattle meeting.

SCIENTIFIC NOTES AND NEWS

DR. W. W. KEEN, of Philadelphia, has been elected president of the Fifth International Congress of Surgeons to be held in Paris in 1917.

THE Bruce Medal of the Astronomical Society of the Pacific has been awarded to Dr. O. Backlund, of Poulkova.

THE septennial award under the Acton Endowment has this year been made by the Royal Institution to Professor C. S. Sherrington, Weyneflete professor of physiology in the University of Oxford, for his work on "The Integrative Action of the Nervous System."

AFTER twenty-one years of connection with the Yerkes Observatory, Sherburne Wesley Burnham, professor of practical astronomy, will retire from active service on July 1.

THE seventieth birthday, on March 25, of Professor Adolf Engler, the director of the Royal Botanic Garden and Museum at Dahlem, near Berlin, was celebrated in the presence of many eminent German and foreign botanists, by several functions. According to the account in *Nature*, on the day itself, Professor Pax, rector of the University of Breslau, with Professors Diels and Gilg, as its editors, presented to Professor Engler a copy of the

Fest-Band of Engler's "Botanische Jahrbücher." The volume forms a supplement to the fiftieth volume of this publication, and consists of more than forty illustrated contributions, largely from his pupils. Professor Haberlandt presented Professor Engler, on behalf of hundreds of subscribers, with his life-size marble bust, the work of the sculptor, A. Manthe. On March 26 there was a banquet at which the official world was represented; and on March 27 the monthly meeting of the Deutsche Botanische Gesellschaft was converted into an "Engler" meeting, and Professor von Wettstein gave, by special invitation, a lecture on the phylogenetic evolution of the Angiosperm flower.

DR. JULIUS KOLLMANN, professor of anatomy at Basle, has celebrated his eightieth birthday.

DR. G. T. BEILBY, Professor A. Keith, F.R.S. and Mr. J. Swinburne, F.R.S., have been elected members of the Athenæum Club for eminence in science.

S. ALFRED MITCHELL, Ph.D., director of the McCormick Observatory at the University of Virginia, has been appointed Ernest Kempton Adams Research Fellow of Columbia University for 1914-15. Professor Mitchell is carrying on work in the measurement of stellar parallaxes by the photographic method.

PASSED ASSISTANT SURGEON MARSHALL GUTHRIE, U. S. Public Health Service, has been appointed chief quarantine officer for the Panama Canal Zone.

SIR HOWARD GRUBB, F.R.S., has been appointed scientific adviser to the Commissioners of Irish Lights, in succession to the late Sir Robert Ball, who held the position for the past twenty years.

SURGEON JOSEPH H. WHITE, of the U. S. Public Health Service, now stationed in New Orleans, has been given a leave of absence for one year to take up for the Rockefeller Commission, the work of the eradication of hookworm disease in Central and South America.

THE Jacksonian Prize of the Royal College of Surgeons for 1913 was awarded to Mr. J.

Howell Evans, F.R.C.S., for his essay on malformations of the small intestine. The subject for the year 1915 will be "Congenital Dislocations of the Joints."

PROFESSOR NORMAN WILDE, head of the department of philosophy and psychology at the University of Minnesota, has been granted a year's leave of absence. Professor David Swenson will act as chairman of the department during Professor Wilde's absence.

DR. LEO M. BAEKELAND has been appointed first lecturer upon the Charles Frederick Chandler foundation of Columbia University. Dr. Baekeland's lecture will be given at the University on May 29 in connection with the celebration of the fiftieth anniversary of the founding of the School of Mines.

PROFESSOR BERGSON began his Gifford Lectures on "Human Personality" in Edinburgh on April 21.

A LECTURE on "Kilauea in Action" was given to the Sigma Xi Society of Case School of Applied Science, Cleveland, Ohio, on April 6, by Dr. A. L. Day, director of the Geophysical Laboratory at Washington, D. C.

PROFESSOR FRANCIS E. LLOYD, of McGill University, delivered a lecture on the subject "The Artificial Ripening of Fruit," on April 4, before the Royal Canadian Institute of Toronto; and, on April 14, before the Clinical Society of the Western Hospital of Montreal on "Colloids and the Ultramicroscope."

DR. SHOSUKE SATO, president of the College of Agriculture of the Northeast Imperial University of Japan, is giving his series of lectures on "Fifty Years of Progress in Japan" at the University of Illinois during the two weeks from April 14 to 24. Dr. Sato, it will be remembered, is the second lecturer from Japan in the exchange of lecturers between the United States and Japan.

ON March 27, Mr. N. S. Amstutz, research engineer, Valparaiso, Indiana, lectured to the Civil Engineering Society of Valparaiso University on photo-telegraphy.

AT intervals of two weeks during the months of February and March, Dr. W. P. Kelley, of

the Hawaii Experiment Station, delivered a series of four lectures on soils and soil fertility before the agricultural students of the College of Hawaii at Honolulu.

A BRONZE medallion of the late Dr. John S. Musser, the work of Dr. R. Tait McKenzie, was unveiled in the University of Pennsylvania Hospital on April 15. Dr. George E. de Schweinitz made the presentation address.

THE students and members of the faculty of New York University and Bellevue Medical College held a memorial service in honor of Dr. Egbert Le Fevre on April 5. Addresses were made by Drs. George Alexander, Elmer Ellsworth Brown, Abram A. Smith, George D. Stewart, Edward D. Fisher and Professor John A. Mandel. Resolutions were passed in recognition of the high esteem in which Dr. Le Fevre was held.

PLANS are being made to erect in Lincoln Park, Chicago, a monument in memory of Dr. Nicholas Senn, the distinguished physician.

A PORTRAIT of James Gates Percival, Yale, '15, the poet and geologist, has been presented to Yale University by Harvard University.

ALFRED NOBLE, chief engineer of the Pennsylvania Tunnel and Terminal Railroad Company and a former President of the American Society of Civil Engineers, has died at the age of seventy years.

DR. S. M. JØRGENSEN, director of the Carlsbad laboratory for chemistry and plant physiology has died in Copenhagen, at the age of seventy-six years.

DR. JACQUES HUBER, director of the Musen Goeldi, Pará, Brazil, died on February 18, in his fifty-sixth year.

THE death is announced, at the age of eighty-one years, of Mr. G. Sharman, for more than forty years paleontologist to the Geological Survey of Great Britain.

THE Honorable Francis Albert Rollo Russell, known for his contributions to meteorology, died on March 30, aged sixty-five years.

Nature says: "By the death of Mrs. Huxley on March 5, in her eighty-ninth year, an-

other link with the scientific society of the latter half of the nineteenth century has been snapped. All who had the happiness of knowing Huxley intimately are aware of the reliance which he at all times reposed on the advice and judgment of his lifelong helpmate. Not only in all domestic concerns, but in questions of literary criticism and even of scientific procedure, he never took a step without consulting her, and her wide knowledge and keen literary instincts made her aid invaluable to him." Mrs. Huxley wrote poems and stories, and prepared a selection from Huxley's writings, "Aphorisms and Reflections from the Writings of T. H. Huxley."

THE U. S. Civil Service Commission announces an examination for associate physicist, qualified in engineering, to fill a vacancy in the Bureau of Standards at Pittsburgh, Pa., at a salary ranging from \$2,200 to \$2,700 a year, and a vacancy in the Bureau of Standards, at Washington, D. C., at a salary ranging from \$2,200 to \$3,000 a year.

THE money subscribed in connection with the jubilee celebration of Dr. A. Auwers has been handed over to the Berlin Academy for the foundation of a Bradley Prize, to be awarded once every five years.

WE learn from *The Scottish Geographical Magazine* that the first number of the *Zeitschrift für Vulkanologie*, edited by Herr Immanuel Friedlaender of Naples, and devoted to problems connected with volcanoes or volcanic action, and to appear at irregular intervals, has been issued. In his preface Mr. Friedlaender explains that he has been endeavoring for some years to found an international volcanic institute at Naples, but has met with many difficulties, financial and other. He has therefore established a private institute on a modest scale, and in connection with it is issuing the new journal, which is to contain both original contributions and summaries and abstracts, etc. The first number contains several original papers, the four languages of English, German, Italian and French being all represented. There are a number of fine illustrations, both of Vesuvius and of other volcanoes.

THE interest that has recently been manifested in radium has created a public demand for information both practical and theoretical in regard to the mineral deposits from which it is derived. A short report by Edson S. Bastin on the "Geology of the Pitchblende Ores of Colorado," recently issued by the U. S. Geological Survey, deals mainly with the geology, mineralogy and origin of these deposits, their practical utilization having been treated somewhat fully in other publications. The quantity of uranium ores mined in the United States is exceedingly small, and the great bulk of it, from Utah and southwestern Colorado, does not carry pitchblende but contains the brilliant yellow uranium mineral carnotite. The small pitchblende production of this country is all from the one locality described in this report, in the heart of Gilpin County. It occurs as a constituent of mineral veins which were first worked for their gold and silver content and which still yield important amounts of these precious metals. It is notable that the only other localities in the world where pitchblende has been found in important quantities in mineral veins are the Erzgebirge (in Bohemia and Saxony) and the Cornwall district (in England). Its mode of occurrence in these countries is also described by Mr. Bastin.

ARRANGEMENTS have been made between the New York State College of Forestry at Syracuse University and the Palisades Inter-state Park Commission whereby the college will prepare and carry out a plan of management for the 14,000 acres of forest land controlled by the commission and lying along the Hudson River. The work of getting the forest land into shape will be started about the middle of August by four advanced students under the direction of Professor Frank F. Moon, of the College of Forestry, who was forester for the former Highlands of the Hudson Forest Reservation. The various properties will be mapped out and cruised to ascertain the amount of timber now standing and the amount to be removed. In addition, the fire problem will be studied and eventually a long term reforesta-

tion plan put into force. Centers of insect and fungus damage will be located and timber will be marked so that during the coming winter the park employees will be busy removing the dead, diseased and undesirable specimens. A forest nursery will be developed and active reforestation begun in 1914.

THAT balsam fir, a tree which a few years ago was considered of little value, is now in demand for pulp wood, is the statement made by the Department of Agriculture in a bulletin just issued on the subject. This demand has been brought about, says the department, by the enormous expansion of the pulp industry during the past two decades, with its present consumption of three and a quarter million cords of coniferous wood and the consequent rise in the price of spruce, the wood most in demand for paper-making. In addition, the department goes on to say, balsam has begun to take the place of spruce for rough lumber, laths and the like, as the price of the latter wood has risen. The chief objection to the use of large amounts of balsam fir in the ground-pulp process of paper-making is said to be due to the so-called pitch in the wood, which injures the felts and cylinder faces upon which the pulp is rolled out. Balsam fir does not have a resinous wood, and the material which gums up the cylinder probably comes from grinding balsam under conditions adapted to spruce wood. Yet from ten to twenty-five per cent., and possibly more of balsam can be used in ground pulp without lowering the grade of the paper produced. It is known that with balsam logs left lying in water over a season this drawback practically disappears. In chemical pulp, produced through the action of acids, these acids are known to dissolve the pitch, and any amount of balsam can be used, though some claim that too much balsam in the pulp gives a paper that lacks strength, snap and character. At the present time, balsam fir furnishes about six or seven per cent. of the domestic coniferous wood used by the country's pulp industry. The tree itself constitutes, numerically, about twenty per cent. of the coniferous forest in northern New York

and Maine, and is abundant in many parts of New Hampshire, Vermont, and in the swamps of northern Michigan, northern Wisconsin and Minnesota. It readily reforests cut-over areas, and attains a size suitable for pulp wood in a short time. Under present methods of cutting, balsam fir is said to be increasing in our second-growth forests at the expense of red spruce, and with the gradual decline in the supply of the latter wood the fir will become more and more important commercially.

UNIVERSITY AND EDUCATIONAL NEWS

THE faculty of the graduate school of Cornell University has voted to recommend to the board of trustees that Dr. J. E. Creighton, professor of logic and metaphysics, be elected dean to succeed Dr. Ernest Merritt whose resignation takes effect in June. The recommendation by the faculty is virtually equivalent to election. Two years ago President Schurman, in a report to the trustees, proposed that the faculties of the graduate school and the college of arts and sciences be permitted to choose their own deans and the trustees approved the suggestion. Last year the faculty of the college of arts and sciences did select a dean, in the person of Dr. E. L. Nichols, professor of physics.

DR. GEORGE L. STREETER, professor of anatomy in the medical department of the University of Michigan, has been appointed professor of embryology in the Carnegie Institute of Embryology, of the Johns Hopkins Medical school.

PROFESSOR CHARLES McMILLAN, professor of civil engineering at Princeton University since 1875, has retired and been appointed professor emeritus.

DAVID CAMP ROGERS, Ph.D., associate professor of psychology at the University of Kansas, has been appointed professor of psychology at Smith College.

MR. WILFRED JEVONS has been appointed junior lecturer and demonstrator in physics, and Mr. A. E. Barnes lecturer in materia medica, pharmacology and therapeutics at Sheffield University.

DISCUSSION AND CORRESPONDENCE

PRIORITY OVERWORKED

HAVING personally been a consistent advocate and practiser of the generally accepted rules of priority, for about fifty years,¹ I have no desire to criticize those who have, in recent years, taken up the subject reasonably and temperately, but it is possible in this, as in most other things, to overdo the matter. My objections to some of the recent rulings and applications of the rigid priority rule are threefold:

First: I believe that the rejection of obviously obscene names should be enforced regardless of priority. This has been done by many excellent writers.

Second: Names that have been pirated or stolen from one author by another should be rejected, if the dishonesty can be clearly shown. The cases of this kind are fortunately not numerous, but some are surprising. Such names should not be allowed to pass current any more than counterfeit money or forged checks.

Third: Names of species so badly described that they can not be identified with reasonable certainty should be rejected, especially if no type is preserved. The writings of Linné and other early writers contain many such species. The arbitrary decision of any committee does not alter the case, unless new evidence be given.

To illustrate the second proposition, I will cite a case within my personal knowledge, only omitting names and dates, for obvious reasons, although the incident is not very recent and the parties personally interested are mostly dead.

In this case two eminent and able naturalists and experts, equally interested in the same

subjects, attend the meeting of a learned society. Mr. A. reads a paper announcing the discovery of a remarkable new genus and species, say of vertebrates, giving it a MS. generic and specific name. In the description entirely new anatomical terms had to be defined. Mr. B. listens and takes notes. Within a few days B. publishes, in a scientific journal, the discovery of the identical genus and species as his own, and gives it a new name, with no reference to A. His description precedes that of A. by, say, two weeks. The former description is practically the same as the latter, only abbreviated, and even the same newly coined anatomical terms are used, thus proving that the description was a stolen one. Moreover, it afterwards develops that B. had never even seen a specimen of the creature thus described.

Under such circumstances, would the International Committee decide that the pirated descriptions and false names should be adopted in place of those of the real author?

It would be a delicate matter, perhaps, for colleagues to place before the committee requisite evidence in such a case, if recent; but if it were done, what would be the decision? Evidently under the rigid rules of priority, the names given by B. would be upheld, and later on A. would be wrongly accused of copying from B. and changing his names!

Such things have happened more than once, as many zoologists know. Again, suppose that Professor X. is monographing a large collection, say of insects, in his laboratory, to which his assistants and students have access, as is usually the case, and that one of the young men, Mr. Y., looks over his notes, lists or preliminary labels, and then publishes, without permission, the new names of genera and species in some unimportant local list of his own, without descriptions or figures, merely saying that "Professor X., in his forthcoming work, is going to describe such and such genera, with this and that species as types"; and suppose, further, that when Professor X. does publish his work he does not recognize the previous work, and uses entirely different types for the same generic names. Whose

¹As an evidence of my earlier sentiments, I would call attention to the fact that in 1869 (*Am. Jour. Science*, Vol. XLVII., pp. 92-112), I reprinted the 1845 British Association "Rules of Zoological Nomenclature," with personal notes and suggestions, as footnotes, nearly all of which have been subsequently approved. See also same *Journal*, Vol. III., 1872, p. 387.

names, in such a case, should be adopted? Mr. Y. has pirated the names, but they are in print and have priority. My opinion is that they should be rejected as stolen goods.

This is not an imaginary instance, and such cases have happened more than once. Mr. Y., in such a case, may be thoughtless, rather than criminal, but the resulting confusion in nomenclature is the same.

It seems to me that the case of Fr. Weber, 1795, *versus* Fabricius, 1798, concerning the genera of Crustacea, is a case of just about this sort, yet the committee has decided in favor of the obscure and rare pamphlet of Weber, as against the important work of Fabricius, from whom the generic names were apparently stolen, or improperly borrowed, for Fabricius did not adopt or recognize many of the genera in the forms prematurely published. To adopt the pirated generic names is to throw crustacean nomenclature into much confusion.

If the unauthorized publishing of scientific names is to be upheld as valid, then a reporter for any newspaper or magazine who chooses to report technical papers and note down the names used in a meeting of a learned society may have to be quoted as the author of the names, whether rightly or wrongly spelled. I could give cases of this kind, but it is best to forget them, no doubt, for somebody might revive them, as valid publications.

To illustrate the first and third propositions we may take up an article by Professor J. Playfair McMurrich, "The Actinaria of Pasamaquoddy Bay, with a Discussion of Their Synonymy."²

In this article the author tries to restore certain names given by Linné to some obscure Norwegian species, in place of those almost universally adopted by European and American writers for some of the best known species common to both coasts.

He brings forward no evidence that has not been well known to nearly all writers on the subject. He himself admits that the descriptions given by Linné are insufficient to identify any species, and he therefore depends on

the references made by Linné later (in edition XII.) to various earlier writers, as was his habit in many groups. Every one familiar with his work must recognize that he often made such references very loosely, mainly to give some general idea of the looks of a thing, without intending to imply absolute identity. McMurrich picks out certain figures, among several referred to by Linné, that he thinks can perhaps represent the species intended, but he rejects various others, and thus guesses at what Linné had in mind, even when the figures disagree with the descriptions.

In fact, Linné was profoundly ignorant in respect to most marine Invertebrates, except shells. His descriptions of Actinians are no better than an intelligent boy twelve years old could write, after five minutes of watching these creatures, and his references to figures are as careless as his descriptions. Therefore his actinian species should be dropped as indeterminate, even if there were no other good reasons. The leading European authorities, familiar with the actinians of the same region, have never been able to agree as to his species, and they surely ought to have an advantage over an American in such matters.

But this is not the only reason why most writers, before McMurrich, have wisely rejected the names. The most convincing reason has been their obscurity. No writer has been more familiar with north European actinians than P. H. Gosse. In his "Actinologia Brit.," 1860, he quotes both *A. senilis* and *A. judaica* of Linné under *A. dianthus*; and also *A. senilis* and *A. felinia* under *Tealia crassicornis*. But he dismisses these names as entirely "out of the question," on account of their objectionable significance.

Linné gave obscene names to some genera and to many species. These, in many cases, were merely the dirty names given to many marine creatures by the local fishermen and put into a Latin form by Linné or his predecessors. Such obscene names (often the same) are still in use, even by American fishermen, as I know from long experience.

² *Trans. Royal Soc. Canada*, Vol. IV., 1911, p. 59.

Once, when I asked the captain of a Cape Ann fishing schooner what names they gave to certain actinians, holothurians, ascidians, etc., he said, "We should not dare to tell our wives and daughters," and I agreed with him. Such are the names that McMurrich and some others would like to revive!

It is rather embarrassing, when asked by an educated lady the name of a beautiful sea-anemone, to have to say that its name is "*Priapus senilis*," or even *Metridium senilis*; or "*Priapus humanus*" Linné, for another creature; or to give other equally unjustifiable names.

That Linné used these and other names in an obscene sense is evident, not only because often derived from fishermen's dirty names, but because he described his species in the terms of human anatomy of sexual organs, in many cases, too absurd to mention.

It is, therefore, unfortunate that a zoologist of such excellent ability as Professor McMurrich, should waste his time trying to revive these old, dirty, indeterminate names, which he himself admits can not be definitely applied to any species by means of the descriptions themselves, while his indirect evidence is equally uncertain. The names that he thus adopts are *Metridium senilis* for *M. dianthus*; *Urticina felina* for *U. crassicornis*; *Priapus equinus* for *Actinia mesembryanthemum*.

In the tenth edition of the "Syst. Nat.," 1758, p. 656, the two species of "*Priapus*" are *P. equinus* and *P. humanus*. The latter is a sipunculoid worm. I do not know that any one has recently tried to revive this name. It has better claims than some of the others.

For *P. equinus* the only description (1758) is "semiovalis læviusculus." Surely not very edifying! In Fauna Suecica, p. 510, he has three more species: *P. senilis*; *P. judaicus*; *P. felinus*. The first has, as a diagnosis, only this: "subcylindricus rugosus," with a three-line descriptive note, to the effect that it is the size of the last joint of a finger; that it is fuscous, sordid, rough, with a subcoriaceous tunic, with the upper part soft, thin and sanguineous. These characters surely do

not apply to *M. dianthus*, which is large, soft and smooth throughout, and especially delicate and translucent, when as small as the one mentioned by Linné. It does not have the upper part sanguineous, however much it may vary in color. There are other species on the Norwegian coast that agree with the brief description far better. This identification by McMurrich is then in itself untenable, as well as undesirable.

As for "*Priapus felinus*," 1761, the case is no better. The diagnosis is "cylindricus lævis glande muricata." The descriptive note is "simillarius priori," "sed glande muricata." No reference to earlier works. What he means by a "muricate glans" is hard to understand, if he had a soft actinian before him, like *Actinia mesembryanthemum*. Perhaps he refers here to another sipunculoid worm.

As for the generic name *Priapus*, 1758, if it is to be used at all, it must be applied to the second species, *humanus*, as the type, for the first species was very early (1767) placed in *Actinia*. Whether helminthologists will adopt the name remains to be seen.

A. E. VERRILL

THE EDUCATIONAL VALUE OF MATHEMATICS

TO THE EDITOR OF SCIENCE: In a speech before the Cincinnati Schoolmaster's Club on February 21, 1914, Professor E. L. Thorndike, of Columbia University, made certain statements with regard to the educational value of mathematics and the classical languages, which were quoted in the issue of the *Cincinnati Enquirer* for February 22. One of the statements as quoted was that the old notion that Latin or mathematics made the mind more effective in all the work of business, law or other professions was largely superstition.

The phraseology of this statement is certainly misleading. By the use of the expression "old notion" Professor Thorndike tends to convey the impression that no up-to-date, intelligent person has such a notion. That this is the very reverse of the truth may be seen by quoting from an article by Professor C. J. Keyser in the issue of SCIENCE for

December 5, 1913, entitled "The Human Worth of Rigorous Thinking." Professor Keyser is the head of the department of mathematics at Columbia University, Professor Thorndike's own institution, and is a writer of international repute on mathematical subjects and particularly on the educational value of mathematics. I leave it to any one to judge as to who is better qualified to speak with authority on the subject of mathematics and the pedagogy of mathematics, Professor Thorndike or Professor Keyser.

Professor Keyser says in the course of his paper:

We are beginning to see that to challenge the human worth of mathematics, to challenge the worth of rigorous thinking, is to challenge the worth of all thinking, for now we see that mathematics is but the ideal to which all thinking, by an inevitable process and law of the human spirit, constantly aspires. We see that to challenge the worth of that ideal is to arraign before the bar of values what seems the deepest process and inmost law of the universe of thought. Indeed we see that in defending mathematics we are really defending a cause yet more momentous, the whole cause, namely, of the conceptual procedure of science and the conceptual procedure and activity of the human mind, for mathematics is nothing but such conceptual procedure and activity come to its maturity, purity and perfection.

If Professor Thorndike had read Professor Keyser's paper, of which I have only quoted a brief extract, I doubt if he would have characterized as "superstition" ideas which are so vigorously maintained by one of the men best qualified to speak with authority on the subject in question.

Another statement by Professor Thorndike is that

Mathematics improves mathematical reasoning but not the power to reason in general.

I am yet to be convinced that there is more than one kind of reasoning; whether one reasons in mathematics or in some other subject, he is going through the same process. Mathematics furnishes the best training in reasoning because the student is required to reason more frequently than in any other subject, and

because he is always in a position to test the validity of his reasoning by means of exact concepts.

However, I am not writing this letter because the opinion of some of the educational faddists of the day with regard to the educational value of mathematics is a matter of much significance to a mathematician, in itself. I *am* writing it in defense of a rational curriculum in the high schools and the elementary schools. Having received my own preliminary education in the Cincinnati schools, and having had considerable opportunity of late to observe the preparation of students entering college from this community as compared with that preparation some fifteen years ago, I can only deplore the modern tendency to give at most a superficial attention to fundamental subjects, and to divide the student's energy and attention among a multitude of subjects in such a manner as to create in his mind hopeless confusion and to prevent his having really definite ideas about anything in particular.

The teachers in the high schools and the elementary schools are working just as hard as ever, are just as efficient as ever, but they can not obtain as good results under the handicap of present-day curricula. The student can not be trained to think in as effective a manner as he was fifteen or twenty years ago, under present circumstances. And I believe any reasonable person will agree that the primary object of education is to teach the student to think, whether he is going to enter college or is going out into the world at the end of his high-school course.

But those who have been most responsible for this unfortunate state of affairs in the high schools and the elementary schools, far from realizing the work of destruction that they have already done, are now endeavoring to complete it by attacking what is left of valuable educational training in the curricula of to-day. It is high time that those who see the danger of this movement, and I know there are many, make a resolute stand against it. If such statements as those of Professor Thorndike are allowed to go unchallenged, and thus

to appear to the general public as having the weight of authority behind them, there is no telling where we shall be before the inevitable reaction sets in.

Personally I believe that every student who takes a four year course in high school should be required to study the English language during those four years, and at the same time he should be getting some definite knowledge of either mathematics or the classical languages, preferably of both. Distinct vocational training might well be left in the background until the student has had an opportunity to get some real mental training. I know this is the opinion of the great majority of my colleagues at the University of Cincinnati, including Dean Schneider, of the college of engineering, who is a recognized expert on vocational training. And I do not doubt that it is the opinion of the great majority of college teachers throughout the country.

CHARLES N. MOORE

UNIVERSITY OF CINCINNATI

SEX IN MULTIPLE BIRTHS

In a copy of lectures delivered by Dr. Raymond Pearl at the 1912 Graduate School of Agriculture at Lansing, Mich., I find the following tables given, indicating that in multiple mammalian births as the numbers per birth increase, the ratio of males to females decreases.

<i>Man</i>			
No. Young per Birth		Males per 1,000 Females	
1		1,057	
2		1,043	
3		548	
<i>Sheep</i>			
3 Males; 2 Females			
3 Males	1 Female	1 Male	3 Females
16	39	22	38

In the sheep there are 215 females to 130 males.

It is worthy of note that these data are from normally uniparous species. In swine where the number at a birth may vary from one to twenty-three (in an exceptional instance) this excess of females is not apparent. In 174 litters the number of males per litter

and the expectation based on chance, using the relative frequency of the different-sized litters (fourteen per litter being the largest) was as follows:

No. Males									
per litter.....	0	1	2	3	4	5			
Expectation ..	3.4	12.8	24.6	33.4	34.7	28.5			
Actual	2	13	26	28	31	28			
No. Males									
per litter.....	6	7	8	9	10	11			
Expectation ..	19.0	10.4	4.6	1.7	0.48	0.11			
Actual	21	12	8	2	2	1			

This shows but a slight departure from expectation and is within the limits of error for such small numbers. It seems doubtful if there is a tendency toward increased proportions of females in multiparous births. In fact the excess is slightly on the male side here.

In 126 births from various private collie, fox terrier, Scottish terrier and Boston bull terrier records, the following results appear:

No. male pups ...	0	1	2	3	4	5	6
Expectation	15.1	35.75	37	24.5	10.86	2.8	.3
Actual	14	36	39	22	11	4	0

These statistics give qualitatively the same result. That this accordance with expectation on the basis of chance is not necessarily a property of normal multiple births, is shown by the following statistics on sheep triplets from the Iowa State College flock and two farmers' flocks located near there. The total number of lambings is 146.

	3 Males	2 Males; 1 Female	1 Male; 2 Females	3 Females
Expectation...	18.25	54.75	54.75	18.25
Actual	21.00	56.00	51.00	18.00

This gives 226 males and 212 females. The smallness of these numbers does not conclusively indicate that influences other than mere chance do not operate, but they are interesting since they give opposing evidence on the point discussed by Dr. Pearl.

SCIENTIFIC BOOKS

Biochemie der Pflanzen. Von Dr. FRIEDRICH CZAPEK, Professor der Anatomie und Physiologie der Pflanzen an der K. K. Deutschen Universitaet in Prag. Zweite, umgearbeitete Auflage. Erster Band, pp. xix., 828, mit 8 Abbildungen im Text. Verlag von Gustav Fischer, Jena, 1913. M. 24.00, geb. M. 25.20.

In reviewing a recent foreign treatise on organic chemistry, one of our best chemists, who is also very favorably known as an investigator, made the remark that it was so much more difficult to teach organic chemistry to-day than it was a generation ago, apparently for the reason that the field to be covered is so much greater now than it was then. Recently a graduate student, who was attending a course of lectures on organic chemistry by way of review, made the statement that in the course of his college career he had heard a number of organic chemists lecture and that while their method of presenting the subject differed in each case, the lecturer had invariably introduced his topic by stating that he did not expect his students to learn something about each of the hundred thousand and some odd tens of thousands of organic compounds catalogued in Beilstein and its supplements. It would seem that some of the horror which so many students experience, or at least feign to experience, at the number of organic compounds when they first approach the subject, is due in part at least to their teachers. While we profess that we are not frightened by the numbers of carbon compounds and inform our students at the outset that they need not be horror-stricken by any such mass action, yet we seem to feel, and even proclaim that, because of the enormous strides made by organic chemistry, we need more time than formerly to cover the ground though but in an elementary fashion. If, *e. g.*, we measure the growth of organic chemistry by the ten thousand or more carbon compounds that have been added to our catalogue in a given period, then indeed our point of view must

make us pessimistic as to the ultimate outcome of our success as teachers of the elementary part of our subject in any rational allotment of time at our disposal during the college quadrennium.

Any organic chemist who has reached middle age may well appreciate the mental state of chemists of the old school who found themselves confronted by Kekulé's structural theory. But, if they were confounded it was due, not so much to the rapid growth in the number of compounds that resulted from the application of Kekulé's views, as from the different mental attitude that the structural theory demanded. The Grignard reaction, though in short space it has produced thousands of new compounds at a time when the progress in organic chemistry was referred to as having become sluggish, wrought no visible disturbance whatever for the simple reason that it brought no new fundamental theories into play, hence made no demands on our mental attitude toward the subject. Any one who has studied the life of Liebig carefully must have noticed that underneath the surface there was something more than dissatisfaction toward the university administration that caused him to leave Giessen. The theory of substitution was revolutionizing organic chemistry in spite of Liebig's attitude and in spite of the "S. C. H. Windler" which Woehler hurled at the French chemists. But whereas Woehler adapted himself as well as he could and stuck to his post and his "Fach," Liebig found it more convenient not only to migrate, geographically speaking, but to "umsteigen"—if this apt expression by Mark Twain may be permitted in so serious a topic as this—or to "umsatteln" if a German phrase when applied to the change of a German chemist from the pure to the applied seem preferable.

The structural development of organic chemistry has made it possible to treat the subject-matter deductively rather than inductively. The claim of inductive treatment in science has become a sort of fetish. We have preached this doctrine to such an extent to our students that we dare not admit that

our method of procedure after the first or second lecture is largely deductive. If in organic chemistry we have the courage to be outspokenly deductive from the start and insist on its logical consequences, half of the battle is won. To be sure there are still a sufficient number of difficulties to be overcome, but they do not consist in numbers, but rather in the possibility of acquiring the right mental attitude.

To a large extent plant chemistry is organic chemistry. However, whereas most of the new organic compounds that are produced synthetically find a convenient place in the well-regulated drawing room of organic chemistry, most of the new substances isolated from the vegetable kingdom—and many of the old timers from the same source—still belong to the lumber chamber of organic chemistry.

It is true that organic chemistry consists of something more than the study of the physical and chemical properties of chemical individuals containing all the way from one to a host of carbon atoms. Modern organic chemists with adequate physico-chemical training appear but too anxious to rub this fact into their older colleagues. This is equally true of the organic chemistry of the vegetable kingdom, but to a much greater degree. The "Grundlagen und Ergebnisse der Pflanzenchemie" by Euler, one part of which consists of a briefly descriptive catalogue of the *materia phytochemica* and two parts of which are a text on physical chemistry with occasional phytochemical application, are but a partial expression of the truth of the above assertion. Great as has been the development of physical chemistry, more particularly since Ostwald "made school" at Leipzig, it has scarcely begun to explain the problems of the "Biochemistry of the Plants," though it has touched upon this subject at innumerable points. Whereas the application of structural chemistry to the *materia phytochemica* has made possible a large amount of systematization and has thus simplified the situation, physical chemistry has thrown but dim light on innumerable spots. The status of the ap-

plication of physical chemistry to biochemical problems is approximately that of the status reached in organic chemistry when Berzelius characterized the discovery of the benzoyl radicle by Liebig and Woehler as the dawn of organic chemistry. Daylight is beginning to dawn in the study of biochemical problems, but before daylight appears much more generalization will have to be made possible, not only by the extension of present physico-chemical methods over a large field, but by a much better understanding in each and every department of biochemical research. The single chapter of catalysis, always a convenient word to cover our ignorance, and its application to enzyme action is sufficient illustration.

To attempt to write a comprehensive biochemistry of plants under present conditions is a stupendous undertaking. The mere cataloguing of the constituents of plants as attempted by Wehmer in his "Pflanzenstoffe" for the Phanerogams has proved sufficiently burdensome to discourage even the most ardent compiler. Hence one is not surprised to learn that Czapek has gladly availed himself of the opportunity to unload a part of this work, as undertaken in the first edition, by referring his readers to Wehmer for more complete data so far as the constituents of phanerogams are concerned. Yet in spite of this limitation, the first volume has grown enormously. If it is more of a true biochemistry than was the corresponding volume of the first edition, this is due not so much to this sort of unburdening as it is due to the greater attention and more space given to general considerations. Readers of this review who have been accustomed to resort freely to the first edition for information may be interested to compare the figures given in the following outline of the contents of the second edition with the corresponding figures of the first. At the same time the following data will give a better idea of the contents to those not already acquainted with Czapek.

Preceded by a short historical introduction of nineteen pages, the contents of the volume are classified under two general heads, viz.,

General Biochemistry (pp. 20 to 240) and Special Biochemistry (pp. 240 to 820). The first part is subdivided into four chapters:

1. The substratum of the chemical changes in the living organism, the protoplasm (pp. 20 to 65).

2. The chemical reaction in the living plant organism (pp. 66 to 146) including such topics as the conditions of the reactions, the time element, catalysis, enzymes, immunity.

3. Chemical stimulation (pp. 147 to 233) including growth in all of its aspects.

4. Phenomena of chemical adaptation and inheritance (pp. 234 to 239).

The subject-matter under special biochemistry is arranged into parts, divisions and chapters. Part I. deals with Saccharides and the rôle which they play in plant metabolism (pp. 240 to 708). The "general division" discusses the vegetable sugars. The "special division" takes up the following subjects in as many chapters:

5. The sugars and carbohydrates in fungi and bacteria.

6. The resorption of sugars and carbohydrates by fungi and bacteria.

7. The carbon assimilation and sugar formation by fungi and bacteria.

8. The carbohydrate metabolism in the Algae.

9. The reserve carbohydrates of the seeds.

10. The resorption of sugar and carbohydrates in the germinating seeds.

11. The formation of reserve carbohydrates in the seed.

12. The carbohydrate metabolism in underground reserve organs.

13. The carbohydrate metabolism in shoots and leaf buds.

14. The carbohydrate metabolism in foliage leaves.

15. The carbohydrate metabolism in the reproductive system.

16. The carbohydrate metabolism in phanerogamic parasites and saprophytes.

17. Resorption of carbon compounds by means of the roots and leaves of phanerogams.

18. Secretion of sugar and carbohydrates.

The phytochemical synthesis of sugar in the chlorophyll receives an exhaustive treatment (pp. 506 to 628). The subject of saccharides as skeleton substances of the plant body is similarly treated.

Part II., the last part of the first volume, is devoted to the lipoids in plant metabolism, which subject is treated under two principal heads: the nutritive lipoids and the cytolipoids. Under the former head we find,

22. The reserve fats of the seeds.

23. The resorption of fats during the germination of the seed.

24. The formation of fats in ripening seeds and fruits.

25. Reserve fats in stems, etc., and foliage leaves.

26. Fat as reserve material in thallophytes, mosses, ferns and pollen grains.

Under the head of cytolipoids the following subjects are discussed:

27. Vegetable lecithines (phospholipoids).

28. Vegetable cerebrosides.

29. Sterinlipoids of plants.

30. Vegetable chromolipoids.

31. The production of wax (cerolipoids) in plants.

Thus it becomes apparent that volume one, although it has greatly increased in size, considers but two groups of phytochemical substances and the biological problems which they suggest. If the chemistry of the simple saccharides has been in a fairly satisfactory condition since Fischer paved the way to a better understanding, we must not forget that we have but entered the vestibule of a carbohydrate chemistry and that the problem of the photosynthesis of the simplest sugar has not yet been solved to the complete satisfaction of the physiologist.

It has evidently been the endeavor of Czapek to bring together the available information on a given subject and to classify the information as indicated by the chapter headings quoted above. This manner of treatment does not make a good text-book, but with the extensive references to original literature

it makes an admirable reference book. Czapek has also refused to assume the rôle of arbiter, but quotes, with as little prejudice as can be expected, the opinions of each individual, leaving it to the reader to arrive at his own conclusion.

In closing, a single allusion to the greater importance that is being accorded to phytochemistry in recent years may not be out of place. For more than a generation after the announcement of the benzene theory by Kekulé, organic chemists could think of little else than synthesized substances and of coal tar as their gold mine. So one-sided were they at times that they did not even see the element of the ridiculous in the suggestion to make foodstuffs artificially from this source. The other extreme has now been reached by the pure-food chemist who by big head lines in the newspapers and the waving of red rags before large audiences denounces this same coal tar as the source of everything that is bad. A much more common sense reaction has been started by those chemists who have been pointing out how the intricate process of the plant laboratory may be husbanded for the benefit of mankind by farmers who need not be Ph.D.'s but who have been taught by the biochemist to make the most of their opportunities.

Again, while we should welcome the new synthetic remedies that have been turned out by the "Farbenfabriken" of the fatherland, we should not forget that in this field also the plant still produces valuable remedies which we can obtain as well or better from living or recently dead plants than as a by-product from fossilized plants of former geological ages.

But aside from the agricultural and pharmaceutical or medical aspects which the chemical study of plants and plant life may afford, the study of these subjects for its own sake has a charm all its own. Who can view the beautiful color of the flowers or inhale their perfume without feeling that a knowledge of the processes by which the plant produces these physiological effects on the intelligent animal is in itself worth knowing though the pigment never be used to dye a fiber, nor the

perfume be extracted in order to find a place on my lady's toilet table EDWARD KREMERS

A History of Land Mammals in the Western Hemisphere. By WILLIAM BERRYMAN SCOTT, Blair Professor of Geology and Paleontology in Princeton University. New York, The Macmillan Company, 1913. Pp. i-xiv + 1-693, with frontispiece and 304 text-figures.

In this striking volume Professor Scott has striven to assemble and set before the lay reader a judicious selection from the great accumulation of facts which the many students of mammalian paleontology have discovered. The presentation of the subject is essentially different from that of Professor Osborn's "Age of Mammals" wherein the rise and spread of faunas are treated as a succession of historical events. In the present work, after certain introductory chapters, the treatment is zoological, the life history of each of a number of important orders being discussed from beginning to end. Thus the two works by two of the foremost American paleontologists are supplemental; collectively they give a complete picture of Tertiary time.

The first two chapters of Professor Scott's book acquaint one with the methods pursued by the student of past life, the one showing the way whereby the geological data are interpreted, and the other the methods of paleontological research—how animals are preserved from the remote past, the nature of the remains, the way in which the characters they show are explained, and the method whereby the animal is reconstructed as a living being. A chapter on the principles of taxonomy is concluded by a full mammalian classification which is almost identical with that given by Professor Osborn in the "Age of Mammals," the only differences being relatively unimportant. The discussion of the skeleton and teeth of mammals, so essential to an understanding of fossil evidence, is followed by a chapter on the principles of geographical distribution of mammals and a summary of the successive mammalian faunas.

The succeeding chapters elucidate the histories of the principal orders: the Perissodac-

tyla—horses, titanotheres, rhinoceroses; the Artiodactyla—swine, camels, deer; the Proboscidea; and of the primitive ungulates, the Amblypoda and Condylarthra. There follow a number of chapters devoted to the peculiar South American ungulates, on which Professor Scott is so pronounced an authority, and these give place to a discussion of the carnivores, primates, edentates and marsupials.

Chapter XVIII. is philosophical, in that it expresses very clearly Doctor Scott's ideas concerning the modes of mammalian evolution. He states in explanation of the variations found between the "family trees" that "It is quite impracticable to construct a genetic series without making certain assumptions as to the manner in which the developmental processes operated and the kinds of modification that actually did occur," and the facts upon which these assumptions are based are ascertained by several distinct methods. Of these the oldest is comparative anatomy, an accurate knowledge of which is indispensable to the use of the others. The second is that of embryology, for, while Haeckel's famous biogenetic law, wherein the life history of the individual is supposed to give a résumé of that of the race, is proved not to be implicitly trustworthy for the interpretation of structural features, nevertheless the information attained through study of the embryonic stages is of the greatest service in the solution of zoological problems.

The third method, experimental zoology, especially that part known as genetics, has also taught us much; but the fourth, paleontology, despite the imperfection of the record due to the irretrievable loss of much of the past history of life, nevertheless has the pre-eminent advantage of offering to the student the actual stages of development, as it preserves the original documents and in the true order of succession.

In summation, Professor Scott remarks: "It is only too clear that the principles as to the modes of mammalian development which can be deduced from the history of the various groups must, for the most part, be stated in a cautious and tentative manner, so

as not to give an undue appearance of certainty to preliminary conclusions, which should be held as subject to revision with the advance of knowledge. Much has, however, been already learned, and there is every reason to hope that experimental zoology and paleontology, by combining their resources, will eventually shed full light upon a subject of such exceptional difficulty" (p. 663). A full glossary completes the volume.

The illustrations are in part from photographs of living mammals and clear anatomical drawings of certain essential skeletal features, but what will interest the general reader most are the admirably drawn reconstructions of extinct forms done by R. Bruce Horsfall under the careful supervision of Professor Scott. There are also others by Charles R. Knight, whose work always has a realism which no other artist of the prehistoric has ever attained.

In the production of this work Professor Scott has done a lasting service to the serious student of paleontology, as well as to the lay reader, and it is to be hoped that the admirably conceived and executed volume will have the appreciation it deserves.

RICHARD S. LULL

YALE UNIVERSITY

The Hill Folk. Report on a Rural Community of Hereditary Defectives. By FLORENCE H. DANIELSON, M.A., and CHARLES B. DAVENPORT. Eugenics Record Office. Memoir No. 1.

As explained in the preface, this is the first of a projected series which is intended to embody some of the more extended research of the Record Office. Dr. Davenport calls attention to the fact of its primary value to sociologists rather than to students of inheritance traits—which latter will require much more extended study, which, we are assured, will come later.

This Hill Folk study began with pedigrees of some of the inmates of the Monson State Hospital at Palmer, Mass., and extended to a town of 2,000 inhabitants in a fertile valley on a railroad between prosperous cities. The town is frequented by tourists who about

double the population during the summer. A lime kiln and a stone quarry represent the only industries outside of prosperous farming, that are followed. The Hill Folk descended from two men, a shiftless basket maker, known here as Neil Rasp, and an Englishman, owner of a small farm, both of whom came to the settlement about the year 1800. Their descendants have "sifted through the town and beyond it. Everywhere they have made desolate, alcoholic homes which have furnished state wards for over fifty years, and have required town aid for a longer time."

After an explanation of the charts—which are printed in the circular form with lines of descent radiating from the center and oldest generation—and a general survey of the strains involved and their traits, the following topics indicate the methods of study followed, viz., (a) inheritance, (b) marriage selection, (c) financial burden entailed by criminals and dependents (with a comparison with the Jukes), (d) survey of the present school children and (e) heredity and environment. An appendix takes up a detailed history of the separate families and certain individuals and their characteristics. The usual conventional symbols (American) are employed, though an apparently successful effort has been made to distinguish two degrees of mental deficiency and to indicate the same by the symbols. The members of the higher group, which are indicated by the letter "F" on white background, are able to support themselves in an inefficient "meager way," but "lack ambition, self control, common sense and the ordinary mental and moral capacity for differentiating between right and wrong." The individuals of the lower group, indicated by the symbol on a black background, are incapable of self support and "are a special menace to the community from their lack of all mental and moral stamina."

The symbol "Sx" is applied to the cases only where the "sex impulse works unhindered" from a lack of proper balance between the impulse and self control, as distinguished from those who only incidentally commit a sexually immoral act.

There is considerable data found in this study for comparing the effects of changes of environment.

An excellent lesson is derived from the study of one typical case showing the result of permitting marriage between and propagation of children by a pair of evident defectives. Of eleven children born from this union, all but two, that died in infancy, became public charges. Seven were known to be feeble-minded. Two of these and one of the infants that died early were epileptic.

An exceedingly interesting and instructive study is the survey of seventy-five school children from these families. Of these, school records were obtained in all but seven cases. From these the mental characteristics are noted. Thirty-eight are below the grade in which they should be in the schools, and in general they are either unable to fix attention upon one thing long enough to grasp it or require so much time to comprehend ideas that they progress very slowly. Usually they are "quiet, stupid laggards." The aggressive disturbers of social peace, though present, are the exceptions here.

This study of eight hundred and thirty-seven people has involved an immense amount of work on the part of the field worker, Miss Danielson, and has been subjected to a very searching and critical analysis by Dr. Davenport. It is full of interesting material for comparisons, some of which are discussed by the authors; as, for instance, the effects of dispersion of the feeble-minded groups; the attempt to approach the determination of unit mental characteristics; the ultimate cost of early segregation as compared with its neglect, etc.

The following is a brief summary of conclusions given.

"1. The analysis of the method of inheritance of feeble-mindedness shows that it can not be considered a unit character. It is evidently a complex of quantitatively and qualitatively varying factors most of which are negative, and are inherited as though due to the absence of unit characters.

"2. The value of out-marriage, exogamy, as a means of attenuating defective strains is

diminished by the action of social barriers and the natural preference of individuals, which induce marriages among like grades of mentality, in a foreign as well as a native locality.

"3. The amount of town aid which this one group of defective families requires decennially has increased 400 per cent. in the last thirty years. In the same length of time its criminal bill has been \$10,763.43 for sixteen persons; and the bill for its thirty children who were supported by the state during the last twenty-three years is \$45,888.57. During the past sixty years this community has, it is estimated, cost the state and the people half a million dollars.

"4. Half of the present number of school children from these families who are living at home show evidence of mental deficiency.

"5. One half of the state wards from the community in question have reacted favorably in an improved environment and give promise of becoming more or less useful citizens; the other half consist of institutional cases and those which have not reacted to the better environment, but are likely to become troublesome and dangerous citizens.

"6. The comparative cost of segregating one feeble-minded couple and that of maintaining their offspring shows, in the instance at hand, that the latter policy has been three times more expensive."

Valuable as are the deductions from such a piece of work as this, its greatest value lies in the number of facts collected and recorded, which will always be available for later comparisons in two ways, viz., with any subsequent information concerning the same people, and with collected facts concerning other families and settlement groups as they are being secured in different parts of the country.

A. C. ROGERS

The Microtometist's Vade-mecum. A Handbook of the Methods of Microscopic Anatomy. By ARTHUR BOLLES LEE. Seventh edition. Philadelphia: P. Blakiston's Son & Co. Pp. x+526. 1913.

The appearance of a new edition of this well-known handbook will be welcomed by

biologists, many of whom, like the reviewer, have doubtless awaited its appearance with some impatient anticipation. Although entitled a "Handbook of the Methods of Microscopic Anatomy," the field covered is broad, as there are included methods employed by embryologist, histologist, zoologist and botanist. The need the book aims to meet is thus not a simple one. The extensiveness of the field calls for a careful selection from a large mass of material, of standard methods of real value which need to be worked over and personally tested. This the author has in most instances done and hence the greater practical value of the book.

The present edition conforms to the previous one in arrangement, form of presentation and size—this last despite the addition of considerable new matter ("more than 700 new entries in the index"). Indeed, of the thirty-six chapters that make up the book the only ones which are increased in length are those on Embryological Methods (Ch. XXV.) and Nervous System; Cytological Methods (Ch. XXXIII.). The condensation has been secured by "cutting out superfluous matter, condensation of the text and typographical compression." The sections relating to neurofibrils and to blood and blood parasites the author states in the preface have been almost entirely rewritten. Of important additions to histological technique introduced since the previous edition, the author specifically mentions Gilson's mounting media, camsal balsam and euparal, which permit mounting direct from 95 per cent. alcohol, and also improvements in the Bielschowsky and Cajal silver methods.

As in the previous editions, the methods considered by the author more important are presented in larger type, those less important in small type. The references to the original articles are in all instances given and are, as far as the reviewer has tested them, exact.

It would not be difficult in a book of this kind whose excellence depends upon a rigorous selection and personal emphasis, for a worker to cite methods which might well have been included or which seem to merit more

emphasis, such as Wright's blood stain and Mallory's connective tissue stain, the latter not given in its latest form. Hasting's Nocht's blood stain is not mentioned, nor the value and usefulness of formalin with the freezing microtome. Under embryological methods the modeling methods should perhaps have been given more attention, and to the von Wijhe methylene blue clearing method for cartilage might well have been added others such as the alizarin oil of wintergreen and benzylbenzoate method (Spaltcholtz) and the Schultze caustic potash and glycerin clearing methods for bone and nerves. But when all is said, the emphasis should be placed, not on what has been omitted, but on the large number of standard methods that have been included.

The index is full, cross references are numerous and the typography, paper and binding satisfactory; typographical errors are rare; in fact, the high standard of the sixth edition has been maintained in the present one, which, like those that have preceded it, may be expected to occupy an important place on the table of the practical worker with the microscope in the field of biology.

B. F. KINGSBURY

SEVENTH LIST OF GENERIC NAMES
(TUNICATES) UNDER CONSIDERATION
IN CONNECTION WITH THE OFFICIAL
LIST OF ZOOLOGICAL
NAMES

26. Notice is hereby given of the receipt by the secretary of the Commission on Nomenclature of the following communication regarding generic names of tunicates. All persons interested in the matter are cordially invited to submit to the secretary any arguments for or against the proposed action. In accordance with instructions from the International Congress, the secretary is required to give at least one year's notice to the zoological profession before the Commission takes any action involving the acceptance of any name under the plenary power for suspension of rules.

27. In accordance with instructions from

the Congress, copies of this notice are sent simultaneously, but without comment, to the following journals: *Bull. Soc. Zool. France*, *Monitore Zoologico*, *Nature*, *SCIENCE*, *Zool. Anz.*

Doliolum, *Pyrosoma*, *Salpa*, *Cyclosalpa*, *Appendicularia* und *Fritillaria* sind gegen Aenderung zu stützen.

Wir 12 unterzeichneten Tunicatenforscher sind übereingekommen, die 6 genannten Genusnamen pelagischer Tunicaten als gültig anzunehmen. Die Namen dieser Tunicaten werden von jedem Zoologen als vollkommen eingebürgert anerkannt werden, ihr Gebrauch hat bisher niemals zu Missverständnissen Anlass gegeben, die Genera sind Paradigmata in der zoologischen Systematik, sie spielen in der Entwicklungsgeschichte eine grosse Rolle und beanspruchen in der Tiergeographie, Planktonforschung und auch in der Hydrogeographie einem ganz hervorragenden Platz. Eine Aenderung der Namen würde eine schwere Schädigung bedeuten.

(1) *Doliolum* Quoy & Gaimard, 1834.—*Doliolum* ist von Otto 1823 (*N. Acta Ac. Leop.*, v. 11, p. 313) für eine wohl durch *Phronima* ausgefressene *Pyrosoma* aufgestellt worden. Dann ist *Doliolum* von Quoy & Gaimard, 1834 (*Voy. Astrolabe*, v. 3, p. 599) gut beschrieben und jetzt in letzterem Sinne allgemein in Gebrauch. Den bisherigen Regeln nach würde *Doliolum* Synonym zu *Pyrosoma* werden, für *Doliolum* in heutigem Sinne würde ein neuer Name gebildet werden müssen. Der Familienname Doliolidae würde verschwinden.

(2) *Pyrosoma* Péron, 1804.—1804 beschreibt Péron (*Ann. Mus.*, Paris, v. 4, p. 440) *Pyrosoma* und ebenfalls 1804 Bory (*Voy. Iles Afr.*, v. 1, p. 107, nota) *Monophora*. Welcher der beiden Namen der ältere ist, lässt sich nicht feststellen, aber aus Quoy & Gaimard, 1834 (*Voy. Uranie & Physicienne*, p. 495) scheint hervorzugehen, dass *Monophora* älter ist; sie schreiben "Bory—avait donné le nom de monophore à un mollusque, qui depuis a été appelé pyrosome Péron." Es empfiehlt sich den Namen *Pyrosoma* für alle Fälle zu sichern.

(3, 4) *Salpa* Forskål, 1775, und *Cyclosalpa* Blainville, 1827.—Diese beiden Genera sind durch Ihle, 1911 (Zool. Anz., v. 38, pp. 585–589) verteidigt und auch in seine Bearbeitung in "Das Tierreich" (v. 37, 1912; Siehe auch Nota p. 27, von F. E. Schulze) übergegangen. Wir glauben uns mit diesem Hinweise¹ begnügen zu können und erlauben uns noch an die gegenteiligen Aufsätze¹ von Poche (Zool. Anz., v. 32, 1907, pp. 106–109; v. 39, 1912, pp. 410–413) zu erinnern.

(5) *Appendicularia* Fol, 1874.—*Appendicularia* wurde von Chamisso & Eisenhardt, 1820 (N. Acta Ac. Leop., v. 10 (11), p. 362, t. 34 f. 4), für eine arctische, nicht erkennbare Art, aufgestellt. Fol hat 1874 (Arch. Zool. exper., v. 3, notes, p. 49) den Gattungsnamen für die tropische Art *Appendicularia sicula*, die von der arctischen sicher generisch verschieden ist, übernommen und darauf hin hat sich der Name in letzterem Sinne allgemein eingebürgert. *Appendicularia* würde anderenfalls eine Species incerta enthalten und für *Appendicularia* mit der Species *sicula* würde ein neuer Gattungsnamen aufzustellen sein. Der Name der Ordnung Appendiculariæ würde verschwinden.

(6) *Fritillaria* Fol, 1874.—Quoy & Gaimard, 1834 (Voy. Astrolabe, v. 4, p. 306) stellen den Namen *Frétiliaires* auf [(*Fritillaria* Huxley (1851, Philos. Trans. (London), part 2, p. 595), *Fritillaire* C. Vogt, 1854 (Mém. Inst. Genève, v. 2, no. 2, p. 74)], identifizierten ihn aber sofort mit *Oikopleura* Mertens, 1831. Um den Namen *Fritillaria* zu retten, hat Fol, 1874 (Arch. exper., v. 3, notes, p. 49) ihn in bestimmten von früherem abweichendem Sinne gebraucht, in welchem er sich vollständig eingebürgert hat. *Fritillaria* würde Synonym zu *Oikopleura* und eine Neubennung nötig.

¹ The secretary spends an average of about six (6) hours per week in studies and correspondence for the Commission on Nomenclature, and he earnestly requests all persons to give full details with full references to every case submitted. Even slight omissions cause a loss of time. The secretary also respectfully requests that authors submit their cases in typewriting, rather than in handwriting.—C. W. S.

C. W. STILES,
Secretary of Commission

SPECIAL ARTICLES

A RUST—NEW ON APPLES, PEARS AND OTHER POME FRUITS¹

FOR several years the writer has been studying an interesting rust on several cultivated and native species of the pome family. In 1908, the æcial stage of this rust was found on the serviceberry (*Amelanchier florida* Lindl.) and on the thornapple or haw (*Cratægus douglasii* Lindl.); later, the same rust was found on apples, pears, quinces and related fruits, as noted below. The rust on *Amelanchier florida* and *Cratægus douglasii* has been referred to *Æcidium blasdaleanum* D. & H., the telial stage, *Gymnosporangium blasdaleanum* (D. & H.) Kern., occurring on the incense cedar (*Libocedrus decurrens* Tor.).

During the past six years the writer has paid particular attention to this rust for the reason that it seems to be of considerable economic importance. While it occurs rather sparingly on practically all varieties of apples so far observed, it has been found to attack certain varieties of pears very seriously. Quinces are also subject to considerable injury by this rust. In 1910, and again in 1912, this rust was so serious in a block of Winter Nelis pears as to practically destroy 95 per cent. of the crop. The fruit was badly deformed and fully 50 per cent. of the leaves were found infected. The fruit and stems in many cases were completely covered with æcia, distortion and dropping of the fruit being the result. All varieties of pears are not equally susceptible, but both European and Oriental varieties were found affected. Oriental hybrids

¹ A preliminary paper.

also showed infection in a more or less serious degree. This rust is not roestelia-like, as in the case of the more common apple rust and other rusts whose telial stage is a Gymnosporangium. The incense cedar which bears the telial stage is very common in southern Oregon, being found on the floor of the Rogue River Valley at an altitude of 1,400 feet. The proximity of incense cedar trees to apple and pear orchards is therefore of considerable economic importance.

The hosts upon which the æcia of this rust have been found are:

Malus malus (L.) Britton (apple).

Malus floribunda Sieb. (several varieties) (flowering crab).

Pyrus communis L. (pear).

Pyrus chinensis (Oriental pear).

Pyrus sitchensis (Roem.) Piper (mountain ash):

Malus diversifolia (Bong.) Roem. (native crab apple).

Cydonia vulgaris (L.) Pers. (quince).

Cydonia japonica (Thumb.) Pers. (Japan quince).

Amelanchier florida Lindl. (serviceberry).

Crataegus douglasii Lindl. (thornapple or haw).

Culture records and final proof will be given in a detailed paper which will be published in the near future. This preliminary paper is given simply as a statement as to what has been found.

PATHOLOGICAL LABORATORY,
MEDFORD, OREGON,
September 1, 1913

A POSSIBLE MUTANT IN THE BELLWORT (*Oakesia sessilifolia*) WHICH PREVENTS SEED FORMATION

The sessile-leaved bellwort (*Oakesia sessilifolia*) is used in many elementary classes in botany as a convenient type to illustrate the Lily family. The normal pistil with a single detached stamen is shown in Fig. 1, magnified three diameters. There are three stigmas terminating styles which are free at their extremities. In class material collected late in the

spring of 1912, flowers were discovered with pistils of the form shown in Fig. 2. The pistil is shorter and thicker than in normal flowers but the essential abnormality consists in the transformation of the three stigmas into func-

FIG. 1.

tional stamens, each with a pair of pollen sacs. Aside from the hermaphroditism of the pistil, the abnormal flowers do not differ in appearance from typical blossoms and bear their full quota of six normal stamens. The stigmatic anthers are well formed and filled with perfect pollen indistinguishable from that produced in typical anthers. In three per cent. grape sugar as well as in cane sugar, pollen from the two

FIG. 2.

types of anthers show an equally high per cent. of germinations. Eleven attempts were made last spring to pollinate normal pistils with pollen from abnormal flowers, pollen both

from stigmatic and from typical anthers being used, but in no case did seed set. Very few capsules were found with seed this last season, however, on untreated plants. In the spring of 1913 search was made for flowers with stigmatic anthers. Of 305 flowers examined from a woodlot which comprised about five acres, there were only 13 with stigmatic anthers. Twelve were found in a patch about 10 ft. square and a single specimen 100 ft. distant. A single flower with stigmatic anthers, however, had been found the previous year about 200 yards from the patch just mentioned. Some few of the flowers classed as normal had rudimentary pistils though normal stamens. One hundred and thirty-two flowers from outside this woodlot were found to be normal. The total number is not sufficient to warrant one in making a suggestion as to the probability of the abnormal form having originated in this single locality.

The transformation of stigmas into anthers seems to completely block the possibility of fertilization, for the ovules which are laid down in deformed pistils have never been found to develop. The abnormality described, therefore, has a double interest. It not only shows an alteration in the products of an organ with a highly stereotyped sexual development, but it also offers an instance apparently of a mutation directly unfavorable to the reproduction of the species. In consequence the subject has seemed worthy of further investigation and the present note is to call attention of botanizers this spring to the possible occurrence of the abnormality in other localities. We should be glad to correspond with any one finding abnormal flowers of the bellworts.

A. F. BLAKESLEE,

A. F. SCHULZE

CONNECTICUT AGRICULTURAL COLLEGE,
STORRS, CONN.

SOCIETIES AND ACADEMIES

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At the 470th regular meeting of the society held December 16, 1913, James Mooney, of the Bureau of American Ethnology, delivered an ad-

dress on "The Gaelic Factor in the World's Population." The speaker dealt chiefly with the Irish Gaels and drew a distinction between the Irish of native Gaelic stock and the unassimilated alien element massed in several of the north-eastern counties as the result of the "Plantations" under James I. and Cromwell. This alien element was of English and Lowland Scotch stock, with a slight Highland Gaelic infusion, Protestant in religion and mostly Unionists in politics, while those of the old native stock were as solidly Catholic and Nationalist. Speaking broadly, in Ireland the Catholics represent the original Gaelic stock; the Episcopalians, those of English stock, and the Presbyterians and Methodists, those of Scotch origin, constituting respectively about 74, 13 and 11 per cent. of the total population. The present Gaelic race of Ireland is a blend of the Gael proper, a Keltic people who arrived in the country probably from northern Spain about 1,000 B.C., and of all other races who preceded or followed them up to the end of the thirteenth century, including the neolithic man, the unknown megalith builders, the dark-haired Firbolg, the Piets, Danes, Normans and Welsh. The Irish immigration to the American colonies previous to the Revolution was mainly of the alien Scotch and English element, known sometimes as Scotch-Irish. The Gaelic Irish immigrants did not begin to arrive in any great number until after the war of 1812, excepting in Maryland.

The wars growing out of the Reformation and the Stuart contests reduced the Irish race from an estimated two and a half million in 1560 to about 960,000 at the end of the Cromwellian war in 1652. In 1845 it reached its maximum estimate of 8,500,000. Then came the great famine of 1846-47. Within three years nearly 1,500,000 perished of hunger or famine fever. This started the great flood of emigration by which Ireland has lost virtually one half its population within sixty years. In 1911 it stood at 4,390,219, the lowest point reached in over a century. Owing to governmental and economic conditions this decrease has been chiefly at the expense of the old native Gaelic stock rather than the Planter stock, the Gaelic percentage, as indicated by the religious statistics, having fallen from 83 to 74. In the sixty years ending March 31, 1911, according to the official British figures, 4,191,552 emigrants left Ireland, or nearly as many persons as are now living in the country. About three million of these came to the United States, the total Irish im-

migration to this country from 1821 to 1900 being, officially, 3,871,253. From 1821 to 1850 the Irish constituted nearly one half of all our immigrants. Previous to the Revolution the "Scotch-Irish" immigration was so great that in an official Parliamentary inquiry in 1778 it was asserted that nearly one half of the American Revolutionary Army was of Irish origin. Since 1870 the number of Irish-born in the United States has steadily decreased, by death and dwindling immigration. According to the census of 1910 there are now in the United States of Irish birth or parentage, 4,504,360. This does not include any of the 811,000 non-French Canadians in the United States, of whom a large proportion are of Irish blood, or any of the 876,000 coming from England, of whom also a large number are of Irish origin. Neither does it include any of the 1,177,000 American born "of mixed foreign parentage," including such parentage combinations as Irish and Germans, which alone probably runs above fifty thousand. Among the states, New York stands first with 1,091,000 of Irish birth or parentage; Massachusetts second, with 633,000, and Pennsylvania third, with 570,000. For all these figures it may be asserted that more than four fifths are of Gaelic stock.

By the latest British census, 1911, the population of Ireland was 4,390,219, of whom all but 157,037 were native born. Of the native born about 74 per cent. or 3,245,000 represent the old Gaelic stock. By the same census there were 375,325 persons of Irish birth then living in England and Wales, while an unofficial estimate puts those in Scotland at about 220,000 or nearly 600,000 for the whole island, which with the children of Irish parentage would probably total at least 1,500,000. The same census gives 139,434 Irish born to Australia, or perhaps 350,000 of Irish blood. South Africa and the other British colonies, exclusive of Canada, have (estimated) 100,000 of the same stock, while Canada has in round numbers 990,000 of Irish birth or parentage, of whom about 750,000 are of Gaelic origin, as indicated by religious denomination. Outside the countries already named, Argentina has some 15,000 Irish born and the rest of Latin America possibly as many more, with perhaps another 15,000 or 20,000 scattered over the rest of the world. To sum up, the total Irish-born population throughout the world is now about 6,875,000, or about 1,625,000 less than the population of the home country alone in 1845, while the whole number of unmixed Irish blood may be about seventeen million, of whom nearly fifteen million are of Gaelic stock. The total

Gaelic population—Irish, Scotch and Manx—of fairly pure stock and racial identity, in every part of the world, probably numbers close to twenty million.

At a special meeting of the society held on January 6, at the National Museum, Dr. Truman Michelson, of the Bureau of American Ethnology, delivered an address, "Notes on the Fox Indians of Iowa." Their own native name is Meskwa'ki'ag', "Red-Earths"; the French name, *les Renards*, is derived from the appellation of a single gens, Wago'ag', "Foxes"; the English name "Foxes" is a translation of the French *les Renards*; the term "Outagamies" (and variants) is derived from the Ojibwa Utagamig, "they of the other shore." Their closest linguistic relations are first with the Sauk, then the Kickapoo, then the Shawnee, and then the so-called Abnaki tribes. They are also comparatively close to the Menominee and Cree as compared with the Ojibwa, Ottawa and Potawatomi. The thesis that the Foxes were once an Iroquoian people and subsequently took up an Algonquian dialect can not be substantiated. There is presumptive evidence that the Foxes were once in the lower Michigan peninsula. However their proper history begins in the last half of the seventeenth century in Wisconsin on the Wolf and Fox rivers. After the famous Black Hawk war, the Sauks and Foxes sold their remaining lands in Iowa and agreed to remove to Kansas. Nevertheless small bands of the Foxes returned continually to Iowa. In 1856 the Iowa legislature passed a bill enabling the Foxes to settle in that state. Accordingly they purchased land with their own money, near Tama, Iowa. From time to time this has been added to till they now own about 3,000 acres. The main body of the Foxes did not leave Kansas till the outbreak of the Civil War. In 1896 the state of Iowa relinquished jurisdiction of the Foxes to the federal government, and at the same time certain claims of the Foxes against the Sauks were adjusted. There are some Foxes enrolled with the Sauks of Kansas and Oklahoma; the present population of those in Iowa is about 356.

At the 471st meeting of the society, held January 20, 1914, at the National Museum, Mr. William H. Babcock spoke on "The North Atlantic Island of Brazil," illustrating his address with lantern slides of early maps. Attention was called to three Brazils, that of South America, the Mount Brazil in Tereira and that of the western Ireland peasantry who still believe in a great land called Brazil or Breasail west of them in the

JA

ocean. This last is probably the original Brazil, from which the others received the name, it being identical with that of a mythical pagan Irish hero and also practically with that of St. Bresal. Outside of Ireland it first appears in the expression "grana de Brasile"—grain of Brazil—in a commercial treaty of Ferrara, Italy, dated 1193, and another Italian document of 1198. The speaker suggested that the primary Brazil, west of Ireland, may have been the region surrounding the Gulf of St. Lawrence. The maps of Dalorto 1325 and Bulcort 1339 were presented as the first showing Brazil, a nearly circular figure west of southern Ireland. The corroborative testimony of the Norse sagas as to Great Ireland and the opinion of Dr. Storm and Dr. Fisher identifying Brazil with Markland are best supported by the Catalan map of 1480. The general argument was that some who spoke Irish reached the St. Lawrence Gulf region at a very early period and gave it the name Brazil.

At a special meeting of the society held February 3 at the National Museum, Miss Frances Densmore, of the Bureau of American Ethnology, read a paper on "Sioux War Songs," using the stereopticon, the phonograph and vocal selections in illustration of her theme. A number of native drawings of war incidents were shown. War among Indians was not an occasional calamity, it more nearly resembled a steady occupation. To the individual it offered a career. A man could best become rich and honored by going to war. A man was rated according to his generosity, and having given away his goods there must be some way of securing a new supply of wealth. A war party afforded this opportunity. War was a means of revenge, was for the defence of the home and was the protection of the hunting ground which meant the food supply. A war party traveled far and brought back strange tales of distant lands. New customs were frequently introduced into the tribe as a result of war expeditions or the taking of captives. Only a successful warrior could belong to the leading societies of the tribe, with their special tents for meeting, their feasts and their parades. But the greatest reward was the right to sing of one's valor at the assemblages of the tribe.

DANIEL FOLKMAR,
Secretary

THE NEW ORLEANS ACADEMY OF SCIENCES

The annual meeting of the Academy was held in Tulane University on Tuesday, March 17, with

President Dr. Isadore Dyer in the chair and a full quorum of fellows and members. The following resolutions were passed upon the death of Dr. Alcee Fortier:

WHEREAS, By the death of Dr. Alcee Fortier the New Orleans Academy of Sciences has lost one of its oldest fellows, one who took an active part in the reorganization of the Academy in 1886, was its corresponding secretary from 1886 to 1890, and published a valuable contribution on Romance Philology in the proceedings of 1888,

Resolved, That we, the fellows and members of the New Orleans Academy of Sciences, do hereby express our sincere appreciation of his most valuable services to this organization, not only in his official capacity as secretary, but also as a scholarly contributor to its proceedings and furthermore our deep sense of the loss which the Academy has sustained by his death.

Resolved furthermore, that a copy of these resolutions be incorporated in the minutes of the Academy and that copies also be sent to his family, to SCIENCE and to the press of this city.

Officers for the ensuing year were elected as follows:

President—W. B. Gregory, professor of experimental engineering, Tulane University.

First Vice-president—Gustav Mann, professor of physiology, Tulane University.

Second Vice-president—W. A. Read, professor of English, Louisiana State University.

Secretary—R. S. Cocks, professor of botany, Tulane University.

Treasurer—Ann Hero, professor of chemistry, Sophie Newcomb Memorial College.

Librarian-Curator—J. H. Clo, professor of physics, Tulane University.

Corresponding Secretary—Pierce Butler, professor of English, Sophie Newcomb Memorial College.

The scientific program consisted of the following papers: (1) "Some Theories of Valence," by H. W. Moseley. The paper traced the development of the doctrine of valence from a historical view-point. Some of the modern theories were then taken up in more detail, especially the theories of Abegg, Spiegel and Arrhenius, Ramsay, Friend, Thompson and Werner. The paper closed with mentioning some recent observations of Bray and others upon valency and tautomerism. The paper was discussed by Dr. P. B. Caldwell. The second paper was by R. S. Cocks calling attention to several interesting facts connected with plant distribution in Louisiana, dealing especially with the eastern portion of the state.

Drew's Invertebrate Zoology

The New (2d) Edition

For this edition Professor Drew has subjected his book to a very searching revision, bringing it into accord with the latest knowledge. His work gives you a working knowledge of comparative anatomy and an appreciation of the adaptation of animals to their environments.

Prof. JOHN M. TYLER, Amherst College: "It covers the ground well, is clear and very compact. The table of definitions is excellent."

Invertebrate Zoology. By Gilman A. Drew, Ph.D., Assistant Director of the Marine Biological Laboratory, Woods Hole, Mass. 12mo of 213 pages. Cloth, \$1.25 net.

Daugherty's Economic Zoology

This work is issued, for convenience, in two parts. Part I is a *Field and Laboratory Guide*, interleaved for notes. Part II is the textbook part or the *Principles*. The *life and habits* are emphasized.

J. REMSEN BISHOP, Ph.D., Eastern High School, Detroit. "The illustrations alone prove the book superior to any other."

By L. S. Daugherty, M.S., Ph.D., Professor of Science, Missouri Wesleyan College; and M. C. Daugherty. Part I—*Field and Laboratory Guide*. 12mo of 275 pages, interleaved. Cloth, \$1.25 net. Part II—*Principles*. 12mo of 406 pages, illustrated. Cloth, \$2.00 net.

McFarland's Biology

New (2d) Edition

This work has chapters on the origin of life and its manifestations, the cell and cell division, reproduction, ontogenesis, conformity to type, divergence, structural and blood relationship, parasitism, mutilation and regeneration, grafting, senescence, etc.

Prof. W. R. McCONNELL, Pennsylvania State College: "It has some admirable features, the most valuable of which is the careful resume of the subjects of heredity and evolution."

Biology, General and Medical. By Joseph McFarland, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College, Philadelphia. 12mo of 457 pages, illustrated. Cloth, \$1.75 net.

Stiles' Nutritional Physiology

Dr. Stiles takes up each organ, each secretion concerned with the process of digestion, discussing the part each plays in the physiology of nutrition. A valuable feature is Dr. Stiles' happy use of homely similes.

Prof. COLIN C. STEWART, Dartmouth College: "It is remarkable for the fineness of its diction and for its clear presentation of the subject."

Nutritional Physiology. By Percy G. Stiles, Assistant Professor of Physiology in Simmons College, Boston. 12mo of 271 pages, illustrated. Cloth, \$1.25 net.

THE STUDY OF HUMAN BEHAVIOR¹

My part in this symposium must be that of the comparative psychologist who, while professionally engaged in the experimental study of the behavior of lower organisms, is keenly interested in human behavior and in the development of methods by which it may be profitably studied. I propose, in this discussion, to try to bring some of the experiences of the student of the behavior of animals to bear upon the problems which the eugenic investigator meets. Especially I shall attempt to indicate the necessity for an analytic procedure on the basis of carefully wrought out methods of experimental control and observation, and the thorough-going study of the components of human responses to situations rather than of complexes such as are actually presented to us in the behavior of human beings.

Human behavior is only a part, albeit a most important part, of the materials of the general science of organic behavior. It presents essentially the same kinds of problems as does the behavior of any other mammal; and it must be studied by methods similar to, if not actually identical with, those employed by the student of infra-human behavior. I should be in-

¹ The substance of the writer's contribution to a symposium on the Study of Human Behavior at the Conference on Eugenics, held at Cold Spring Harbor, Long Island, June 19 and 20, 1913. Being Contributions from the Psychopathic Hospital, Boston, Massachusetts, No. 25 (1913. 25): previous Contribution, P. H. Contributions 1913. 24, was Robert M. Yerkes: "Comparative Psychology: A Question of Definitions." *The Journal of Philosophy, Psychology and Scientific Methods*, October 9, 1913.

clined to go still further in maintaining that a student of comparative psychology, or the behaviorist in the wide sense, is admirably fitted, by his experience in dealing with varied forms of behavior, by his knowledge of the genetic relations or developmental history of organic behavior, and by the ingenuity in devising and using experimental methods which his work forces him to acquire, to formulate problems in human behavior and to suggest methods of solving them.

There are at least three valuable points of view from which the behavior of man may be studied: the psychological; the physiological; and the pragmatological.² The first inclines the observer to an analytic study of activity in its relations to the ideas, motives, purposes and ideals of the organism; in a word, to a study whose goal is the description of behavior as an expression of will. The second disposes the investigator to seek definite knowledge of the functions of motor organs and of the relations of those mechanisms to other bodily organs and processes. From this point of view, the organism is studied as a living thing, influenced by environment and reacting upon it. The third directs him to the products of organic activity, as keys to the meaning of conscious behavior. It may reasonably be maintained that the understanding of the behavior of any organism, and most of all that of man, is conditioned by reliable and reasonably complete knowledge of the experiences of the organism, of its life processes, including its complex as well as its simple forms of behavior, and of the products or results of its bodily activ-

ities. We may consider fortunate those students of human behavior who are able to take, in turn, as occasion demands or as opportunity makes possible, these three points of view, for we must recognize that man is a self-conscious being who exhibits varied and complex activities and at the same time produces works of science, industry and art which are of deep psychological significance. This, however, is merely equivalent to the statement that human behavior may be clearly understood only if viewed in its relations, on the one hand, to its structural conditions, and on the other, to its purposes and results.

The history of science indicates that man has been surprisingly slow to come into close quarters, in a strictly scientific manner, with his own behavior. Of psychological, neurological, ethnological and archeological facts we to-day have an abundance. But we know relatively little concerning the facts and laws of human activity. This is true, I believe, chiefly for two reasons. First, because consciousness, presenting as it does a perennially puzzling problem in its relations to body, has absorbed attention; and, second, because the results of human behavior have proved more engaging to most observers, even to most scientific observers, than the behavior itself. To-day, a change is evident, for here and there "human behavior" has become an object of scientific interest. Sometimes this interest is inspired by practical problems; sometimes, by the desire for scientific knowledge. Recently, there have appeared several books³ which, although dealing with

² We lack a term to designate the point of view of the scientific student of the results or products of activity, such, for example, as the abodes of animals or of man, works of art, scientific inventions, etc. I have designated this point of view as pragmatological, in the absence of a more suitable term.

³ Among these may be mentioned "The Science of Human Behavior: Biological and Psychological Foundations," by Maurice Parmelee, New York, 1913; "The Fundamental Laws of Human Behavior; lectures on the foundations of any mental or social science," by Max Meyer, Boston, 1911; "Introduction to Social Psychology," by William McDougall, London, 1908.

the general subject of man's behavior, are indicative rather of the realization of the need of knowledge than of the existence of such knowledge. Without exception, such general discussions as the writer is familiar with display our ignorance of the facts of behavior and of the principles underlying them and serve rather as arguments in favor of the systematic study of this group of phenomena than as satisfactory treatises.

The behaviorist, whether he be physiologist or psychologist at heart, seeks, first of all, accurate knowledge of the facts of behavior. His task it is to analyze behavior-complexes, to discover their conditions or causes, to formulate the laws of their appearance, and to point the way to their control. It matters not to him whether his subject happens to be a horse, an ape, or a man. He adapts his methods of investigation to the problem and the subject in hand and proceeds to gather data. It is characteristic of the recent experimental work in behavior that reactions to simple or complex situations should be broken up into smaller and smaller part processes, and the characteristics of these processes as well as their relations, studied minutely, persistently, accurately.

Our time-honored classification of activities as reflex, instinctive, impulsive, habitual, voluntary, is no longer in favor. Indeed, the speculative discussion of the characteristics of different types of activity and attempts to formulate definitions which shall render these types mutually exclusive have to-day given place to systematic searching for the characteristics or attributes of acts and groups of acts, and for genetic descriptions thereof. Only recently, it must be confessed, have we fully realized that an instinctive act is something to be observed and reobserved under varied and rigidly controlled conditions; something to be studied in its origin and development;

something to be created, if possible, by the control of conditions of organic behavior, rather than something merely to be talked about or defined in abstract terms. The older literature of instinct is vague, general, speculative. The newer is definite, concrete, observational. And what is true of our studies of instinct is true, likewise, of our studies of the various senses and of habits.

It is rather late in this discussion to define behavior, yet an attempt to do so may serve to correct certain misimpressions which seem not uncommon. The term, as used by the scientist to-day, is inclusive not merely of those gross and obvious activities exhibited by man in common with the other animals, but of hidden organic processes. The behaviorist is interested quite as much in reflexes, which might ordinarily be relegated to physiology, as in habitual, or instinctive, or voluntary acts. But he is interested, also, as much in the complex forms of behavior, known as conduct, as in the simpler expressions of human intelligence. Indeed, even the most complex moral and religious forms of activity are regarded by him as material for scientific study.

A strictly scientific study of the varieties of human behavior demands, first, the formulation of problems, for advance comes slowly and uncertainly unless the investigator can definitely formulate his task. It demands, further, thorough knowledge of the methods of physiology, of psychology, of physics, and of chemistry, and ingenuity on the part of the experimenter in adapting these methods to his immediate needs. Finally, it demands familiarity with the facts of behavior in other organisms, in order that the comparative method may be made to lend abundant aid.

Noteworthy changes have occurred in the study of behavior during the past twenty

years. Then, observation was naturalistic, general: now, it is experimental, specific. Most obvious and most important of the changes is the development of methods by which the conditions of observation may be controlled and the results precisely recorded. The older work was, on the whole, crude, inconclusive, wasteful of time, leading to few safe generalizations; the newer, by contrast, is precise, carefully controlled, and tending to lead to the formulation of laws. It is, of course, desirable that we recognize that not all observation can be conducted under experimental conditions, that the naturalistic method in the study of human behavior as also in the study of animal behavior has its proper and important place. We should gladly recognize its values, while insisting upon the importance of supplementing it by the experimental study of the same phenomena.

But the practical-minded person has doubtless been asking, throughout this introductory discussion, of our topic, "How may the reactions of a person be scientifically studied? Is it possible, ordinarily, to subject a human being to such conditions of observation as are used in experiments with other animals?" A few examples from studies of human and infra-human behavior will serve as an answer to these questions.

One of the most interesting aspects of organic activity is its modifiability. We designate this as habit-formation. Now, it happens that in a great variety of organisms the formation of habits has been studied experimentally. In the case of the dancing mouse,⁴ for example, I investigated the relation of rapidity of habit-formation to certain external conditions. With an

apparatus so arranged that the mouse could choose as its route through the experiment box either a dark or a light passageway, I determined the number of experiences necessary in order that the animal should learn that, no matter what the spacial relations of the passageways, only the light one could safely be chosen as a way of egress, since each time the dark passageway was entered a disagreeable electric shock resulted. It was the problem of the observer to discover how quickly, under a given set of conditions, the mouse would learn always to avoid the one passageway and to seek the other. In this experiment, which was so conducted that strictly comparable results were obtained from several individuals, it was first ascertained that the less the difference in lightness of the two passageways, the longer it took the mouse to learn to choose correctly. Next, it was determined that the rapidity of learning varied with the strength of the electric shock, which was regularly given as punishment for mistakes. When the passageways differed markedly (discrimination easy), the stronger the shock the more rapid the learning. When the passageways differed slightly (discrimination difficult), beyond a certain point, increase in the strength of the shock delayed the learning process. When the passageways differed by an intermediate amount, it appeared that an intermediate strength of stimulus was most favorable to habit-formation. From these observations, it was possible to deduce the following law for the behavior of the dancing mouse: As the difficultness of visual discrimination increases, that strength of electric stimulus which is most favorable as a condition for the acquisition of a habit tends to approach the threshold.

In this investigation, we have, first, a definite problem; second, a reasonably large number of observational data (facts of be-

⁴ Yerkes, Robert M. and Dodson, John D., "The Relation of Strength of Stimulus to Rapidity of Habit-formation," *Journal of Comparative Neurology and Psychology*, 1908, Vol. 18, p. 459.

havior), and, third, a law of behavior for the particular organism in question. In effect, what I did with the dancing mouse might be done with human subjects, should it seem desirable to gain definite knowledge of this aspect of habit-formation. As it happens, precisely the kind of knowledge of human behavior which such experimental methods yield is necessary, if we are ever to have a thoroughgoing science of human behavior which will enable us to deal with our fellows effectively.

Another illustration may be taken from the study of imitative activity. It is generally recognized that imitation may be studied experimentally in any organism. But up to the present most observations of this group of phenomena have been casual, and our opinions concerning the importance of imitation in any organism are quite likely to be based upon insufficient or inaccurate information. With sparrows, canaries, mice, rats, cats, dogs, monkeys, experiments have been made to determine the nature and extent of imitative reaction, and there is no obvious reason why the methods of the behaviorists should not be adapted to the study of the imitative tendency in human beings.

In order to exhibit, in its general features, a method of studying imitation experimentally, we shall consider investigations of this aspect of behavior in monkeys.⁵ The observer, first of all, seeks for a number of acts or series of acts which his animals either can not learn to perform of their own initiative or learn with extreme difficulty. Such acts are most readily discovered in connection with artificially arranged situations, as, for example, in

connection with puzzle or problem boxes and similar experimental devices. He then teaches one animal to perform an act and thereafter, under definitely describable and constant conditions, he permits another animal to observe the behavior of the first. Any tendency for the second animal to imitate the first, or to modify its behavior in accordance with the activities of the first, is noted. Thus, by repetition after repetition of this sort of experiment, the observer strives to get definite knowledge of the nature and extent to which the behavior of one animal influences that of its fellows. It is, of course, necessary in such an experiment to work out a method carefully and to make all observations under carefully controlled conditions. It is necessary, also, to measure as precisely as possible several aspects of the behavior of the observing individual, and thus to depend not upon general impressions, but upon records which can not be influenced by any bias on the part of the experimenter.

Such experimental studies as those of Watson and Haggerty have proved that certain monkeys imitate much less generally than is commonly supposed. And further, that they imitate seldom, if ever, in the purposive manner in which man imitates. It seems that although they influence one another markedly in their behavior, this influence is chiefly a matter of the directing of attention. The imitation of means or of ends in a voluntary and wholly conscious manner rarely appears among the mammals below man.

An illustration from actual experimental work which clearly indicates the need of analyzing behavior complexes and of dealing quantitatively with simple bits of behavior is furnished by some recent work which the writer has done with rats. It was his task to try to discover the modes of heredity of savageness and wildness in rats.

⁵ Haggerty, M. E., "Imitation in Monkeys," *Journal of Comparative Neurology and Psychology*, 1909, Vol. 19, p. 337; Watson, B., "Imitation in Monkeys," *Psychological Bulletin*, 1908, Vol. 5, p. 169.

In order to accomplish this task, it was necessary to analyze savageness and wildness. This meant discovering those acts or organic processes which, taken together, mean to the observer savageness or wildness. The first result of observation was that biting, squealing, struggling to escape, or attacking the experimenter, and process of excretion, appeared as important elements of savageness. The experimenter, relying upon these elements, measured, roughly, the savageness of a large number of individuals, arranging them according to their behavior in six grades, designated 0 to 5. On the basis of this obviously crude preliminary work, certain facts indicative of the mode of transmission of savageness and wildness were ascertained.⁶

In yet other observations on rats which involved the comparison of two groups, stock individuals and closely inbred individuals, it appeared that the behavior of the two groups, in the face of certain experimentally arranged situations, differed greatly. This, upon careful observation, the experimenter was able to attribute to differences in temperament. The stock rats were rather active, energetic, quick moving, whereas the inbred animals were more stolid, slow and deliberate. In order that the reactions of these individuals in various experimental situations be properly interpreted, it is essential that the experimenter obtain knowledge of their temperamental character, such, for example, as degree of nervousness or of timidity, of savageness or wildness, quickness of response, persistence, energy and so on through the list of aspects of behavior which, looked at as a whole, might be considered the temperament of the animal. The point which I am trying to emphasize is this. If we are to work effect-

ively, with human beings or other animals, we must analyze the concrete behavior of the organism's every-day life into simpler processes and then study these processes, one by one, by means of methods which shall enable us to measure them fairly accurately and describe them with corresponding accuracy and precision.

The application of these observations in the work of the eugenics investigator are obvious, for the latter, in dealing with human behavior, first of all observes complexes. If he is content to continue to observe these complexes and to try to study their behavior in heredity, he may or may not obtain scientifically valuable results. But in any event, his safer course by far is to deal with part processes, first to analyze his complexes and then to select what seem to be the most important elements and carefully study their characteristics and their behavior as possible inheritances. From his own experience, the writer is inclined to urge that it is always safer to deal with items of behavior than to attempt to deal with behavior in a large or wholesale manner—safer, for example, to study capacity for a particular sort of musical expression, singing or violin playing, than to study musical ability in general.

Were we to present more examples from actual work, we might describe methods of studying distance orientation, visual discrimination, other aspects of habit-formation, the permanency of habits, instinct and emotion, in animals, but it will suffice for our present purposes to describe briefly two methods of analyzing behavior which have recently been devised. These methods, unlike those in general use by students of animal behavior, are applicable alike to man and to other mammals, even to birds as well. They were, indeed, planned with the idea that they should make possible the comparison of reaction-types or reactive

⁶ Yerkes, Robert M., "Heredity of Savageness and Wildness in Rats," *Journal of Animal Behavior*, 1913, Vol. 3, p. 286.

tendencies in birds and mammals, and all these in turn with the tendencies displayed by human beings, either mature or immature, either normal or abnormal.

The two methods referred to are the quadruple choice method of Hamilton⁷ and the multiple choice method of Yerkes. The Hamilton method places the subject in an experimental situation which may be reacted to in many different ways and with varying degrees of satisfactoriness or adequacy. The subject of the experiment is placed in a small room on one side of which there are four doors. From experience, he learns that he may escape by one of the doors, and only one, but which of the four to choose is his problem, for it is the plan of the experimenter to lock, in a given trial, the door through which the animal escaped in the previous trial and two others. Any one, then, of three doors may be unlocked in a given trial. The animal has absolutely no way of predicting which is unlocked. The general question is, then, how will a given type of organism or a given individual meet this situation? What habitual manner of meeting it will be acquired? How will the modes of reaction displayed by a child compare with those of an adult; of an ape, with those of a man?

The Yerkes method is similar in purpose to that of Hamilton, but it offers, in the opinion of the writer, somewhat more satisfactory opportunity to evaluate and compare results. It consists, essentially, in the presentation to the subject—bird or mammal; young or old, normal or abnormal—of a bank of twelve keys numbered from left to right, one to twelve. The subject is given to understand, verbally, or through actual experience with the apparatus, that pressing some one of the twelve keys will

yield a certain desired result, such, for example, as the displaying of a picture, the presentation of food, the ringing of a bell. Success in the experiment means, simply, pressing the key which brings the desired result. The experimenter sees to it that in no two successive trials is the same key the one to be operated. He is, further, able to push back out of sight any number of keys and thus to present to the subject as few as one or as many as twelve.

Let us assume that in a given experiment the observer decides that the key the fourth from the left shall always be the "right" one. It then becomes the task of the subject of the experiment to suit his reactions to the number chosen by the experimenter. Only if he discovers the guiding idea of the experimenter can he succeed, trial after trial, in touching the right key at first. This method may be varied almost indefinitely in difficulty, and it may be made to elicit numerous reactive tendencies.

It is obvious that both of the methods thus briefly described above are attempts to elicit general reactive tendencies rather than to analyze reactions minutely and carefully. The methods are indeed intended to bring into clear light those modes of responding to a given situation which are characteristic of different types or conditions of living beings, and thus to furnish a basis for a profitable comparison of reactive tendencies.

I can not conclude this discussion without referring for a moment to a question which is frequently asked and which surely must have been in the minds of some of my hearers; namely, why is it that the behaviorist deals so often with the activities of the lower animals and so seldom with those of man? The question is pertinent, and the reasons, as I see them, are significant. They are chiefly two: in the first place, most lower animals are easily obtained,

⁷ Hamilton, G. V., "A Study of Trial and Error Reactions in Mammals," *Journal of Animal Behavior*, 1911, Vol. 1, p. 33.

kept in confinement, bred and reared for experimental purposes; in the second place, many of them, in comparison with human beings, can be readily controlled throughout their lives and subjected to experimental conditions, in definite and measurable ways. Because, then, of the availability and controllability of lower animals, it is far easier and more satisfactory to make preliminary, exploratory and problems defining observations on their behavior rather than on that of man. It is further to be considered that the time of a human subject is worth infinitely more than that of an infra-human subject. On the whole, it seems clear that we work to advantage in the early stages of our science of behavior by letting the lower animals help us to the formulation of our problems and the development of our methods. Once fairly oriented and reasonably skilled in our technique, we may, with better effect, attack the problems of human behavior.

The above considerations lead to yet a further reflection concerning the relation of the study of the behavior of infra-human organisms to that of man. To the writer, it seems of preeminent importance that we prepare for rapid advance in our knowledge of human behavior by the systematic, thoroughgoing study of the behavior of some one or more of the anthropoid apes and of the higher monkeys. These creatures are nearest of kin to man, alike in structure and in behavior, and it is quite as surprising as it is unfortunate that we should know so little definitely concerning their mental characteristics or the facts and laws of their behavior. It may fairly be urged, I think, that no task comparable in importance with that of the systematic study of the instincts and intelligence of the apes lies before the behaviorist. Because of this strong conviction, I wish to present the following plan, which is quite

as much in the interest of a study of man's behavior as of that of the anthropoid apes themselves.

It is proposed that a permanent station be established in some tropical country (Borneo and Jamaica would seem well worth considering) where, under favorable conditions, certain of the apes can be bred, reared and observed. Year after year, the staff of such a station should conduct systematic experiments with these animals and record observations of their behavior in their semi-wild state. There should be equally good opportunities for naturalistic and for experimental work, for the study of the development of forms of behavior, and of the relations of particular acts to definite environmental or other conditions. The value of such work would depend largely upon its continuance over a long period of time and upon the possibilities of breeding the animals and of observing the development of activities. To any one interested in the study of behavior, an elaborate program of research will at once present itself. It is wholly unnecessary, at this time, to enter into the details of such a plan. Suffice it to say that several biologists and psychologists, who have been consulted concerning it, enthusiastically approve of the proposal and earnestly hope that such a station may be established.

This plea for special and unique facilities for the systematic study of the apes is presented to you because upon students of genetics, eugenic investigators, and sociologists, quite as heavily as upon behaviorists and psychologists, must rest the responsibility of carrying out any such proposal. Moreover, I can urge the plan upon your consideration with enthusiasm because I fully believe that this apparently roundabout way to knowledge of the laws of our own behavior is in reality the most direct and desirable way. Certain it is that if

we neglect our present opportunities to study the anthropoids, our children's children will condemn us for neglecting invaluable opportunities. To-day, the chimpanzee, the orang-outang, the gibbon, as well as many species of monkey, are at hand for observation. A generation or two hence, many of the primates may be extinct. Should we not, in the interests of genetics, whether we be concerned primarily with problems of structure or of function, see to it that we adequately use, for the purpose of advancing human welfare, our present primate materials?

ROBERT M. YERKES

HARVARD UNIVERSITY

SWEATING THE SCIENTIST¹

In the four last numbers of *Science Progress* a notice has been inserted asking for information on the emoluments of scientific workers; and a considerable number of interesting replies have been received. They are not numerous enough to form a basis for any statistical investigation of the subject—which it is hoped may be attempted later on when more evidence has been collected; but the replies received, combined with information which may be otherwise obtained, suffice to prove the low scale of payment given throughout the British Empire for such work.

The term "scientific worker" includes, according to the notice, all salaried workers—that is, men of all grades, namely, research students, assistants, professors, directors of laboratories, and other fully paid workers, and also half-time and whole-time workers. The duties generally include teaching and the administrative charge of university departments, museums and special laboratories. The lowest scale of pay mentioned in the replies is £85 a year for half-time work; but it is notorious that a large number of such workers, espe-

cially in medical subjects, are paid nothing at all. The pay of junior posts (which are also sometimes unpaid) rises from about £120 to £200, £250 and, rarely, £300 a year. These are of course not so important as the upper scales of pay for full-time professorships and permanent appointments. For the latter, the highest pay mentioned in the replies amounts to £850 a year, with a small pension (Ceylon). The next highest are salaries of £750, both in South Africa, and one of £500 in Canada, with small pensions generally contributed to by the holders of the appointments. It is well known that many professorships in Britain yield £600 a year, with very small contributory pensions. In no cases do there appear to be any arrangements for family pensions in the event of the holders' death—such as are often provided in the public services; nor insurance against illness or accident. Notoriously, very few even of the highest posts receive a salary touching or exceeding £1,000 a year; and in nearly all cases the pensions are contributory and are of a very small amount—retirement being often compulsory at the age of 60 or 65 years. Progressive rises of pay are also seldom provided for; so that a man who obtains an appointment when comparatively young can seldom hope for any increase during the rest of his life. Lastly, payment is laid down at many universities according to a flat rate, or according to fixed endowments which depend upon the funds originally allotted—so that no provision is made for retaining specially good men. In some cases holders of fully paid appointments are able to increase their emoluments by outside work. Many medical professorships are quite unpaid.

The rates of pay must be judged by the locality in which they are given. Thus £750 in South Africa is worth very much less than that sum in Britain, the cost of living being perhaps twice as great. A correspondent from Canada remarks that a salary of £800 a year in England is equivalent only to about £600 a year there, and is not sufficient for a professor. "A member of a learned community," he says, "can not live in a back street like a laborer, and if he takes an unfurnished house

¹ An editorial article printed in the April number of *Science Progress in the Twentieth Century: A Quarterly Journal of Scientific Work and Thought*, edited by Sir Ronald Ross.

in a good locality here the rent will be about a quarter of his income. . . . The smallness of income results, in my case, in my being unable to buy books, subscribe to scientific journals, or join all the learned societies I ought, or to travel to see other universities." Similar complaints are made from elsewhere; and the conditions in Britain are notorious.

Of course, very junior posts are generally financed by scholarships; and are naturally not highly paid because the holders are young men who are, practically, being apprenticed to their labors. The senior posts are those which must be considered in drawing any comparison between the payment for scientific work and other lines of effort; and even in this respect other conditions besides the payment must be taken into account. On the whole, however, such comparison leads to a very unfavorable conclusion regarding the present payment of scientific workers in Britain. It is bad, compared even with the Church. In middle posts, the salaries may be slightly higher; but in academical life the incumbents are obliged to live in towns and are rarely provided with housing. The highest appointments open in science certainly seem to be paid much less than the highest appointments in the Anglican Church—though the latter figures can not be very easily ascertained; and, at least, no scientific men have a seat in the House of Lords by virtue of their office or work. The highest salaries for scientific work are very much less than those given in the Army and Navy—which reach to £4,000 or £5,000 a year, and probably more when certain allowances are added. The scientific and academical sides of the medical profession show a similar state of affairs when compared with the clinical side—the incomes of the former seldom if ever exceeding £1,000 a year, while those of the latter are well known to run to many times that amount, especially in surgery. Compared with the law, science stands nowhere at all in Britain, either in payment or in position. The disparity is still greater in comparison with "business"; and the enormous fortunes made in innumerable directions by manufacturers, shipowners, retail and wholesale traders, vend-

ors of registered articles, financiers, and so on, would in many single cases cover the whole funds allotted to science throughout the great British Empire. Even certain branches of art, such as the drama, singing and acting, have a large advantage compared with scientific work.

It is in no grudging spirit that men of science will draw such comparisons. That good pay should be given for good work is an elementary principle governing all lines of effort; but another principle must be held in view—that, if possible, payment should bear some proportion to the value of the kind of work done. We pay an architect or a general more than we pay the bricklayer or the soldier, because the labors of the former are the more important; and the same principle should carry weight in comparisons of the emoluments of the several professions. In the two previous numbers of *Science Progress*, a survey of the value of scientific work to the world has been attempted. It is probably of greater advantage to the world than any other line of effort. Science has become our premier industry, and governs every other industry just as the work of the architect governs that of the individual bricklayers. The world receives not only "fairy tales" from science, but also the most wonderful fairy gifts—a greater knowledge of the universe in which we live, a greater power over nature and over barbarism, greater precision in invention, in the treatment and prevention of disease, and in our manner of judging regarding all matters under discussion. Can it be truly said that the labors of any other professions are so valuable to mankind? Where the priest, the clinician, and the lawyer do good service to the few people surrounding them, and the soldier, sailor and politician do good service for their country, the discoverer confers benefits upon the whole world, and not for the present generation only, but for all times. We have already argued the case. Mathematics, chemistry, physics, physiology and pathology have practically built up all those great and wonderful additions which modern civilization has added to the civilization of the past, and,

with their sisters of the arts, have made a fitting palace for what ought to be a higher race. Yet the payment of the highly qualified men of the same age who were not so unwise and who are still perfecting them is less than that given to all the other professions, and, compared with the value of the work, is almost infinitely less. Indeed it would appear that the second principle enunciated above is just the opposite of the truth—that work is paid for in the inverse ratio of its value: and this is not a mere cynical gibe, but the actual truth. The greatest benefits which the world has ever received, that is, those which it has received from science, literature, art and invention, have generally been paid for not at all.

But it may now be said that the scale of payment for science is purely a question of supply and demand. That is so—and the same principle governs the case of sweated industries of all kinds. In the latter, the employer exploits the necessities of a crowded and poor population in order to have his work done at the cheapest rate. As regards science, however, the employer is the public itself, and the sweated laborer is the highest type of intellect in the country. The process by which the sweating is rendered possible is something as follows: Young graduates, fired with enthusiasm for science or with the desire of investigating some question which has occurred to them, take scholarships or poorly paid research-studentships. At first, while they are young, everything goes well with them; but after some years they find that the shoe begins to pinch. Then, unfortunately, it is too late. They have lost the time which they should have used in perfecting themselves for their proper profession, whatever that may be—in which they have already been outpaced by men who formed these sciences in the past or so high-minded as themselves. The opening which they may have taken five years previously is now closed to them; and they are compelled to spend the rest of their life under the paralyzing influences described above. This also is the actual fact; and it must evidently produce a disastrous influence,

not only on the men who suffer, but also upon the great studies to which they devote themselves. The most capable graduates are already beginning to perceive the truth and to avoid the toils. The elder men, seeing that investigation leads to nothing, tend to interest themselves only in teaching, compilation of text-books, and attendance upon committees. The enthusiasm and concentration which when found together are called genius become impossible; and we look almost in vain for that high devotion to science which is the only quality she rewards with success. And the punishment does not really fall so heavily upon the worker himself—his enthusiasm for science may quite possibly compensate him for such troubles as those mentioned above. But the punishment falls upon his family; it falls upon the institution which employs him; it falls upon the nation which allows such a thing; and it falls upon science herself.

Besides the low rate of pay given, there are, in this country at least, many small abuses attached to high intellectual work. Even such funds as may be allotted are not used to the best advantage. Large portions of the income of many institutions are given to the maintenance of more or less useless pursuits—which were useful pursuits in the past, but no longer serve the world, or indeed serve it only in a negative sense. Originality and success in research do not receive their due place in selection for appointments. The best paid posts are seldom given for the best work done, but rather for qualities which are of little account—popularity, eloquence, text-book knowledge, private influence, and skill in the arts of time-service. For obvious reasons it is impossible to cite examples, but the fact remains. Of the few Britons of to-day who have done world-service, how many hold the leading public posts even in their own domain? We appear to judge men, not by the work which they have done, but by the work which we may imagine, from their appearance, that they may do if we give them an opportunity. How many of our most distinguished writers, for example, have received academic posts for teaching their own art? And how many of our most

distinguished men of science are now heads of British universities?

Many other disabilities are frequently complained of and resented by scientific workers. The whole system of filling appointments requires careful reconsideration. Some years ago an excellent article on the subject of advertising vacant appointments appeared in the *University Review*. The advertisements are often issued when the post has already been practically allotted—simply as a kind of show to prove impartiality on the part of the advertising body. The result is that numbers of candidates are tempted to put themselves to great trouble and some expense, and are kept upon the tenterhooks of doubt for months. Another abuse, still allowed for academical and hospital posts, is the necessity of canvassing for appointments—a very objectionable system which compels the unfortunate applicant to visit a number of persons with whom he is not acquainted and who often have no knowledge of his subject, and to parade his virtues before them in competition with other unfortunates who are in the same case. We heard some time ago of a distinguished mathematician who was obliged to sue humbly for a poorly-paid post before two local tradespeople—and who was not accepted. Can anything show more clearly than such a state of affairs the low position held by high work in Britain? Indeed the whole system so frequently adopted here of allowing scientific institutions, hospitals and even universities, to be governed by committees of persons of whom many have no qualifications for the work, who are often not even moderately distinguished in any line, but who find their profit in the position, is thoroughly discreditable; and recent disputes in the management of certain hospitals have illustrated the defect.

We have recently started the habit of giving our rare professorships to foreigners—not really because the foreigners are the best men for the posts, but because the institution concerned likes to obtain a reputation for magnanimity. Yet foreign nations are not so generous to us. As a matter of fact we buy, not in the cheapest market, but in the dearest one;

and do so, not from motives of business, but merely out of ostentation. The same indifference to work done is often manifested in the honors given by many learned bodies. We see the academic laurel placed upon the brows of soldiers, sailors and politicians—men who have perhaps done great service in their own line, though not in the line for which such honors should be reserved. The case can of course be argued—as all bad cases can; but it is really a matter of clean taste. Academic honors are meant to promote great world-service; and it is a sign of national degeneracy when they are given for anything lower. One would think that our universities would lead the way in this respect, but it is not so. Some years ago a distinguished colonial premier refused an academic honor on these grounds, and attained great honor by doing so. Few are the struggling workers or the struggling causes which have benefited by the powers in the hands of the great learned bodies. To add grist to their own mill by subservieny to popular idols appears too often to be their chief desire; and where a great worker is honored by them, he is generally a foreigner. A still lower stage, however, has already been reached—where a learned body decorates itself!

We may now ask, what exactly does the British Empire do, as a state, for science, or indeed for any of the higher forms of intellectual effort? Parliament allots £4,000 a year to one learned society, and another £1,000 a year for publications—a magnificent endowment! It allows also occasional small grants to other institutions; and all these are doled out for the expenses of special researches. The larger grants which it gives to universities are devoted chiefly to teaching—a very small proportion ever being really available for investigation. Very little of the money goes to the workers themselves, either to increase their pay or to reward them for services rendered; and the state seems to think that if it provides their test tubes and microscopes it has done enough. In many countries the government wisely pays members of certain academies; but in Britain, not only is this not done, but the state actually exacts gratuitous

services from such members. For example, a government department wishes for expert advice on some matter—it ought to form a commission of its own and honestly pay the expert members of it. Instead of doing this the government department goes to some learned society and asks it to advise on the scientific question at issue. The society is honored by the request, and obtains the advice gratis from its own members. Thus the government gets what it requires for nothing; the learned body is overpowered with the honor rendered to it; and the unfortunate worker is the loser. Such action is very common; unpaid government committees are now becoming the rule, and even reimbursement of traveling expenses is often boggled at. We heard the other day of a man who was actually found fault with for not attending a committee of this nature for which he was not paid. In other words, the state exploits the man of science on account of his enthusiasm for his work and his patriotism. The thing might be excused if the state were to give large funds for scientific work, but as it does not do so such action is extraordinary in its meanness and impropriety.

Many similar points may be cited. The board of education expends annually an enormous sum, amounting to nearly twenty millions a year, on low-class education; but what does it do for the greatest of educators—science, literature, art, drama, exploration, discovery, invention? As was pointed out in the last issue of *Science Progress*, the patent acts do not cover those whom they should most carefully protect, namely the men upon whose investigations nearly all inventions are founded. Quite recently the House of Commons has given itself payment amounting to over a quarter of a million pounds a year. Perhaps this is quite right; but may we not ask whether a small fraction of the money, properly devoted to scientific investigation in many lines, would not be of much greater benefit to the people than are the wranglings of party politicians over questions which will never be honestly decided because they are never honestly considered? Still more recently the state has given, very wisely, £57,000

a year out of the insurance fund for medical researches. It was suggested at the committee which organized the management of this expenditure that a large prize should be available out of the fund for important discoveries; but the money actually offered has now been reduced to a maximum of £1,000. In other words, if a private medical man were to discover the means of prevention or cure of tuberculosis or cancer—which he would not be likely to do without spending years of study over the theme, and probably losing his practice in consequence of his work—his only reward would be £1,000! The discoverer will not be paid; and yet the country hopes to have discoveries achieved! And this brings us to what is really the crowning defect of the national attitude towards high effort of such kinds, namely, that it makes no attempt whatever to pay for any benefits, however great, which it receives from individuals. A successful soldier may indeed receive a handsome donation, and many politicians obtain large pensions; but the highest services in the domains of science, literature and art are not deserving of reward!

The net result may of course be foretold from these data. There is much petty science, petty literature and petty art; but the more arduous labors which require the devotion of a lifetime are becoming increasingly difficult. The man of science is now exactly in the position in which writers and inventors found themselves before the copyright and patent acts were passed. He is never the master in his own house; he is the slave to institutions which "run him" for what he is worth; and is seldom able to spend his time in the exercise of the lofty gift which nature has given him. Still worse, the most capable minds are at the outset turned away from fields in which their efforts are likely to be of the highest value to humanity.

All this really springs from the curious and stupid attitude of the public towards all forms of intellectual effort. It seems to take no interest in such effort. Politics, game-playing and picture-shows are the things which amuse it. The great worker is a mere book-

worm, or a plodder, or a crank. But the truth is that, just as individuals have duties to perform to their country, so have countries duties to perform to the civilized world. It is the duty of every nation to participate in the discovery of the laws of nature, to ascertain the cause of disease, to enhance the powers of man, and to widen the range of his vision. What does Britain do to fulfil this duty? She still has great workers, it is true; but their work springs from themselves, and not from the nation. The country does not perform the duty referred to. It has become like a tradesman who has reached great wealth by the exercise of inferior arts, but who spends it on amusements, pleasures and the ostentation of charity, without sparing a penny for higher objects. This figure may at least be reached as a rough integration of the general complex formulæ of our present condition. Behind all there is a shadow: for nations, like individuals, must remain efficient.

EFFECT ON THE PROPAGATION OF ELECTRIC WAVES OF THE TOTAL ECLIPSE OF THE SUN, AUGUST 21, 1914

THE committee for radiotelegraphic investigation of the British Association for the Advancement of Science calls attention to the fact that the forthcoming total eclipse of the sun affords an exceptional and important opportunity of adding to existing knowledge of the propagation of electric waves through air in sunlight and in darkness, and across the boundaries of illuminated and unilluminated regions. The eclipse will be total along a strip extending from Greenland across Norway, Sweden, Russia and Persia to the mouths of the Indus. In Russia the duration of totality will be a little more than two minutes.

There are two main points calling for investigation during the eclipse. In the first place, the propagation of signal-bearing waves through air in the umbra and penumbra will probably obey laws different as regards absorption and refraction from those obeyed in illuminated air. In the second place, the strength, frequency and character of natural electric waves, and of atmospheric discharges,

may vary. The variations may occur either because the propagation of natural waves from distant sources is facilitated or impeded by the eclipse, or, possibly, because the production of natural electric waves or atmospheric discharges is for some unknown reason affected by the eclipse.

These points have previously been investigated to only a slight extent. The observers of signals during the solar eclipse of April 17, 1912, nearly all agreed that the strength of the signals was greater during the eclipse than an hour before or after. There was only one special observation of strays during the same eclipse, when very pronounced and remarkable variations were recorded during the passage of the shadow-cone across Europe.

To investigate the propagation of signals across the umbra it will be necessary to arrange for wireless telegraph stations on either side of the central line of the eclipse to transmit signals at intervals while the umbra passes between them. This transit of the umbra occupies about two minutes. It is thus very desirable that the Scandinavian and Russian stations should transmit frequently throughout several minutes before, during and after totality. But stations other than those favored by their proximity to the central line should endeavor to keep a complete record of the variations of signals during the eclipse. Stations in Europe west of the central line and stations in the Mediterranean and in Asia Minor may find noticeable changes in the strength of signals, particularly long distance signals, between the hours of 10 A.M. and 3 P.M., Greenwich time; and it is probable that the stations of India and East Africa, and ships in the Indian Ocean, may feel the effect of the penumbra in the afternoon. On the other hand, ships in the Atlantic, and fixed stations in Eastern Canada and the United States, will probably be affected by the penumbra in the early morning. At Montreal the eclipse (partial) is at its greatest phase at 5:52 A.M. standard time. It is possible that the eclipse may have some influence even when it is invisible.

The investigation of strays is of as great

interest as that of signals. So far as is yet known, the natural electric waves reaching wireless telegraph stations in latitudes higher than 50° appear to travel mostly from the south. Thus the greatest changes produced in strays by the eclipse will probably be experienced at stations in Scandinavia and Russia, to reach which the waves must cross the path of the umbra. At the same time changes of some kind are to be expected in other districts than these, and it is therefore desirable that statistical observations of natural electric waves be made all over the world, and especially at places within an earth quadrant of southern Russia. It is also desirable that meteorological observations, including those of atmospheric ionization and potential gradient, should be at the disposal of the committee when considering the records of strays and signals.

The committee proposes to prepare and circulate special forms for the collection of statistics of signals and strays, especially within the hemisphere likely to be affected by the eclipse; they will endeavor to make provision for the transmission of special signals at times to be indicated on the forms; and they will offer for the consideration of the authorities controlling stations near the central line a simple program of work. The discussion of the observations, and the comparison with meteorological data, will be carried out by the committee; and digests of the statistics, together with the conclusions drawn from the analysis, will be published in due course.

The committee would be greatly aided in the organization of this investigation if those possessing the necessary facilities and willing to make observations during the eclipse would communicate with the honorable secretary, Dr. W. Eccles, University College, London, W. C., at the earliest possible date.

THE NAPIER TERCENTENARY CELEBRATION

JOHN NAPIER'S "*Logarithmorum Canonis Mirifici Descriptio*" was published in 1614; and it is proposed to celebrate the tercentenary of this great event in the history of mathe-

matics by a congress, to be held in Edinburgh on Friday, July 24, 1914, and following days.

The celebration is being held under the auspices of the Royal Society of Edinburgh, on whose invitation a general committee has been formed, representing the Royal Society of London, the Royal Astronomical Society, the town council of Edinburgh, the faculty of actuaries, the Royal Philosophical Society of Glasgow, the universities of St. Andrews, Glasgow, Aberdeen and Edinburgh, the University College of Dundee, and many other bodies and institutions of educational importance.

Through the favor of the editor of *SCIENCE*, the president and council of the Royal Society of Edinburgh have now the honor of giving a general invitation to mathematicians and others interested in this coming celebration.

The celebration will be opened on the Friday with an inaugural address by Lord of Appeal Sir J. Fletcher Moulton, F.R.S., LL.D. (Edin.), followed by a reception given by the Right Honorable the lord provost, magistrates and council of the city of Edinburgh. On the Saturday and Monday the historical and present practise of computation and other developments closely connected with Napier's discoveries and inventions will be discussed. A memorial service will be held in St. Giles' Cathedral on the Sunday.

Among many who have expressed a warm interest in the celebration and who hope to take part in the congress, may be mentioned Professor Andoyer, Paris; Professor J. Bauschinger, Strassburg; Professor Hume Brown, Historiographer Royal for Scotland; Professor F. Cajori, Colorado, U. S. A.; Professor G. A. Gibson, Glasgow; Dr. J. W. L. Glaisher, Cambridge; Professor Lang, St. Andrews; Professor Macdonald, Aberdeen; Professor E. Pascal, Naples; Professor Karl Pearson, London; Professor Eugene Smith, New York; Professor Steggall, Dundee; Professor Whittaker, Edinburgh.

Merchiston Castle, the residence of Napier, has long been occupied by the well-known public school, which draws pupils from all parts of the British empire. The governors of

the school have kindly invited the members of the congress to visit the castle and grounds on the Saturday afternoon.

Relics of Napier, collected by Lord Napier and Ettrick and other representatives of the family, will also be on view; and it is intended to bring together for exhibition books of tables and forms of calculating machines, which may reasonably be regarded as natural developments of the great advance made by Napier.

Individuals, societies, universities, public libraries, etc., may become founder members on payment of a minimum subscription of £2; and each founder member will receive a copy of the memorial volume, which will contain addresses and papers read before the congress, and other material of historic and scientific value. It is important to secure as many founder members as possible, so that a volume may be brought out worthy of the memory of Napier.

Ordinary subscribers attending the celebration may receive copies of the memorial volume at a reduced price.

Subscriptions and donations should be sent to the honorary treasurer, Mr. Adam Tait, Royal Bank of Scotland, St. Andrew Square, Edinburgh.

All who are interested in this proposed celebration are respectfully invited to communicate with the general secretary of the Royal Society of Edinburgh, 22 George Street, Edinburgh, and to announce their intention of being present.

C. G. KNOTT,
General Secretary

ROYAL SOCIETY OF EDINBURGH

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE council met at the Cosmos Club, Washington, on Tuesday, April 21, 1914, at 5:45 P.M. In the absence of the chairman, Mr. Diller presided. Those present were: Messrs. Bowie, Cattell, Diller, Gulliver, J. A. Holmes, Howard, Humphreys, D. S. Johnson, John Johnston, Kober, Metcalf, Pickering, Shear, Trelease and Twitmeyer.

The financial report of the permanent sec-

retary was read and, on motion, was approved and ordered printed.

Mr. Cattell submitted the report of the committee on policy.

On motion, the following resolutions recommended by the committee on policy were adopted *ad seriatim*:

1. *Resolved*, that Professor Pickering be added to the committee on policy.

2. *Resolved*, that Dr. E. W. Allen, of the office of experiment stations, U. S. Department of Agriculture, be elected secretary of Section M (Agriculture) and that he be authorized, with Professor L. H. Bailey, vice-president of the section, to nominate the sectional committee for Section M and also its representative on the council.

3. *Resolved*, that the permanent secretary be instructed to inform Dr. Robert M. Ogden that no funds can be provided for the present for the associate secretary for the south beyond necessary clerical expenses.

4. *Resolved*, that the first of the Jane M. Smith life memberships be awarded to Professor Charles Henry Peck, of Albany.

5. *Resolved*, that the entrance fee be remitted to members of the Pacific Association of Scientific Societies who join the American Association during the present year.

6. *Resolved*, that the council authorize a grant of four hundred dollars to the Pacific coast committee for the expenses of its membership committee.

7. *Resolved*, that the council authorize the Pacific coast committee to adopt the constitution for the Pacific Division and that it be suggested that the second clause of the second paragraph of Article 3, beginning with the word "except," of the constitution submitted, be omitted.

8. *Resolved*, that the council give the treasurer full power to act for the association in the Colburn will case.

9. *Resolved*, that the council authorize the appointment of Messrs. Eliot, Minot and Pickering as a committee to take the necessary steps to amend the charter of the association increasing the amount of property which may be held by the association.

10. *Resolved*, that the clerical expenses of the committee of one hundred on scientific research and its subcommittees be met from the income from the permanent funds of the association.

11. *Resolved*, that the council welcomes the action of the council of the American Chemical So-

ciety favoring the plan of holding meetings jointly with the American Association at four-year intervals.

12. *Resolved*, that the publication of the constitution and list of members be postponed until January, 1915.

On motion, it was resolved that the sectional committee of Section C be empowered to elect its vice-president and chairman for the Philadelphia meeting in consultation with the committee on policy.

L. O. HOWARD,
Permanent Secretary

SCIENTIFIC NOTES AND NEWS

DR. GEORGE WILLIAM HILL, distinguished for his contributions to mathematical astronomy, has died at the age of seventy-six years.

DR. CHARLES SANTIAGO SANDERS PEIRCE, known for his work in logic and mathematics, died on April 19, aged seventy-four years.

THE National Academy of Sciences on April 22 presented its "medals for eminence in the application of science to the public welfare," to Colonel George Washington Goethals and Brigadier General William Crawford Gorgas. The presentation was made by Dr. William H. Welch, president of the academy, at a dinner held in honor of the retiring president, Dr. Ira Remsen, and the retiring home secretary, Dr. Arnold Hague.

MEMBERS of the National Academy of Sciences were elected at the annual meeting on April 23 as follows: Ernest Merritt, physicist, Cornell University; Moses Gomberg, chemist, University of Michigan; Edward Curtis Franklin, chemist, Stanford University; Frederick Leslie Ransome, geologist, U. S. Geological Survey; Nathaniel Lord Britton, botanist, New York Botanical Garden; Henry Herbert Donaldson, neurologist, Wistar Institute of Anatomy; Herbert Spencer Jennings, zoologist, The Johns Hopkins University; Francis Gano Benedict, chemist, nutrition laboratory of the Carnegie Institution; Walter Bradford Cannon, physiologist, Harvard University; Jesse Walter Fewkes, ethnologist, Bureau of American Ethnology.

At its annual meeting in Philadelphia on April 25, the American Philosophical Society elected to membership the following residents of the United States: Charles Greeley Abbot, Washington; James Wilson Bright, Baltimore; Bradley Moore Davis, Philadelphia; Thomas McCrae, Philadelphia; William Diller Matthew, New York; Alfred Goldsborough Mayer, Washington; Samuel Jones Meltzer, New York; John Campbell Merriam, Berkeley; Robert Andrews Millikan, Chicago; William Albert Noyes, Urbana; Stewart Paton, Princeton; Richard Mills Pearce, Philadelphia; Palmer Chamberlaine Ricketts, Troy; Harold A. Wilson, Houston; Frederick Eugene Wright, Washington. Foreign residents were elected as follows: Shibasaburo Kitasato, Tokyo; Heike Kamerlingh Onnes, Leyden; Vito Volterra, Rome.

PROFESSOR MOSES GOMBERG, of the University of Michigan, has been given the gold medal of the New York section of the American Chemical Society for his work on the trivalence of carbon.

PRINCE GALITZIN will preside over the fifth meeting of the International Seismological Association, to be held in St. Petersburg in September.

DR. J. D. FALCONER, lecturer in geography in the University of Glasgow, has been appointed by the trustees of the British Museum to the Swiney lectureship in geology, in succession to Dr. T. J. Jehu.

OLIVER BOWLES, of the department of geology and mineralogy, University of Minnesota, has been appointed quarry technologist in the division of mineral technology, Bureau of Mines, Washington, D. C.

DURING the absence abroad of Mr. William H. Fox, director of the museums of the Brooklyn Institute of Arts and Sciences, Mr. Robert Cushman Murphy, curator of mammals, is acting director.

THE German geographer, Dr. Ewald Banse, has started on an expedition for the exploration of the Libyan desert.

B. M. PATTEN, Ph.D., has received an appointment from the United States Fisheries

Department to go on the *Seneca*, a government patrol vessel, and make a study of the temperature, salinity and other qualities of the water of the ocean at various depths.

DRS. S. MARKS WHITE and Jennings C. Litzenberg, of the medical faculty at the University of Minnesota, are absent on leave the current semester. Dr. Frederick H. Scott, of the department of physiology, has been granted leave for the first semester of 1914-1915, and Professor Harold E. Robertson, of the department of pathology, has been granted a year's leave of absence during 1914-1915.

PROFESSOR B. SHIMEK, of the department of botany of the State University of Iowa, will carry on research work in Europe during the remainder of the year. He has been invited to deliver a series of twelve lectures, chiefly on the subjects of the plant ecology of the American desert and prairie, and the loess, at the University of Prague during the summer semester, 1914. He will also present two papers, by request, before the meeting of biologists and physicians to be held at Prague from May 31 to June 3.

PROFESSOR A. N. WINCHELL, of the University of Wisconsin, has returned from a visit to the Missouri School of Mines, the University of Kansas, the Agricultural College of Iowa and the University of Illinois. At each institution he delivered two lectures, one upon the "Mining Geology of the Butte District," and the other upon the "Origin of the Butte Ore Deposit."

THE Syracuse Chapter of Sigma Xi has held two open meetings during the past winter. At the first, on February 20, Professor M. I. Pupin, of Columbia University, gave an address upon the topic, "Wave Conductors," with especial reference to the so-called Pupin conductors which have made present-day long-distance telephony possible. At the second open meeting, March 6, Dr. Robert Almer Harper, professor of botany at Columbia University, gave an address upon the topic, "Studies in Morphogenesis." A large audience consisting of both university and city people, greeted each lecturer.

PROFESSOR E. HEYN, of Berlin, is this year to deliver the annual May lectures before the Institute of Metals, London, upon the subject, "Internal Strains in Cold Wrought Metals."

THE Friday evening meetings of the Royal Institution were resumed on April 24 when Dr. F. W. Dyson, the astronomer royal, lectured on the stars around the north pole. On May 8, Professor Karl Pearson will give an address on albinism in men and dogs; and on May 15 Professor Keeble will speak on "Plant Animals: A Study in Symbiosis."

THE department of anatomy at the University of Minnesota has issued two volumes of reprints of anatomical literature, by the following members of the department: J. B. Johnston, R. E. Scammon, W. F. Allen, W. A. Hilton, E. T. Bell, T. G. Lee, W. S. Nickerson, Robert Retzgar. Volume I. covers 1909-11 and Volume II., 1912-13.

THE University of Michigan has begun the publication of scientific papers of the museum of zoology, under the general title "Occasional Papers of the Museum of Zoology, University of Michigan." The papers are to be published separately, at irregular intervals, and will be numbered consecutively. The whole series will be sent through the university library to libraries and scientific institutions of a zoological nature, and the museum will distribute copies of each number to students interested in the subjects discussed.

THE twenty-third session of the Marine Biological Laboratory, of Stanford University, will begin on Monday, May 25. The regular course of instruction will continue six weeks, closing July 4. Investigators and students working without instruction may make arrangements to continue their work through the summer. The laboratory will be under the general supervision of Professor G. C. Price, instructor in charge. The laboratory provides for three classes of students: (1) Teachers and students who have not had the advantages of laboratory courses in zoology. (2) Advanced students in zoology and physiology who wish to continue their studies. (3)

Investigators who are prepared to carry on researches in morphology or physiology.

A SERIES of water-color plant studies painted by the late traveler and artist, Miss Adelia Gates, and presented to the Smithsonian Institution by her niece, Miss Eleanor Lewis, of Yellow Springs, Ohio, is now exhibited in the new building of the U. S. National Museum. The subjects treated embrace a wide range of foreign and domestic plants painted by the artist in this country and abroad. Some additions have recently been made to the original deposit by the donor who has endeavored to bring together all the flower studies made by Miss Gates, many of which were widely distributed by her prior to her death. With these additions, the collection now numbers some 600 paintings.

WE learn from *Nature* that a collection of rock specimens of considerable historic interest has been presented to the department of minerals of the British Natural History Museum. The specimens in question were collected in Arctic North America by Sir John Richardson, who accompanied Sir John Franklin's Arctic expeditions of 1819-1827. They have since that time been kept in the museum of the Royal Naval Hospital at Haslar, but inasmuch as the fossils collected in the same Arctic expeditions are in the National Museum at South Kensington, it was felt to be in the fitness of things that the rocks should be also preserved there. An application was accordingly made to the Lords of the Admiralty to sanction the transfer of the specimens.

FROM June 23 to 30 there will be held in London, as we learn from the *London Times*, the third annual International Congress on Tropical Agriculture, promoted by l'Association Scientifique Internationale d'Agronomie Coloniale et Tropicale. This society was formed with the idea of helping associations formed in tropical colonies for the development of their agriculture to study in common fundamental problems connected with the successful growing of important natural tropical products, such as rubber, tea, coffee, cocoa,

tobacco, cocoanut oil, cotton, jute, sisal hemp and cinchona. The value of the results expected from the congress may be gauged by the fact that on the organizing committee practically every tropical colony in the British Empire is represented by its principal agricultural officer. Official notifications are being sent out by the British Foreign Office and the Ministère des Affaires Etrangères in Paris to the governments of all countries possessing tropical colonies inviting them to appoint official delegates. The congress is to meet at the Imperial Institute, South Kensington, and among the subjects suggested for papers and discussion are: Technical education and research, labor organization and supply, rubber production, development of cotton-growing, fiber production, agricultural credit banks, agriculture in arid regions, tropical hygiene and preventive medicine, plant diseases and pests, and so forth. Numerous papers on these and kindred subjects have been promised by well-known experts. Professor Wynham R. Dunstan is the chairman of committee, and Dr. T. A. Henry and Mr. H. Brown, of the Imperial Institute, are the honorary secretaries.

Two models which show how the government sells its timber have just been prepared in Washington, for display at the forest products exposition, to be held in Chicago, April 30 to May 9, and in New York, May 20 to 30. These models represent an acre of western yellow pine land in a national forest of the southwest before and after logging. In the model showing the stand before the lumberman goes into it the trees range from those only a few years old to large, overmature, stag-headed individuals more than ready for the axe. In the second model the mature trees and all others larger than a certain diameter have been cut down and made into logs and cordwood. In this, as in all government sales, the stumps are cut low to avoid unnecessary waste, logs are taken to a small diameter well up into the tree, and such material as is not fit for lumber is converted into cordwood. Together, the models show the care which the government requires of lumbermen in felling

old trees so that the young growth is not injured. The brush is piled in heaps for burning after the lumber has been removed, in order that the fire menace which foresters say usually follows lumbering may be done away with. The models are on a scale of about one inch to five feet, so that trees approximately 100 feet tall are about 20 inches high in the models. It is the intention of the forest service to have these models set forth certain points in regard to the timber sales conducted by the government. They will demonstrate, in the first place, that the timber on the national forests is for use; placards tell how it is sold to the highest bidder when it is wanted for commercial purposes, and how it may be given away to local settlers and prospectors for developing homesteads or mines. The models themselves indicate that the timber is cut in such a way as to eliminate all avoidable waste of wood and to secure a continuance of the forest crop, not only for timber production but for the protection of the soil. They further show the fundamental principles applicable to many logging operations, that the mature and overmature trees should be removed, that thrifty growing young trees should be left to produce seed and insure a reproduction of the stand, and that the young growth should be protected from damage in lumbering operations. The models are supplemented by a graphic chart, which shows by pictured piles of money and by conventional trees of graded size the increase of timber sales on the national forests from 1905 to 1913, inclusive. In 1905 the timber sold from the national forests aggregated 96,000,000 board feet, which brought the government no more than \$85,000. Three years later the amount of timber sold increased to nearly 390,000,000 board feet, and the money received rose to \$735,000. In 1911 830,000,000 board feet sold for more than \$2,000,000, and in 1913 more than 2,000,000,000 feet brought in contracts amounting to \$4,500,000. Not all this money was received in any one year, because national forest timber is sold on contracts which range from one to twenty-five years, and it is paid for as cut.

UNIVERSITY AND EDUCATIONAL NEWS

THE Catholic University of America, Washington, will receive the greater part of the estate of \$1,000,000 left by Theodore B. Basselin, of Croghan.

MR. JAMES DEERING, in a letter addressed to the trustees of Northwestern University and of Wesley Hospital, announces a gift of \$1,000,000 to the hospital. It is provided that Wesley Hospital shall be a teaching hospital under Northwestern University. The gift is made in honor of the donor's father, the late William Deering, and his sister, Abbie Deering Howe, who died in 1906.

AN anonymous benefactor has given a sum of \$1,200,000 to the municipality of Berlin for the foundation of an open-air school for boys. In the course of instruction special attention will be given to modern languages and natural science.

ARTHUR TABER JONES, Ph.D., has been appointed assistant professor of physics at Smith College.

HENRY LAURENS, Ph.D., has been appointed instructor in biology, and George A. Stetson, instructor in mechanical engineering at Yale University.

AT Harvard University, Dr. W. E. Hocking, professor of philosophy at Yale University, has been appointed professor of philosophy, and Dr. R. F. A. Hoernle, of the University of Durham, assistant professor of philosophy. Dr. E. M. East has been promoted to be professor of experimental plant morphology and H. J. Hughes, to be professor of civil engineering. Dr. S. B. Wolbach has been promoted to be associate professor of bacteriology and Dr. C. L. Bouton to be associate professor of mathematics.

THE executive committee of the Massachusetts Institute of Technology has made the following promotions in the instructing staff: From the grade of associate professor to the grade of professor, Warren K. Lewis, in chemical engineering; George B. Haven, in machine design; Samuel C. Prescott, in industrial biology, and Charles B. Breed, in railroad engineering. The following assistant

professors have been advanced to the grade of associate professor: Carroll W. Doten, in economics; A. A. Blanchard, in inorganic chemistry; S. M. Gunn, in sanitary biology and public health; A. T. Robinson, in English; A. G. Woodman, in food analysis. The following instructors have been advanced to the grade of assistant professors in the departments indicated: Charles W. Green, in electrical engineering; Henry H. W. Keith, in naval architecture; John F. Norton, in chemistry of sanitation; Joseph W. Phelan, in inorganic chemistry; George W. Swett, in machine design, Frederick H. Lahee in geology. Assistants advanced to the grade of instructors are: Ralph G. Adams, in mechanical engineering; Arthur E. Bellis and Charles L. Burdick in theoretical chemistry; Edward A. Ingham in biology; Norman Osann in electrical engineering, and DeWitt M. Taylor, in mechanical engineering.

DISCUSSION AND CORRESPONDENCE

INTERPRETATIONS OF THE ANOMALIES OF GRAVITY

UNDER this title Mr. G. K. Gilbert discusses¹ the investigations of Messrs. Hayford and Bowie² (of the Coast and Geodetic Survey) relating to terrestrial gravity, and its application to observed earth movements by J. W. Spencer.³ Any consideration of such important new problems should be welcomed as they tend to confirm previous results, or show their weakness or the lack of information.

Hayford and Bowie have stated that, for the purpose of making computations, the earth's

crust is assumed to be in a state of perfect isostasy. They show, contrary to Gilbert's ideas on the subject, that while this is true for the whole area of the United States, there are large areas where the anomalies depart slightly from the perfect balance and smaller areas where the anomalies are considerable. This last is the special feature of Spencer's application of the anomalies of gravity to earth movements. Thus, at Washington, the excess of gravity is equal to 1,200 feet, while the deficiency at Virginia Beach (160 miles distant) is equivalent to a thickness of 1,600 feet of rock.

Hayford and Bowie have found that the topography is all compensated within a depth of 122.2 kilometers below sea-level (although they used 113.7 km. in their gravity computations); that is, the condition of stress at and below the depth of compensation is isostatic, or in other words "any element of the mass is subject to equal pressures from all directions as if it were a perfect fluid." Gilbert has misconstrued their conception of this, for he states "immobility at all depths below that of compensation is either explicitly or implicitly assumed by Hayford and Bowie." He also appears to take the view that even very small areas are completely compensated, and that much of the compensation in the vicinity of the stations, with decided or large anomalies, is located in the nucleus. This view is untenable as shown by such anomalies as those of Washington and Virginia Beach, or still greater ones between Olympia and Seattle. This compensation, located in the nucleus, presupposes very high rigidity, which is contrary to the idea of complete local isostasy, which on the other hand presupposes great plasticity.

Gilbert discusses the causes of the anomalies, favoring the one based upon the local variation of density of the column and heterogeneity of the nucleus with a sub-crustal mobile layer, which accounts for the isostasy. But all materials of the earth's crust are mobile under long-continued stress differences, yet there is sufficient rigidity in the crust to sustain local anomalies.

In his discussion, Gilbert assumes that the nucleus is composed of the same materials as

¹ U. S. Geological Survey, Professional Paper 85-C, pp. 29-37.

² Hayford, J. F., and Bowie, William, "The Effect of Topography and Isostatic Compensation upon the Intensity of Gravity," U. S. Coast and Geodetic Survey Special Pub. No. 10, Washington, 1912; Bowie, William, "Effect of Topography and Isostatic Compensation upon the Intensity of Gravity," *id.*, Special Pub. No. 12, Washington, 1912.

³ Spencer, J. W., "Relationship between Terrestrial Gravity and Observed Earth Movements of Eastern America," *Am. Jour. Sci.*, 4th ser., Vol. 35, pp. 561-573, 1913.

those of the crust, and that the great density of the earth (5.6) is due to "compression by pressure," in spite of the remarkable incompressibility of even water, with the interior heat acting contrariwise. The most commonly accepted view of the great weight of the nucleus of the earth is that it is composed of heavy metallic substances; for instance, astronomer Ball regards meteorites as the remains of disrupted planets such as would be liberated by the explosion of the earth.

Concerning the relationship between the anomalies of gravity and earth movements, Dr. Gilbert says:

Spencer emphasizes the fact that there are large plus anomalies within the region once covered by the Laurentian ice and regards it as proof that the rising of the region after the removal of the ice load was not caused by the removal of the load.

Again he says:

The fact (of plus anomalies within this area) may equally be used to discredit the hypothesis underlying his mode of interpreting anomalies.

These statements give neither the facts nor arguments upon which Spencer bases his hypothesis that the anomalies are not due to the removal of an ice load, nor how the facts discredit his hypothesis. Observing that the plus anomaly (equaling 700 feet of rock) north of the Adirondacks, and the deformation (of 650 feet) of the earth's crust as seen in the tilted beaches, closely agree, Spencer naturally concluded that there is a direct relationship between the two phenomena. Farther south in the Adirondacks, composed of dense rocks, the anomaly of gravity is reduced to 200 feet of rock. Southward from this and extending over a very great region once covered by ice the anomalies show deficiency of weight. If the deformation adjacent to the St. Lawrence River were due to the removal of the ice sheet, then the region to the south should also have been elevated to isostatic equilibrium.

Supporting Spencer's conclusions, from evidence lying outside of the glaciated region, the Appalachian belt and Florida are over-weighted, although much material has been removed from the mountains. On the other hand, the coastal region is found to be under-

loaded, although it is here that the deposition of the materials, brought down from the mountains, have accumulated. This under-loading agrees with the subsidence shown by the canyons and valleys indenting the submarine border of the continent. Yet this collateral evidence is not considered by Gilbert.

The observation of all these features is of comparatively recent date, yet they have the greatest value, although they are contrary to the hypothesis that the mobility of the earth's crust is so complete that areas of considerable size can not either be loaded or unloaded, without being fully accounted for in the isostatic balance. The phenomena of earth movements and of anomalies of gravity introduces new features in the evolution of our continents, which have only begun to be investigated.

It may be added that Professor Leverett and also Mr. Taylor have just announced that they have found moraines in the lake region, in disagreement with the hypothesis that the deformation of the earth's crust is due to the removal of the ice—results in accord with relationship of the anomalies of gravity and earth movements as lately first described by the present writer.

J. W. SPENCER

HEADS OF DEPARTMENTS: A COMMENTARY UPON DR. JOHNSTON'S ARTICLE

It was very wholesome reading that Doctor Johnston offered the heads of departments in his article upon University Organization, appearing in the December 26 issue of *SCIENCE*, p. 908. The unfortunate conditions described so truly he evidently finds existing not in any one special institution, but in many.

Any fair-minded head realizes the disadvantages under which younger members of his staff labor. Unfortunately, there are many professors who are quite content to allow their associates to remain unheard and unheeded, either because they honestly (and ignorantly) believe them lacking in wisdom or because they fear the effect of allowing them to be in the least prominent. For such, as well as for the more liberally inclined,

Doctor Johnston's frank utterances are of benefit and form an integral part of many present-day expressions which, no doubt, will result in bettering conditions in universities.

Some readers of the article referred to might perhaps have desired more detailed expression in the author's constructive paragraphs. He fails, in the estimation of the undersigned, to give in sufficient detail, suggestions for the relief of the situation in general existing between a head of department and his staff, although it is this feature which he particularly criticizes in the article referred to. In just what position, for example, should a head regard his men, with reference to their responsibilities? In how far would the Doctor make them independent of the head, that is, free to act upon their own initiative, without first obtaining the sanction of the chief, etc.?

A detail included in Doctor Johnston's broad generalizations and annually clamoring for relief is as follows: A head, in recommending a member of his staff for advancement, either in rank or salary, is almost invariably and perhaps sometimes unconsciously influenced by prejudice. The man of pleasing personality or with a possible close social connection or representing a particular phase of the work in which the head is interested is the one recommended for promotion, although others on the staff are perhaps more useful to the institution and more deserving than the party fortunate enough, for reasons above stated, to be close to the chief. What measures of relief for this condition would Doctor Johnston advise?

We know of one department where the staff, rebelling at the recommendation made by their head, drew up and submitted to their president counter resolutions recommending a fellow member other than the one favored by their chief. But for the president to give heed to such mutinous (?) expressions, when, as the Doctor shows, he is dependent upon the various heads, would be destructive to all system and discipline.

The author intimates that men of a department should be at liberty to discuss matters of their division or department freely with

the dean of a college or even carry their criticisms and complaints to higher officials. Arguing by analogy, we must assume that he would have the heads do the same—namely go around their dean and lay their woes before a president or even, disregarding the latter official, go directly to the board of regents. We hardly believe that such a system or, rather, lack of system, was in the author's mind at the time he wrote the lines referred to. If so, on the principle of "What is sauce for the goose, etc.," it would appear only right that, if the dean of a college should consult the members of a department, disregarding the head, he should expect an equal disregard of professional etiquette on the part of a head.

We doubt also whether Doctor Johnston, when he states, referring to "the results of arbitrary power placed in the hands of single men without check or publicity" that "such a system always breeds dishonesty and crime," really refers to conditions in any *university*; if such is the case, he uses somewhat strong language. One might, at this point, be a bit facetious, and we are tempted to ask the Doctor what, in his opinion, the result would be if this arbitrary power were placed in the hands of married men?

Without, in any way, taking issue with the excellent article referred to, it suggests certain phases of the problem which Doctor Johnston did not discuss and which we mention here at the risk of being regarded presuming—believing that the subject is one which merits free expression from all standpoints.

This thought occurs to the writer. The head of a department is generally several years the senior of his men and with that seniority *should* go a maturity of judgment born of an experience generally lacking in the younger men. Further, allowing that all the undesirable traits listed by Doctor Johnston may exist in a head, are we not liable to find just as many or more undesirable characteristics in the numerous young minds under him with the additional factor that the younger minds of the staff have not reached that point in development where they can see the futility of such characteristics?

Again (and here is a weakness in some heads, fortunately of rare occurrence, which Doctor Johnston fails to take cognizance of), we sometimes see the head of a department seeking to climb into favor with a dean, president or board of trustees at the expense of another department or other departments, by depreciating the work of others, by ridiculing or criticizing suggestions not emanating from his own department, by intimations and even fabrications regarding the efficiency of an associated department, etc. Fortunately, this characteristic on the part of a head is rare, although the fact that it does exist in institutions is apparent to almost any worker who has been connected with universities for twenty years or more.

Now, then, admitting that this weakness exists in some heads and realizing that characteristics of this kind are found more or less in many men, must we not admit the possibility of the same existing in the minds and characters of one, two or several of the men under a head? Do we not see young men in the profession, desiring prominence and advancement in a department, impatient, selfishly critical of their chief, undermining his position when possible, with the hope of personal advancement and so jealous of their associates of equal rank as to resort to ridicule or fabrication at their expense, if it appears to them necessary for their personal ambition? This view, of course, is an extreme one—purposely so—that we may in taking to heart Doctor Johnston's excellent remarks, not fail to see the other side of the question.

We know young men to-day—men of pronounced mentality—hypercritical of their chief and insistent upon the merits of their own views of administration—views which they might radically change after attaining maturity of experience. Some of these young men are of such self-satisfied temperament that, in years to come, if they attain positions of authority to which they aspire, they will be more dictatorial in their departments and more hide-bound in their views than the chiefs whose views they now seek to belittle.

Perhaps enough has been said to indicate to us, using, in part, a time-worn phrase, that there may be a middle course and that, in swinging from the rocks on one side of the strait, care should be taken to prevent collision with the opposite shore.

The efficiency of a department is, of course, the standard by which it is judged in the up-building of a university. What better basis is there than its ability to give graduate work? We know of an institution fortunate in the possession of a dean of its graduate school who, with remarkable ability in this particular line, has, by many means, not necessarily through the heads, acquainted himself with the powers in this direction, exhibited by the various departments in his institution. His records are, therefore, an index of the comparative merits and demerits of different departments and will doubtless be used for reference when occasion demands. Does this not show a tendency to get away from the autocracy of the present system?

In the writer's own department, a most happy condition, recently inaugurated, prevails. The leading members of the staff are section heads, each with his own particular line of work, his own experimental projects, his own employees, his own budget. The responsibility of expenditures and results rests directly upon the section head and he is judged accordingly. The chief of the department has a general oversight over the work of his staff and is in charge of the executive work of the division. Regular meetings of the staff, with the chief of the division as chairman, are held for the purpose of transacting business pertinent to the division, such as the approval of projects or of publications, by vote; plans for the betterment of work, courses given in college, etc., etc., and it has been found that fostering a cooperative spirit upon the part of the men and emphasizing their individual responsibility gives far better results than the opposite policy—one which is still followed (sad to relate) by department heads who have not yet "seen the light." UNIVERSITY OF MINNESOTA,
MINNEAPOLIS, MINN.

SCIENTIFIC BOOKS

Gruppenweise Artbildung. By HUGO DE VRIES, Professor of Botany in Amsterdam. Berlin, 1913. Verlag von Gebrüder Borntraeger. Pp. viii + 365. Figs. 121. Colored plates 22. Price 24 marks.

Somewhat more than ten years has passed since the appearance of the first volume of "Die Mutationstheorie" and we are most fortunate to have from Professor De Vries another book that is an extension of the former discussion and that also brings forward a remarkable body of new observations of very great interest to the workers in genetics. It is not often that an investigator is able to follow an earlier work of the scope of "Die Mutationstheorie" with a book of as great import, yet we have in "Gruppenweise Artbildung" a volume that perhaps outranks the first contribution in matter and in exposition. It will surprise even the students of *Oenothera* to note the remarkably wide range of crosses among these forms that De Vries has made and the extraordinary mass of observations that he has accumulated. These are carefully indexed and readily accessible for reference.

The first part deals with the origin of species by mutation. This is a summary of the views developed in "Die Mutationstheorie" with De Vries's answers to various criticisms that have been expressed to about the year 1912. There has been no essential change in his interpretation of the "mutations" from *Oenothera Lamarckiana*, an explanation of which is offered by a somewhat more detailed statement of his theory of intracellular pangenesis. Pangens are assumed in any individual to be in an active, inactive or labile state, and mutations arise when they are in the labile condition.

As to the status of *Oenothera Lamarckiana*, De Vries stands by his original position. It is to him representative of a wild species of American origin. Papers of the reviewer concerning the identity of Lamarck's plant of 1796 and on the problem of the origin of the *Lamarckiana* of De Vries's cultures have appeared too recently to find a

place in his discussion, and probably for the same reason there is no discussion of the studies of Heribert-Nilsson. De Vries takes a clear position against the view that the "mutants" of *Lamarckiana* represent the splitting of a hybrid form. He believes that hybrids between species of *Oenothera* breed true as illustrated by his reported observations on the cross between *biennis* and *muricata*. When an *Oenothera* cross gives a wide range of variants in an F₁ generation, as in the case of the hybrids between *grandiflora* and American types of *biennis*, De Vries apparently assumes that a mutating habit has descended from one or both of the parents.

Part two, treating of reciprocal and double reciprocal crosses, gives in detail the data upon which the conclusions reported by De Vries in 1911 were based. *Oenothera biennis* and *O. muricata* of Holland are two well-defined species, readily distinguishable, which breed true. Their reciprocal hybrids exhibit constant and marked differences and in the most striking of their vegetative characters strongly resemble the pollen parent. So uniform is this behavior that De Vries expresses the results with respect to the characters concerned by two formulae— $b \times m = m$, and $m \times b = b$. The important peculiarity of these hybrids is then the fact that they differ sharply from one another to a degree very unusual in reciprocal crosses. Furthermore, the reciprocals are reported to breed true without exhibiting variation in the F₂ generation as might be expected.

These reciprocal crosses may be crossed with one another in two ways to give double reciprocals—(*biennis* \times *muricata*) \times (*muricata* \times *biennis*), and (*muricata* \times *biennis*) \times (*biennis* \times *muricata*). When this is done the contrasted characters of the parent type which occupies the center of the formula appear to drop out and the resulting double reciprocal hybrid presents the characters of the parent which occupies the peripheral position. Expressed in simple formulae, which only apply to the vegetative characters under consideration— $(b \times m) \times (m \times b) = b$, and $(m \times b) \times (b \times m) = m$. The products of the double

reciprocal crosses, like the reciprocals, also breed true.

Modifications of the double reciprocal crosses, termed by De Vries sesquiereciprocals, may be made by combinations of the reciprocals with the parents in such a manner that similar parent types occupy the periphery of the formulæ— $b \times (m \times b) = b$, $(b \times m) \times b = b$, $m \times (b \times m) = m$, and $(m \times b) \times m = m$. Other arrangements with the peripheral positions of the formulæ occupied by different parent types give iterative hybrids— $b \times (b \times m) = m$, $(m \times b) \times b = b$, $m \times (m \times b) = b$, and $(b \times m) \times m = m$.

The explanation of this remarkable behavior is not as yet determined. An attractive hypothesis postulates the differentiation of classes of gametes carrying the characters of the parents in pure form and their appropriate combinations either by selective fertilization or through the elimination of such gametes as do not fit into the assumed schemes of combination. But these and other speculations must await the results of cytological studies as well as further experimentation. An interesting peculiarity of these crosses is their very high degree of sterility and it remains to be seen whether the same phenomena will be found in other *Oenothera* species crosses that are more fertile. Thus it is possible that numerous and varied types of gametes may be developed by the hybrids, as theoretically would be expected, but that physiological conditions will allow only certain types to mature or function.

A long and detailed account of twin hybrids constitutes the third part. These classes of hybrids were first discovered by De Vries among hybrids of *Lamarckiana* with other species of *Oenothera*. He has since greatly extended his observations and finds twin hybrids also differentiated when certain "mutants" from *Lamarckiana* are similarly crossed (e. g., *nanella*, *lata*, *scintillans*, *oblonga* and also *lævifolia*). *Brevistylis* in such crosses follows a Mendelian ratio and *gigas* gives intermediate hybrids. The twin hybrids appear in the first hybrid generation which consists of two sharply contrasted groups. In

one group, termed *læta*, the characters of *Lamarckiana* are strongly dominant over those of the other parent. In the other group, termed *velutina*, the characters of the other parent dominate those of *Lamarckiana*. The proportions of the *læta* and *velutina* types appear to vary greatly in different cultures. The *velutina* types breed true in the second and later generations, but the *læta* forms were found in certain cultures to split off new lines of *velutina* in successive generations.

Another pair of twin hybrids, very different from *læta* and *velutina*, are distinguished as *densa* and *laxa*. They appear in crosses between certain broad-leaved forms of American *biennis* and *cruciata* with *Lamarckiana* or its "mutants." The distinctions here concern chiefly the form of the foliage and the number of capsules over a given length of stem; *densa* is broad-leaved with thickly crowded capsules, *laxa* has smaller leaves and capsules less numerous. The *densa* type breeds true, the *laxa* throws off in successive generations still another form, *atra*, distinguished by dark green leaves.

With the twin hybrids may be found a class of delicate and dwarfed plants, the seedlings of which are etiolated. These are named *gracilis* and they are present in very diverse proportions. Very many of the *gracilis* types die as seedlings, a few with care may be brought to maturity as narrow-leaved plants mostly sterile. The classes of dwarfs that the writer has reported for a number of crosses between *grandiflora* and American *biennis* may correspond to this group. Finally among the twin hybrids are occasionally found plants of marked size or luxuriance which appear to hold to the cultures as a whole a relation somewhat similar to that of *gigas* or *semi-gigas* to *Lamarckiana*. This type is called *hero*.

De Vries offers an explanation of twin hybrids, and of the *gracilis* and *hero* types through his theory of mutation and intracellular pangenesis. Mendelians may attempt to find in the phenomena the results of recombinations of multiple factors, although they will have difficulties in working out consistent

ratios. Others may be satisfied with an elastic view that allows of profound interactions of factors upon one another with their material modification in the "melting pot of cross breeding."

The lengthy fourth part is an examination of the chief new species of De Vries's cultures as to their behavior in crosses, with special reference to an explanation of this behavior on the theory of intracellular pangensis. An immense amount of detail is presented, well sifted, however, by the summary and conclusions. It is interesting to note that of these new species *gigas* alone is considered as progressive; *brevistylis*, *rubrinervis* and *nanella* are regarded as retrogressive, *lata* and *scintillans* as degressive, and *oblonga* as anomalous.

Finally a fifth part on the cause of mutation gives us the latest statement of De Vries's position. This part consists of discussions of a number of topics related to other portions of the book or to earlier publications of the author, and constitutes a general summary. "Gruppenweise Artbildung" results from a gradual accumulation of mutations on the part of a species, and hybridization to De Vries includes a very much wider range of phenomena than the types interpreted by Mendelian analysis.

A comprehensive bibliography of *Oenothera* experimental literature, a full and very valuable citation of the crosses that De Vries has personally made among the *Oenotheras*, and an excellent index complete the volume. The 121 text-figures throughout the book are of an unusually high grade, and the 22 colored plates admirably executed. It is greatly to be hoped that the author and publisher will promptly arrange for an English translation.

BRADLEY M. DAVIS

Monographia Uredinearum seu specierum omnium ad hunc usque diem cognitarum descriptio et adumbratio systematica. By P. and H. Sydow. Volumen III., Fasciculus I.: Pucciniaceæ, cum 7 tabulis. Lipsiæ, Fratres Bornträger. 1912. 8vo. Pp. 1-192.

The appearance of the first part of the third volume of the "Monographia Uredinearum" by P. and H. Sydow has been of especial interest to mycologists because it has given the first bit of information concerning the classification which the authors are following, or propose to follow, in this work. The two earlier volumes (Vol. I., Genus *Puccinia*, 1902-4; Vol. II., Genus *Uromyces*, 1910) were entirely taken up with the treatment of two genera, *Puccinia* and *Uromyces*, without the slightest hint as to how they were to fit into any general arrangement. It seemed evident from the beginning that these two genera were given preferences on account of their size and popular importance and not because they might appear in that order in any scheme of classification. The correctness of this surmise is now well shown. The third volume is begun with a key to the genera of the family Pucciniaceæ, a total of twenty-five being recognized. In this key *Uromyces* is number 8 and *Puccinia* number 10. In the preparation of a work of this nature there are many obvious advantages in not being hampered by the publication of a key at the start, before all of the genera are fully studied, which must thereafter serve as a guide. The freedom with which these authors began their task they have deliberately relinquished, for they are here-with publishing a key to twenty-five genera although the descriptive accounts to date only cover fully the first sixteen of them.

To do the monographic work first and follow it with a key will, however, evidently not succeed in eliminating difficulties, as is evidenced by an examination of the present part. For example, one finds that the genera *Uropyxis* and *Diorchidium* are recognized in the key as valid, although they have been treated already in previous parts as synonymous with *Puccinia*. With the exception of these four genera, which have been treated previously, the present part takes up the genera in the order of the key and proceeds as far as the generic description of *Uromycladium*, which is the sixteen-th genus.

The genera in the order of their appearance are as follows, *Gymnosporangium*, *Hamasopra*,

Gymnoconia, *Phragmidium*, *Phragmopyxis*, *Blastospora*, *Rostrupia*, *Triphragmium*, *Hapalophragmium*, *Sphaerophragmium*, *Anthomyces*, *Uromycladium*. These are distributed among the three subfamilies, Phragmidiæ, Uropyxidæ and Pucciniæ, into which the family is divided. The limitation placed on these subfamilies has not been very rigid, for the genus *Triphragmium* is included in two of them, the Phragmidiæ and the Pucciniæ. The authors, however, state that they are uncertain regarding the place which *Triphragmium*, *Hapalophragmium* and *Sphaerophragmium* should occupy in their key. The remaining genera of the family Pucciniaceæ are *Dicheirinia*, *Gervasia*, *Hemilea*, *Ravenelia*, *Neoravenelia*, *Kuehneola*, *Pucciniostele*, *Skierka*, and presumably we may expect the next part to deal with them in the order given.

The classification shows conservatism on every hand and especially in the selection of the characters upon which it is founded. The old idea of the importance of the teleutospore is maintained. Such a method can be made to work very well as long as only the common things are considered from a "practical standpoint," but when all forms are considered from a scientific standpoint it can not be said to have much in its favor. The result in the present key is uncertainty and lack of uniformity. The attempt to arrange the key in such a way as to show relationships of the genera is highly desirable, but is not attained when the boundaries for genera are so loose that species contained within them admittedly indicate relationships to different subfamilies. But the composite character of genera can not be avoided with the one character scheme as a basis for grouping. Neither can the segregation of closely related forms be prevented as long as this system is maintained. The purely artificial character of number of cells in the teleutospores will throw forms which are of undoubted relation into different genera. Numerous examples illustrative of this feature have already been cited in the literature¹ and more are constantly being found as care-

ful comparisons are made. An arrangement which places the peach and plum rusts in the genus with *Puccinia graminis* and then separates a few forms from *Puccinia* into the genus *Rostrupia* may be "practical," but if it is any way natural it must be accidental. If *Rostrupia* which differs from *Puccinia* only in having the teleutospores with 3 or 4 cells should be maintained, it is not clear why several of the species of *Gymnosporangium* which have more than 2 cells should not be separated into a genus by themselves, or why the old genus *Phragmidium* should not be broken up into several genera, since the number of cells in the teleutospores in this group is highly variable. If the forms on Rosaceous hosts which have 2-several cells are worthy of generic standing outside of the ordinary *Puccinia* and *Rostrupia* genera, then it is not clear why the 1-celled forms on these hosts should not be separated from *Uromyces*, but such has not been done.

The bulk of the part is taken up by the genera *Gymnosporangium* and *Phragmidium*, 136 out of 192 pages being devoted to them and divided nearly equally between them. The monograph of *Gymnosporangium* is of interest in comparison with the one published by the writer about a year earlier as a Bulletin of the New York Botanical Garden.² The order of arrangement of the species, the plan of the keys, and the form of the descriptive accounts are the same as introduced in the writer's bulletin. Three additional species are included in the Sydow monograph, all described since the appearance of the writer's publication and founded on material not seen by him. As to the validity and relationship of the species there has not been the slightest disagreement. With one or two exceptions it is also to be noted that the specific treatment of the *Phragmidium* group is identical, so far as North American species are concerned, with Arthur's account in the Uredinales, "North American Flora." The latter, however, refers some of the species to other genera, *Earlea*, *Kuehneola*, while the Sydows refer all to the genus *Phragmidium*.

As regards certain nomenclatorial questions,

¹ Arthur, *Mycologia*, 4: 54-56, 1912, and Orton, *Mycologia*, 4: 194-204, 1912.

² Vol. 7, No. 26, 1911, pp. 391-483.

it is to be regretted that no such agreement of opinion can be recorded. When a full list of synonyms is included, as in the monograph, no great difficulty is likely to be experienced even when different authors choose to select different names as the one to be maintained, and yet instances will arise which are deplorable. The very first species in this third volume of the Sydow monograph raises some questions. They reject for it the writer's combination, *Gymnosporangium Blasdaleanum* (Diet. & Holw.) Kern, although that specific name is without question the oldest, presumably because it was founded on an æcidial stage, *Æcidium Blasdaleanum* Diet. & Holw. They also refuse to admit for this species another combination of the writer, *G. Libocedri* (P. Henn.) Kern, although this is founded on the "all important" teleutospore stage and is the oldest specific name thus applied. Henning³ used the combination *Phragmidium Libocedri*, cited his specimen in full, and accompanied it with an adequate description. He was in error in suggesting that *Gymnosporangium Libocedri* Mayer was the same as his plant, and we can not say that he transferred the Mayer name to *Phragmidium*, but he nevertheless very evidently did intend to apply the name *Phragmidium Libocedri* to his plant and he characterized it accordingly. To reject this specific name because he did not specially propose it *as new* seems to be a motive which is contestable and of little import. Such a procedure not only seems illogical, and is not only not followed by most botanists, but in many similar cases not by the Sydows themselves. They accept *G. Sorbi* Kern, *G. Harknessianum* Kern, *G. Photinæ* Kern, *G. hyalinum* Kern, *G. tubulatum* Kern, *G. transformans* Kern and *G. bermudianum* Earle, although not one of these was proposed, as a new name in the genus *Gymnosporangium*! They were all transfers of æcidial names as is evidenced by the inclusion of the original authors' names in parenthesis or the words *comb. nov.* Why not say that in these instances the establishment of names has not been accomplished if one re-

fuses to recognize æcidial names and there has been a failure to propose them in *Gymnosporangium* as new? In the case of *G. Amelanchieris* Ed. Fisch. the matter is somewhat different, for although *Amelanchieris* is a name proposed by de Candolle for the æcidial stage of the plant to which it is now applied, Fischer distinctly stated that he was not transferring de Candolle's name, but proposing another just like it as new. This appears to satisfy the conditions which it seems that the Sydows would like to impose and yet in this very instance they have given evidence that they did not regard Fischer's name as a new one but as a transfer, for their Uredineen No. 2287 was issued as *Gymnosporangium Amelanchieris* (DC.) Ed. Fisch., with *Æcidium Amelanchieris* DC. given in parenthesis as a synonym. To go back again to the first species it is to be noted that the authors after rejecting the specific names *Blasdaleanum* and *Libocedri* for it see fit to retain their own name *aurantiacum*, although there is a *Gymnosporangium aurantiacum* of Chevallier⁴ published in 1826, seventy-eight years earlier.

As regards the standing of names applied to stages other than the teleutospore, it seems evident now that these authors will accept them in cases where there is no teleutospore name. A number of instances have already been cited in a foregoing paragraph. However, in previous parts it is not clear that they have been willing to do this; for example *Uromyces Silphii* Arth. founded on a specific name, which was originally applied to an æcidial stage, has been renamed *Uromyces Junci-tenuis* Syd. nov. nom.⁵

As already suggested, unusually full and accurate lists of synonyms have been included, but the arrangement of these is not always uniform or of such a nature as to make them most usable. It is not a straight chronological arrangement such as used by many authors, but the names are grouped according to the genera so that specific names belonging to the same genera come together. If the order of the

⁴ *Fl. Env. Paris*, 1: 424, 1826.

⁵ See Sydow Monog. Ured., Vol. II., fasc. II., p. 289, 1910.

³ *Hedwigia*, 37: 271-72, 1898.

names under a genus were chronological it would facilitate matters, and while it seems to be thus in many cases, it is by no means uniformly so. Under *Gymnosporangium clavariæforme* four synonyms in the genus *Æcidium* are cited, dated as follows, 1801, 1808, 1801 and 1905; four are also given here under *Roestelia* in this order, 1849, 1887, 1880, 1815.

In the matter of illustrations the present part shows a considerable improvement over the preceding parts. The drawings of the spores show more accuracy in preparation and do not look so diagrammatical. The fact that other structures aside from the teleutospores, such as peridial cells, have had representation in these illustrations is a matter worthy of favorable comment. The printing of the plates on the regular paper makes them somewhat difficult to find. Since not all species are illustrated it is not always possible to tell from the plate and figure number in which direction from the description one should turn to find the illustration. This could be avoided by including the page number of the plate (they all have page numbers although they are not printed upon them) along with the plate and figure number where the reference is given at the end of a description. It is also very difficult to find the description of a figure if one sees an illustration and desires to look it up. Aside from the figure number there might also be given the number of the page where the description occurs. These items would increase the amount of labor in preparation, but would enhance the value of the work sufficiently to warrant it.

The authors are to be praised for the great amount of valuable work they are doing with this difficult group of fungi, and mycologists in general must be exceedingly glad that the preparation of this large monograph has proceeded so steadily. With the appearance of the present part the larger and more important genera have received treatment. The world-wide treatment of such complex plants must necessarily entail an enormous amount of labor and must necessarily involve the inclusion of forms concerning which first-hand information may be meager. These authors

must be commended for the use which they make of the work of other specialists.

That they have drawn freely upon the observations of others is especially apparent in the arrangement of the keys, the form of descriptive accounts, the synonymy, and in the preparation of illustrations in this third volume. A deplorable feature is that the works of other writers and investigators may receive only slight or even no credit for the parts which are adopted by the authors or followed closely, whereas in minor portions, where there may be a difference of opinion they see fit to call attention to them in such a way as often to bring discredit upon the works which are really so largely utilized.

FRANK D. KERN

PENNSYLVANIA STATE COLLEGE,
STATE COLLEGE, PA.

The Primitive Family as an Educational Agency. By JAMES ARTHUR TODD. G. P. Putnam's Sons, New York and London, 1913.

"The Primitive Family as an Educational Agency" is frankly a brief against "the family superstition" in education, a brief, let one in turn be frank enough to say, that is hardly needed by the ethnologist and that will not be heeded, I venture to predict, by the sentimentalist.

To him or her Professor Todd has undertaken to show that the past of the family is not all it is supposed to be, that monogamy, for example, is an acquired predilection, that in primitive circles kinship may be an uncertain notion and that the "natural bond" between parent and child is merely a latter day figment.

So sympathetic am I with Professor Todd's main undertaking, the cornering of the sentimentalist, and so much in agreement with his general contention that non-familial agencies may have been or may become much more efficient in education than the family that I am reluctant to criticize his method and regret having to question several of his minor arguments.

As to his method, it may be enough to merely describe it as the method of illustra-

tion, a method apt to be as satisfactory to those with you as it is unconvincing to those against you. Professor Steinmetz has pointed out for all time that haphazard instances are not ethnological proof. The soundness of the comparative method rests on the scrupulous raking through of ethnographic data. Data assembled uncritically may also be misleading. Some of Professor Todd's illustrations are misleading. In citing modern Mexicans (p. 42), for example, he is not citing, as the text would convey, a primitive people. On pp. 39 ff. he confuses the grounds of divorce with the extent of it. In referring to the *pirravu* relationship of the Australian Blackfellow (p. 35) as an affair of intermittent promiscuity he appears ignorant of the fact that it is quite as stable a relationship and as carefully regulated as the coexistent pairing relationship.

Fortunately in spite of this misconception Professor Todd has not fallen into the old promiscuity pitfall. Still he argues that in view of well verified sporadic cases of group marriage and of periodic license monogamy is not an innate instinct. To this contention it may be said that group marriage is still too obscure a fact to be called upon with much assurance in argument. Whether periodic sex license may not be more adequately explained as a phenomenon of the breaking down of habit than of the persistence of an old habit is certainly an open question. As for other deviations from monogamy, polygyny, polyandry, and prostitution, are they not due to social processes which have rendered monogamy inadequate, to considerations of social prestige or dominion, to wealth or poverty, to ancestor worship? More social processes are involved in polygamy than in monogamy.

In education through the family does the form of marriage matter at any rate quite as much as Professor Todd together with his sentimental opponents would have us think? Until very recently purposive education in or out of the family has invariably taken the form of discipline, and in the polygynous patriarchal family there has ever been a greater degree of discipline for offspring than in any monogamous type of family. Then too

has not even brittleness in marriage been exaggerated as a pernicious effect upon offspring? Domestic education is essentially a matter of imitation, and one adult may be imitated as well as another. Family discord is of course pernicious, but brittleness in the marriage tie is likely to preclude discord, if anything.

But discipline is not education, I shall be told, nor is imitation. True, not in the modern meaning of the term education; but is that meaning to be reckoned with in considering any type of familial education as yet known? In all kinds of primitive education and in all kinds of familial education, primitive and modern, there has been but one purpose, the producing of conformity to type. If Professor Todd had taken this thesis as a basis for his arraignment of the rôle of the family in education, not merely pointing to it from time to time (pp. 146, 171), he would have been on safer and, I may say, more fertile ground. Moreover if he had stuck to the proposition he himself laid down at the outset that the bond between husband and wife or between parent and child is a primeval tropism based on the satisfactions resulting from safety and pleasure contacts he would have been under no necessity to show that monogamy was not an instinct, or that in view of the practise of adoption there was no natural bond in parenthood. Habitual association is the natural bond in parenthood whether adoptive or not. It is also the natural bond in marriage, whether brittle or lax. The pull of habit, whether in parentage or in marriage, Professor Todd together with many other students has overlooked.

Had he allowed for it, he would have escaped making several false generalizations. He would not have said that any sort of sex conduct was allowable among primitive men provided it did not infringe on the rights of others (p. 35)—unless of course he included among rights the right not to be discomfited by innovation, a right most jealously safeguarded by primitive man. He would not have argued that the family in which indefinite notions of kinship existed could not have exerted any great disciplinary force (p. 86).

(How about the coexistence of juridical parenthood and of discipline in the patriarchal family?) Nor would he have concluded that sex taboos, the demarcation of masculine and feminine interests, resulted in social discord (p. 54). He would have realized that sex taboos have quite the opposite effect, protecting the habits of one sex against the habits of the other. He might also have realized that age class similarly protects itself against age class and that respect for age is merely a survival of the rigid age class demarcations of primitive circles, in no sense a development (p. 131).

Until comparatively recently, "the formation of a body of habits," sex habits, age-class habits, family, clan or tribe habits was the goal of all education. As Professor Todd has well pointed out (pp. 143-4), primitive education planned to adjust youth to a static environment, to fit each boy and girl into a set place from whence no departure was possible, except into another set place. Modern education at its best plans to develop in all of us adjustability to a changing environment, together with a capacity to control our environment, *i. e.*, it plans to develop personality. To its part in this new venture of education the modern family is not yet awake. Hence its discredit in the eyes of Professor Todd and other modern educators. Once it realizes that of all educational agencies it has unique opportunities to develop personality, that far better than the school or the club it may lead a child to think for himself and to have the courage of a minority, once the family becomes alive to this new rôle—perhaps the coming "transcendent and valuable" rôle Professor Todd has in mind for it, it may assert with success its old claim to educational prestige—and not before.

ELSIE CLEWS PARSONS

NOTES ON THE SEA ELEPHANT
(*MIROUNGA LEONINA*)

MR. ROBERT CUSHMAN MURPHY has published in the *American Museum Bulletin*¹

¹ *Bull. Am. Mus. Nat. Hist.*, Vol. XXXIII., Art. II., pp. 63-79, pls. I.-VII.

an interesting and splendidly illustrated paper entitled "Notes on the Sea Elephant *Mirounga leonina*" (Linné). This article embodies the observations made by Mr. Murphy during a whaling and sealing voyage to the South Georgia Islands on the brig *Daisy* of New Bedford. Although sea elephants have been hunted for many years and thousands have been killed for commercial purposes, but little accurate information as to their life history is to be found in the literature of the species. This is perhaps partially due to the fact that their habitat lies on the desolate, storm-swept islands of the South Atlantic, in a region which holds out few inducements to the traveler and that almost the only visitors to their uninviting breeding grounds were those who came to slaughter the animals for commercial gain.

Too few of these hunters were interested in anything but the number of gallons of oil which could be tried out from each carcass, and ship after ship returned loaded to the gunwales with oil but empty of information concerning the habits of the greatest of all the seals which they were sweeping from off the earth. This relentless slaughter has long since passed the bounds of safety and the sea elephant bids fair to soon be numbered with the Steller's sea cow, an animal which has been swept away, leaving little but traditions behind.

Mr. Murphy's notes, taken with the care and interest of one who came to study and not to kill, are thus especially interesting, and combined with his splendid photographs form a valuable contribution to the life history of the elephant seal.

Dr. C. H. Townsend's rediscovery of the northern sea elephant (*Mirounga augustirostris*) on Guadaloupe Island, and the valuable collection of specimens and photographs which he secured, have done much to elucidate the life history of that species and Mr. Murphy has well supplemented his work by this study of the southern animal.

ROY CHAPMAN ANDREWS
AMERICAN MUSEUM OF NATURAL HISTORY

SPECIAL ARTICLES

CARDS AS PSYCHOLOGICAL APPARATUS

"THREE thousand dollars a year for a good instructor and one dollar for paper and pins" are considered a sufficient equipment for a fair elementary psychological laboratory by at least two distinguished American psychologists. The present paper is a brief account of some of the uses that may be made of paper in one form only, playing-cards, picture post-cards and library cards as found on the market. The uses described here relate to former work, to work now being done and to further possibilities.

In general, cards commend themselves as suitable experimental material on account of their cheapness, accessibility, generality, more or less familiarity and their standard nature in shape, size, weight and quality. The standard nature of the playing cards needs no qualification, and the variations of picture post-cards in shape, form, design, etc., are easily described and their pictorial features readily reproduced when necessary.

The frictionless or slipping quality of playing cards commends them for work requiring speed; they were first used in this connection by Jastrow¹ to determine the so-called discrimination (distinction) and choice time. And as a class demonstration of the time relations of these two mental processes the cards remain perhaps as simple and as cogent as any material now in use. Seven years later Professor Bergstrom² used "unprinted cards with the best slipping qualities" to study the resistance or interference offered by an old habit to the acquisition of a somewhat related one. He took advantage of the diminishing states of resistance to measure the rate of forgetting a habit. And further study has shown that an established habit may not simply interfere, but that it may also favor the acquisition of a new habit, *i. e.*, an old habit may blow both *cold* and *hot*, as it were, in its effect upon a learning process, and thus a study of the potency of one learning process upon

another is made possible by the use of cards. Coover and Angell³ determined the effect that skill in tossing colored cards into six small compartments bearing colored labels has upon the rate of manipulating the typewriter. In such experimentation playing-cards have proved exceptionally useful⁴ for the reason that the processes involved in their use are susceptible of analysis to the unitary stage. So that it becomes possible to make a quantitative estimate of the units of transference and interference.

The study of the "Learning Process" begun in this country by the original work of Bryan and Harter⁵ on "learning telegraphic language" inspired psychologists to draft the instruments of both work and play into the service of experimentation. The hand-ball and short-hand,⁶ the game of chess⁷ and the typewriter⁸ have each in turn made notable contributions to the learning process. But it is evident that neither these instruments nor their uses are adaptable to the laboratory as class apparatus. Economy of time alone forbids. Hand-balls are inexpensive, but ball-tossing as a learning process is narrow in its range and the operation too fantastic for laboratory purposes. There is need of simple ways and means whereby individuals of large classes may participate in the experimental operations. Among the more successful means now in use are nonsense syllables⁹ and the principle of reciprocal substitution of letters, figures and conventional symbols devised by Jastrow. We would add to the list the use of playing-cards *in connection with a distribution-case*. The case and its uses require a brief description.

We have found that a case 18 inches high, 36 inches long and 4 inches deep will furnish space for 54 compartments, having six in the vertical dimension and nine in the horizontal.

This arrangement furnishes a compartment for each card of the pack of fifty-two, and at the same time preserves an approach to equality between the dimensions without a large excess of compartments. Each compartment is three and a half inches in length by two and three fourths inches in height, and admits completely the average playing-card when *tossed*. Each compartment is provided with a metal clip for holding detachable labels cut from the cards.

Even one unacquainted with card games and card lore will realize upon slight reflection the well-nigh endless variety of combinations made possible by their qualities of form, color and number. The case is so labeled that the opportunity for forming associations between contiguous boxes and two or more successive distributions is rare. The cards may be unstacked or stacked, according to purpose. If the latter then learning the order of the cards affords a method for the study of serial learning. The compartments receiving the cards for any series are viewed only during the process of distribution, thereby creating conditions for the study of the sense of position. Perhaps we shall make better progress in suggesting the possibilities of problems and methods by briefly submitting a problem.

Let *A* distribute the pack according to number and color, throwing to the *diamond* and *club* compartments only. This requires 26 compartments, 13 of which receive the like numbered red cards and 13 the like numbered black cards. Let *B* distribute the pack to 26 compartments throwing to the red labels according to the following plan: Throw spades to hearts, and clubs to diamonds of the same number; *e. g.*, K and Q of Clubs would go to K and Q of diamonds, respectively, while the hearts and diamonds would be distributed to their respective compartments. We say they are "resident." *A* and *B* now practise for an equal time under uniform conditions until they can distribute the pack of 52 in about 55 seconds. They, then, exchange work and although the cards are stacked the same for both series, *A* manifestly will have to learn the location of 13 heart boxes and *B* 13 club boxes;

this in itself is a trifle, but it is coupled with the fact that the *directions* of the movements from box to box have made for each subject about 48, out of 52 possible, changes—a high percentage of motor interference. A further study of the consequences of the exchange of work shows that 25 per cent. of the sensory processes of the new work is identical with that of the old, while 75 per cent. is different and causes interference.¹⁰ If now the distributing practise be continued until the former speed is attained ample opportunity is given to study the operation and fate of transferable and interferable motor and sensory processes, respectively. And of course material is furnished for two "learning curves," one for the first and one for the second series. Doubtless several other problems solvable with this material and methods will occur to the psychologist. In this connection it may be stated that it has been demonstrated that the playing cards and the case constitute a psychotechnical instrument for scientific study of certain industrial operations. This has already been demonstrated by their application to the psychological problems involved in the distribution of mail to letter cases as done by post-office and railway-mail clerks.

Picture Postcards.—The value of pictures for *ausage*, memory and imaginative tests is now generally recognized together with possibilities for the study of the more intricate problems of feelings and attitudes. The technique and methods in these latter problems have not kept pace with those devised for the study of sensations and the will. The more complacent methods of introspection are to no purpose in the study of feelings and emotions since they do not come to order in the laboratory nor wait for introspective analysis; and the physiographic methods hitherto employed require considerable supplementing before the nature and relationships of the feeling consciousness are fully understood.

Some attempt has been made to use the reproductions of classic paintings in the study

¹⁰ For the basis and methods by which these quantities are determined see Kline and Owens, *Psych. Rev.*, Vol. 20, p. 224, 1913.

of feeling-tones only. And while such pictures are easily available their application is limited, for they are usually regarded by observers as pleasant or indifferent; seldom distinctly unpleasant. Their use is thus confined almost wholly in one direction, viz., that of esthetics. It is quite desirable to secure material capable of stimulating a wide range of feelings if we would make appreciable progress in their study. It appears that the advent of the picture postcards with their standard size, well-nigh endless variety and low price have more than supplied the experimental deficiencies of the classic pictures. The picture postcards make an appeal to the whole gamut of human affections. The technique for experimental purposes consists in selecting, adapting and in manipulating the cards so as to bring specific feelings into relief. To indicate uses as well as difficulties a few examples are submitted. The emotions that may be produced under laboratory conditions will always be rather feeble and so difficult to describe. The difficulty may be partially overcome by the use of picture postcards as material, some appropriate device for exposure and the law of dissociation as a method. According to James¹¹ the law of dissociation by varying concomitants holds for feelings as well as for sensations. The law states:

What is associated now with one thing and now with another tends to become dissociated from either, and to grow into an object of abstract contemplation.

By alternating one picture with various others it is possible to bring to notice obscure feeling responses that would otherwise go unreported, *e. g.*, if a picture of children at play is alternated with that of a beautiful woman; it is often hard for an observer to say anything further than that the pictures seem to go well together. But if the picture of a drunkard be substituted for that of the woman, not only does the disgust at the new combination serve for an interesting study, but the former feelings can now be more readily described.

¹¹ "Psychology, Briefer Course," p. 251.

We are thus furnished with a key to discover which feelings inhibit each other, which reinforce each other by contrast, and which fuse into one of a more general attitude. In short we are on the road to an analysis and synthesis of feelings.

The feelings aroused by the senses that respond to the stimuli of the outer or external world are usually objectified, *i. e.*, referred to the source of stimulation. For this reason observers are often at an utter loss to give an account of their attitude or to describe their feelings in response to a picture.¹² The psychologist's only refuge here is to call for repeated descriptions of the picture and to interpret the description in psychological terms. It is not difficult to devise conditions for readily repeating observations of the cards, and thereby enable the observer to carry the description a little farther each time. These descriptions, when carefully made, not only reveal the observers' feelings and attitudes but demonstrate the way in which apperception depends upon attitudes. These studies with the picture postcards have a practical bearing upon certain problems such as the order in which pictures should be hung in galleries, and the proper sequence and time exposure of lantern slides in illustrated lectures.

CHESTER E. KELLOGG

SOCIETIES AND ACADEMIES

THE ILLINOIS ACADEMY OF SCIENCE

THE seventh annual meeting of the Illinois Academy of Science was held in the engineering building of the Northwestern University, at Evanston, February 19 and 20, 1914, under the presidency of Frank W. DeWolf, director of the State Geological Survey. At the Friday session the following addresses were given:

"Recent Investigations of the Mineral Resources of the Country," by the president.

"Earth Tides," by Professor A. A. Michelson.

"The International Phytogeographical Excursion," by Professor H. C. Cowles.

"Recent Theories of Fertilization and Parthenogenesis," by Professor F. R. Lillie.

¹² G. Santayana, "The Sense of Beauty."

At 6:30 the members of the academy were entertained at dinner by Northwestern University. This was followed by a reception in the physical laboratory given by the local chapter of Sigma Xi.

At the Saturday meeting the following papers were presented by members of the academy:

"A Unified Science Course for High Schools," by Harold B. Shinn.

"Agricultural Science in the High Schools of Illinois," by A. W. Nolan.

"Reaction of Fishes to Temperature," by W. M. Wells.

"Soil Moisture and Plant Succession," by G. D. Fuller.

"The Vacuum Arc in Spectroscopy," by G. V. McCauley.

"Postglacial Biota of Glacial Lake Chicago," by F. C. Baker.

"Behavior Agreement Among the Animals of a Community," by V. E. Shelford.

"Evaporation and Soil Moisture in Forests and Cultivated Fields," by J. F. Groves.

"On Conditions Under Which the Vegetal Matter of the Coal Beds of Illinois Accumulated," by T. E. Savage.

"Comparative Analysis of Text-books of Zoology," by E. R. Downing.

"Recent Views Concerning Electrical Conduction in Solutions," by L. I. Shaw.

"Preliminary Note on the Cyclonic Distribution of Weather Elements for Davenport, Iowa," by A. D. Udden.

"Water Control at Evanston," by W. Lee Lewis.

At the business meeting it was decided to hold the next meeting at Springfield, February 18 and 19, 1915. The officers for the ensuing year are: *President*, Dr. A. R. Crook, Director State Museum, Springfield; *Vice-president*, Professor U. S. Grant, Northwestern University, Evanston; *Secretary*, Dr. E. N. Transeau, Eastern State Normal School, Charleston; *Treasurer*, Professor J. C. Hessler, Millikin University, Decatur.

EDGAR N. TRANSEAU,
Secretary

THE BIOLOGICAL SOCIETY OF WASHINGTON

The 519th meeting was held in the assembly hall of the Cosmos Club, January 10, 1914, with President Paul Bartsch in the chair. Five new members were elected. The discussion on parallel development was continued. L. Stejneger spoke

on parallelism as exhibited in reptiles, while Barton W. Evermann and Theodore Gill discussed it as related to fishes. Messrs. Eastman, Bartsch, A. D. Hopkins and William Palmer also took part in the discussion.

The 520th meeting was held January 24, 1914, with President Bartsch in the chair. Five persons were elected to membership. The program consisted of three communications:

"Winter Bird-life in the Swamps of Alabama," by E. G. Holt.

"Pollen Protection in the Flowers of *Acacia* and *Anona*," by W. E. Stafford.

"The Problem of the Gliding Gull," by William Palmer.

The 521st meeting was held February 7, 1914, President Bartsch in the chair. One new member was elected. Two communications were presented:

"Notes on the Fossil Mammals of the Fort Union," by J. W. Gidley.

"Certain Seeds Used for Ornamental Purposes in the West Indies," by J. N. Rose.

The 522d meeting was held February 21, 1914, Vice-president J. N. Rose in the chair.

The program consisted of three communications:

"Seasonal Movements of Fishes at Lake Maxinkuckee," by Barton W. Evermann.

"An American Swastika," by Henry Talbott.

"Surface Temperature in the Humboldt Current and its Coastal Eddies," by R. E. Coker.

The 523d meeting was held March 7, 1914, with Vice-president A. D. Hopkins in the chair. Three persons were elected to membership. The program consisted of two communications:

"Remains of a Prehistoric Feast," by William Palmer.

"Further Evidence of Mutation in *Oenothera*" (illustrated with lantern slides), by H. H. Bartlett.¹

The 524th meeting was held March 21, 1914, with President Bartsch in the chair. Two new members were elected. Two communications were presented:

"Arabic Interpretations of the Songs of Birds," by Paul B. Popenoe.

"Bird Migration in the Mackenzie Valley" (illustrated with lantern slides), by Wells W. Cooke.

"THE CAMERA OF QUALITY"

POLYGON CAMERAS

with

Rietzschel Double Anastigmats

are the embodiment of all that is desirable in cameras. They are compact, small, and light in weight, yet they are very reasonable in price: "They fit the Pocket." They are made from miniature size up to 5 x 7 inches, in all styles. All are built of light but indestructible metal; all are leather covered; all have leather bellows; all have rising, falling and cross front; all have detachable lensboard; all have quickly reversible ground glass; all are fitted with double anastigmats, the better ones with the finest cemented lenses ever put on the market, in compound shutter.

We also sell

ERNEMANN Cameras and Double Anastigmats

Third Edition, Rewritten

Whipple—

The Microscopy of Drinking Water

By GEORGE C. WHIPPLE, Gordon McKay Professor of Sanitary Engineering, Harvard University.

xxi+409 pages, 6 by 9, 73 figures and 6 plates in the text and 19 full-page plates in colors. Cloth, \$4.00 net.

This book serves as a guide to the water analysis and the water-works engineer, describing the methods of microscopical examination, assisting in the identification of the common microscopic organisms found in drinking water and interpreting the results in the light of environmental studies.

It is also the purpose of this book to stimulate a greater interest in the study of microscopic aquatic life and general limnology from the practical and economic standpoint.

PRINCIPLES OF CURRICULUM MAKING¹

THE favorite indoor sport of medical educators is curriculum making. As a game it ranks with jig-sawed pictures and "pigs in clover." It is not yet entirely clear whether this game should be played according to Hoyle or Marquis of Queensbury rules. The scores are published in our annual bulletins. Unfortunately no clear method of recording results has been devised. It is therefore hard to make comparisons, and no national champion has ever been declared. An expert can usually figure out the championship for any particular school. But the results would be much clearer if printed in some such form as this:

Professor Smith, Champion.... 964 hours.

Professor Jones, Runner-up... 807 hours.

Professor Brown, Booby prize. 24 hours.

It is evident that this game has interesting possibilities. Its serious discussion on this occasion may not be without value. Several of the schools of this Association have recently revised their curricula. Others are engaged just now in this work. These efforts are made necessary by a variety of conditions. In general it may be stated that dissatisfaction with the educational results obtained with existing courses of study is the principal cause of the desire for change. Furthermore, the new conditions brought about by increased entrance requirements make a readjustment of teaching desirable and perhaps imperative.

We Americans approach such a problem

¹ Presidential address at the meeting of the Association of American Medical Colleges, February 25, 1914.

with characteristic thoroughness. We are constitution makers by right of heredity. Our mechanical genius asserts itself. Our instinct is for standardization. We cut all our cogs to the same bevel. A rigid alignment of moving parts is insisted on. We are fond of link-belt machinery. We take advantage of gravity for feeding and screening. The machine runs well. The only trouble is that we forget the insignificant detail that we are making men instead of grinding corn.

A curriculum, gentlemen of the Association, is an important matter. Not so important as good individual teaching, it is true. Not so important, perhaps, as proper material equipment. Not so important as high ideals and a cooperative spirit among teachers. Nevertheless, curriculum making is a serious business. Are there no principles which may guide us in such an undertaking?

FORMER METHODS

The simplest way to form a curriculum is to have each professor state how much time he wants. This is doubtless the way the curriculum was made which every one was laughing at a few years ago and which required 230 hours of electro-therapeutics. The principle involved was "All cards have the same value. Every hand is a winner."

This method reaches its limit when the added demands of all the instructors make a larger sum of hours than the students can endure. As soon as this happened the usual procedure in the past was to place an arbitrary limit on total time requirements. Then each professor began to fight for as large a share of this time as he was able to obtain. This was probably the way in which a certain curriculum was produced containing 1,300 hours of anatomy.

The principle was "Jack-high and a pistol take the pot."

These simple methods and elemental principles may have been adequate in ruder, simpler conditions. The best time-getter was often the best teacher. At least he was a strong personality. No standards existed. No state boards had formulated embarrassing exactions. The student considered one school as good as another; or, most likely, he believed the particular school he was attending to be the only good school. He was concerned with a certain square of parchment to be obtained after so many years and for the payment of so many dollars. He was not expected to think and succeeded in meeting all expectations.

THE FREE ELECTIVE SYSTEM

The opposite of these primitive methods of curriculum-making is the free elective plan. This has never been tried out in medical education. But Harvard College had a long experience with a program in which very little restriction was placed upon the students' choice of teachers and subjects. Many western universities gave equal or greater liberty to their students. It could almost be said that there was no curriculum. The principle was "American plan hotel. Everything on the table. You pay your money, and you take your choice."

The results were excellent for serious students of good judgment. But many men are not serious, and not all serious men have good judgment. A goodly proportion of men were found to be selecting their courses so as to fit in well with midnight suppers and late breakfasts and afternoon teas, or with more questionable employments. The snap course was the college man's blessing. Men were graduated whose education was an imitation veneer on a pasteboard background. As a

consequence all the colleges, I believe, have had to limit the freedom of election in a marked degree. The group system by which the student is compelled to do a considerable part of his work in one department or group of allied departments has been widely adopted. The principle is "A thorough training in a definite direction."

Of course the curriculum of a professional school is a group curriculum by the nature of things. The question is whether it shall be fixed and inflexible or variable and elastic.

GENERAL PURPOSES

Now it is evident that if we are to make any serious effort to find guidance in our own experiments in curriculum-building, we should begin by determining as well as possible what we are trying to do. It is easy to say that our first business is to make doctors—to make good doctors. But a "good doctor" is hard to know and harder still to define. I have discussed this matter before² and will only recapitulate my conclusions here.

A good doctor is a keen observer. We must train the powers of observation in our students. We may say that there is a technique of observing, and that we must teach this technique.

A good doctor is a trained experimenter. That is, he combines control of conditions with observation. We must train our students in experimental methods in the laboratory and at the bedside. This is technical training.

A good doctor is a skilled technician also in another and narrower sense of the word. He knows how to do certain things connected with the practise of his profession, things requiring accuracy of hand, ear

and eye. He has attained a skilful adjustment of certain senso-motor reactions not provided by nor required in the ordinary experiences of life, but essential in medical practise. Such adjustment is attained only by repetition under direction; that is, by development of habit. We must train our students in the technique of their profession.

A good doctor is a man of judgment. He must be able to draw correct conclusions from observations and experiments. He must be able to synthesize isolated elemental facts into a unified compound. We express this idea when we say he must be able to think. And here is the greatest stumbling block. No one has discovered a royal road to thought. It almost seems as if it is in a man or it isn't. And yet thinking is really a kind of technique. It consists in making valuable associations. If you have on hand the proper thought-stuff and can make the right combinations of it—why, you think. Given a particular sensory stimulus, the resulting impulses presumably go bounding from part to part of the cerebral cortex instead of coming out immediately to the muscles. How these impulses travel depends on how the cerebrum is constructed and which paths have been made easy. Thought in this sense is involuntary response; it is reflex, it is habit.

A large part of our teaching is devoted to giving students what we consider valuable thought-stuff—facts, we call it. We also give them numerous examples of thinking—ready-made combinations of facts, or so-called conclusions. This is well. It ought to help them in the same way that seeing a blacksmith forge out a tool should help one to make that tool, or in the same way that seeing a surgical operation should help the student to do it. But when it comes to making new thoughts, the only

² *American Medical Association Bulletin*, January 15, 1911; also "Medical Research and Education," *Science Press* (1913), p. 375.

way is by practise and repetition and habit. We can help another man's thinking chiefly in the same way that we can help his drawing or his chemical analysis or his physical examination, by stimulating his interest, by showing him where he fails and by teaching him to criticize his own work, as he would any other technical achievement.

Finally, the good doctor is a man of character, which means again, I suspect, only that he has on hand certain kinds of brain-stuff, makes certain kinds of associations of it and reacts in certain ways to these associations. Here again example and criticism are the basis of teaching. A good doctor is skilled in the technique of right behavior. He makes mistakes in ethics no more than in counting blood corpuscles.

You will all see that I have used the word "technique" in a broad way. Probably I have stretched it too far. But for to-day we will let it stand and will ask ourselves what principles should guide us in attempting to make this kind of technicians out of the young men who come to us as students.

Putting the matter in another way, our purpose is to train scientific physicians. By a scientific physician I mean one who is imbued with the principles of science and trained in particular scientific methods. I do not mean that he should necessarily be an original investigator. I do mean that he should approach his work in the spirit of an investigator.

Our commonest stumbling block in considering a problem in curriculum making or in teaching is the unfortunate belief that we must turn out our graduates as fully trained doctors. "There is so much that they need to know," we say. This idea leads us to overcrowd the curriculum and deprive it of elasticity and vitality. Our aim should be not to turn out a finished doctor, but a man who will continue to

work and learn as long as he lives—a man who will consider that his student life has just begun on the day when he takes his diploma. Our aim should be not to produce a walking encyclopedia, but to inculcate the scientific spirit. What principles are likely to be of service in this work?

ENTRANCE REQUIREMENTS

Of course the first principle is that we start with good material. We depend upon certain "entrance requirements" to supply this material. We can not stop to consider these requirements to-day, except to remark their mechanical character. A sieve is a good instrument for separating different sizes of coal. It is a bad instrument for separating pebbles from diamonds. The best formulated entrance requirements will supply good material only when supplemented by personal consideration of the individual case. Often you can only tell the diamond by seeing whether it will scratch glass. My sentiment is that it is better to try out ten pebbles which will fail rather than risk throwing one diamond into the dump.

PRINCIPLE OF INDIVIDUAL DIFFERENCES

Having selected our students, we must recognize the inequality among them. No two freshmen are alike. No two seniors are alike. No two graduates are alike. No two old doctors are alike. We are all "born short" in one place, "born long" in another, to use William Hawley Smith's³

³ "All the Children of All the People," Macmillan, 1912. Mr. Smith discusses also the similarities of children. Of course the principle of similarities is basic in any system of education. The trouble in medical education is that we have assumed not only similarity but even *equality* among students. This address is a protest against the prevailing rigid curricula and emphasizes therefore the differences of students, to the present disregard of their similarities. The latter

expressive metaphor. The recognition of the principle of inequality is a most important step in curriculum making. Everything else really rests upon it. If we had a magic yard-stick by which to measure each man's powers and lay out the curriculum adapted to develop those powers, it would be our duty to do so. Education would then become truly individualistic. Since we can not accomplish this ideal, we must do our best to approach it. We know that no body of men is able to lay out a perfect curriculum for medical students taken in the average or *en masse*; witness the severe criticism which may be laid against the A. M. A. model, founded though it was on two years' work by a committee of a hundred medical educators. Recognizing the principle of inequality of men, how much less can any faculty work out a fixed curriculum adapted to the student considered as an individual. To my mind the argument leads inevitably to the elastic curriculum. An elastic curriculum is not an elective curriculum, although the elective principle should find recognition in it.

PRINCIPLE OF RELATIVE VALUES

We have said that our aim is to develop technicians and that for this we must furnish facts on which the thing to be done, whether of hand or brain, is founded. In furnishing these facts, the important principle of relative values must receive emphasis. It is a fact that the stomach secretes a

principle will take care of itself in any group curriculum, for as Professor Jackson has said: "Our medical students represent a selected group whose physical and mental characters are, broadly speaking, quite similar. This is tacitly assumed in making fixed requirements for the greater part of the curriculum. Yet the individual differences are undoubtedly of tremendous importance, and have hitherto been largely overlooked in medical education."

certain per cent. of hydrochloric acid. It is a fact that the lachrymal glands secrete a certain per cent. of sodium chloride. The former fact is much more valuable to a physician than the latter. It is valuable practically. Many other facts not immediately valuable in treating patients are valuable practically as thought-stuff. Facts are like medicines; some are for external and some for internal use. But the differences among facts as regards usefulness are as great as the differences among medicines. We should do our best from the multiplicity of facts to supply those most likely to be valuable to our students. Now the pie-maker is not a good judge of the value of pie as an article of diet, nor is the specialist in all respects in the best position to evaluate relatively his line of facts. The physiologist should have the help of the internist, the aurist, the oculist and the neurologist in determining what facts of physiology should be taught and the time to be devoted to this teaching. The principle applies equally to all the other teachers and their branches of knowledge.

PRINCIPLE OF MINIMUM REQUIREMENT

This leads to the principle of minimum requirement. Take anatomy, for example. We will all admit that certain facts of structure of the body form an indispensable part of a medical man's equipment. A knowledge of these facts must be demanded from every student. This minimum is hard to set—impossible, indeed, in a strict sense. Still, for practical purposes it must be set. In my judgment the minimum in nearly every subject is much less than schools have ordinarily required. They have required as much as possible, not as little as possible. In my opinion an effort should be made in each department to ascertain the minimum. This should be taught intensively. The merely desirable,

the questionable and the specialistic material should go into elective courses.

In formulating its minimum a department should bear in mind that not all the teaching of its subject-matter is done by itself. Anatomy is taught—should be and must be taught—by surgery and pathology; physiology, by medicine and pharmacology, and so on.

The sum total of these minima should constitute the required part of the curriculum. Probably they should make up between three fourths and seven eighths of the total. Nobody really knows.

PRINCIPLE OF SEQUENCE

In arranging a curriculum the principle of sequence must be kept in mind. Certain subjects are indispensable prerequisites to another subject. Others are desirable prerequisites. While this is true, it is also undoubted that this principle may be carried too far. The subject-matter of medicine is inextricably woven together. It is not even separable from the great body of general science. Our departments are in a measure artificial and arbitrary divisions. If a man goes into physiology before he has had anatomy, he is handicapped, it is true. But, on the other hand, when he gets to anatomy after physiology, he will carry to that work usable facts and enlarged interest. We may acknowledge that systematic knowledge of disease is valuable before the student can take up clinical work to best advantage, and consequently we make didactic courses prerequisite to clinics. But consider for a moment how much more intelligently the student would approach a systematic lecture course if he had previously seen some sick people. We should not allow too rigid an application of sequence to interfere with larger aims of elasticity and the recognition of individual capability and needs.

PRINCIPLE OF CONCENTRATION

In making a curriculum the principle of concentration deserves consideration. The theory is that the student does better work if he confines himself to one or a few subjects for a given short period of time. He is to concentrate on one thing and get it done. The antagonistic view is that the student gathers more from a subject kept before him for a long time. Under this theory the curriculum may include from six to a dozen subjects running through a semester or a year. Recently I met a freshman in the college of science, literature and the arts of our university who was studying seven subjects. She complained of being harried and overworked. I believe she would do better with the same number of class hours devoted to only three or four subjects. I think we should avoid the multiplicity of subjects in the junior and senior years by concentrating one hour a week lecture courses so as to run a shorter time and more periods a week. On the other hand, I can not bring myself to accept the Harvard plan by which only anatomy is studied the first semester, only physiology the second, and so on. I think Harvard has stuck to this plan more for the benefit of the teachers, who thus escape class work half of each year, than for the benefit of the students. Be that as it may, too much concentration is bad pedagogy; and in as much as it contributes to a rigid curriculum, it is a bad principle of curriculum making. A proper medium is to be sought between concentration to the crystallization point and dilution to tastelessness. At the present time we are more guilty in the latter direction, particularly as regards the rapid shifting of students among clinical instructors. If Dr. A. meets a group of students to-day and does not see them again for six weeks, how is Dr. A. to make his personal-

ity felt in these students' training? Dr. A.'s influence is lost in homeopathic dilution, which we should be ashamed to countenance.

The proper degree of concentration needed to produce best results should be possible of determination by the methods of experimental psychology. I understand that something has been accomplished in this line, particularly as regards memory. It is a common impression that "cramming" does not conduce to permanent acquisition. This conclusion is supported by laboratory tests. On the other hand, experiments prove that a subject referred to only at long intervals is not well remembered. There must be a golden mean between concentration and dilution. For this golden mean we should earnestly strive, and the psychologists should help us to find it.

PRINCIPLE OF ATTENTION AND INTEREST

Taking up more particularly the individual student in curriculum making and teaching, we should take into account the element of interest. A girl can dance all night with the pleasurable expenditure of several foot-tons of energy (no pun intended). Her back aches if she sweeps the floor, though the muscular energy discharged be insignificant. We should avoid a multiplicity of detailed laboratory exercises illustrating the same thing. The humdrum of laboratory repetition kills interest and initiative. Recognition of the principle of interest means an elastic curriculum, for the interest of one student is not the same as the interest of another student.

Interest is the basis of attention and of that self-activity which Dr. Jackson⁴ so

well discussed before this association two years ago. So important is this element in education that almost any sacrifice is warranted which will attain it. In our sophomore schedule at Minnesota this semester there is provision for six hours of elective work. It has been our custom in the case of conditioned or backward students to compel them to carry the required courses and postpone their electives. The other day a student appeared before the conference committee of the faculty and made a strong plea to be permitted to carry his elective. He said he was interested in that work and would rather postpone one of his regular studies. The committee voted favorably on his request; and in my opinion they acted wisely, for his failure to work with serious effort heretofore has been due to lack of interest. I expect him soon to observe that this elective work in which he is now interested is really tied up with all the rest. I expect to see his interests broaden and all of his work improve.

PRINCIPLE OF RESPONSIBILITY

Closely related is the principle of student responsibility. We are interested in work for which we are responsible. This is especially true if we select the work ourselves. A fixed curriculum deprives the student of all responsibility. He becomes a boarder coming in to meals when the bell rings, not a man laboring for his daily bread. If he may choose his subject or his instructor, his interest and responsibility increase.

Workers in the field of animal psychology tell us that animals carried through a maze never learn how to find their way alone. Let us remember this when tempted to help students over difficulties. Our teaching and our courses of study must be so planned as to encourage initiative and responsibility.

⁴ C. M. Jackson: "On the Improvement of Medical Teaching," *SCIENCE*, N. S., Vol. XXXV., p. 566 (1912). Also, "Medical Research and Education," *Science Press* (1913), p. 367.

PRINCIPLE OF RESEARCH

The principle of research is very important in curriculum building. I do not advocate research with the idea that we should announce a great discovery every few minutes. I advocate it as supplying the proper atmosphere for teaching. The fixed curriculum segregates a certain portion of knowledge and teaches it as law and gospel. The student is like a red corpuscle confined by the vessel walls to a definite circuit. If the teacher has research interests, he carries them alone. His students can not follow him. The elastic curriculum permits the capable student to put out an occasional pseudopod and make little excursions with his teacher into the unknown. This can not help but react upon both student and teacher; and most important of all, on the spirit of the school. If time and opportunity for research are to be offered even to the exceptional student, it means that the electives can not be confined to the last year, as at Harvard, nor to one semester, as in some other schools. The free time should be scattered through the course, at least beginning with the sophomore year. I sometimes hear that the sophomore does not know enough to select any of his work. I can not agree. The sophomore in most of our medical schools is a junior or senior in the college of arts. He is a university man. He should be responsible. He should be thinking about what he is doing. The nursing bottle should be taken away, and he should choose and masticate his own food. Not many will nibble at research, but the aroma of it may well permeate the whole pantry. It will improve the taste of all the other food.

PRINCIPLE OF SPECIALIZATION

The principle of specialization may be given some attention. While every medical student should have the fundamental

training of a general practitioner and while most of the elective courses will naturally be adapted to strengthen the student's general grasp, there is no objection, in my opinion, to a moderate extension of specialistic instruction. There are very few students who would care to move far along a specialty in their undergraduate course, and the dean or students' work committee should have power to prevent an abuse of this principle by limiting election in the specialties when such election would be likely to prejudice a student's general training.

PRINCIPLE OF UNEQUAL PROGRESS

Finally, regard for the differences and inequalities among students should make us consider their inequality of progress: the principle of unequal velocity, if you will. Some students by physical constitution and mental make-up are calculated to go forward more rapidly than others, who, being built on the "slow and careful" plan, may in the end be just as good doctors. Our arrangement of students into definite classes and a four years' required attendance is the worst possible condition for the extra bright man, whom it tempts to laziness, and for the slow man, whom it pushes beyond his powers. In my opinion students should be received at any time when a workable program can be arranged for them, and graduated at the end of any semester or summer term when they may have completed the requirements. Our extra intern year at Minnesota, as part of the requirement for the degree and consequently of attendance, will, I think, allow us to work this plan without running counter to the four-year rule of the state laws. The class system is a pernicious artificiality in education and should be done away with in professional education, if not more widely. So should the four-months' required vaca-

tion. The doctor-in-practise works eleven months or more. Why should the doctor-making work only eight or nine? Some students may need the long vacation for health's sake; others may need it for financial reasons. But some would be better off without the long interruption of their studies. Moreover, important elements of economy argue for the continuous session and a curriculum adapted thereto. Our expensive equipments stand idle one third of the time. Our hospitals and dispensaries go on the year around and are unused for teaching for several months. This would be poor practise in any line of business. For our northern schools, at least, the University of Chicago idea with its four quarters and its liberal curriculum, appeals to me as eminently wise. The next best thing is a strong summer term for which credit⁵ is given on the regular course.

Your professors may say that they can not teach the year around. Well and good. They ought not to. While some of the older men should be "on the job" during the summer and may arrange their vacations at some other season, on the whole the summer quarter or term is a good time to give the younger men a chance. Let them conduct courses given at other times by full professors. A repetition of courses, at least in certain subjects, has advantages and is essential if a really elastic curriculum is to be developed.

CURRICULUM MAKING FROM THE SIDE OF THE TEACHER

I have gradually swung this discussion over from the side of the student to that of the teacher. Several principles of curriculum making may be formulated from the side of the faculty.

⁵ The distinction between subject credit and time credit is not sufficiently recognized by medical educators. It is only time credit which is restricted by the state medical laws.

THE DEVELOPMENT OF TEACHERS

One of these principles is the development of the teacher. The rigid curriculum works but little for this cause. A professor of principles of surgery, for example, lectures year after year on that subject. For years perhaps the same manuscript is read to the classes. There is no incentive for a younger man to prepare himself. Finally, the old professor drops away, and a new and untried man must take his place. An elastic curriculum with repetition of the course under various instructors means the opportunity for the development of new men all the time. The prepared man is ready for the advanced position.

PRINCIPLE OF COMPETITION

The principle of competition is as important for efficient teaching as for any other trade or business. The rigid curriculum tends to develop a trust in teaching, with the usual bad characteristics of trusts. The elective system by giving the student a choice among several men furnishes each teacher with incentives to bring his work to the highest state of efficiency. The experience of Rush Medical College in this regard has been very instructive.

It might be thought that students would abuse this privilege of electing their instructors and that the easiest teacher would be most popular. That has not been the case. The students can be trusted to go where they get what they consider the best for themselves. Their judgment, on the whole, can be trusted. A general rule requiring approval of electives by the dean or a committee is a sufficient safeguard against the few who might search for "snap" courses.

The elective system tends to make a larger number of men available and useful as instructors and a larger number of hospitals available and usable for clinical in-

struction. So long as every student must appear before every instructor we have the tendency either unduly to reduce the number of instructors or unduly to reduce the time the individual instructor teaches. Either horn of the dilemma is dangerous. To be effective, clinical teaching must approach the ideal of individual teaching. Not how many students an instructor teaches, but how well he instructs a limited number, should be the criterion of his usefulness to a school and of his own sense of satisfaction with his work. As I have said earlier, nothing is worse than a whirlwind program which sends the students in vortices of section instruction so rapidly from teacher to teacher that no one can impress his personality upon the students. The belief that every teacher must teach every student, long since given up in colleges of arts and sciences, is pernicious and inexcusable. If your ideal of teaching is merely to reach as large a number of prospective consultants as possible, stop teaching and buy stock in a patent medicine company.

THE CURRICULUM AND THE DEPARTMENTS

As regards whole departments of instruction as distinguished from individual instructors, certain principles of curriculum making may be mentioned. A proper regard for the "born long" and "born short" demands greater elasticity in departmental procedure than is usually the case in our American schools. There should be better provision for the irregular student. Opportunities for laboratory work should be afforded at other than scheduled hours. Men should be encouraged to work alone or with a minimum of supervision. Let us limber up our laboratory organizations. Let our motto be salvation by individual work rather than salvation by formal creed. "Laboratory" should be synony-

mous with "Opportunity" not with "Drudgery."

The offering of electives is one important means of liberalizing a department. This system allows the instructor to vary at least a part of his work from year to year. It enables him to teach to the interested few those subjects in which he is immediately interested. It diminishes the temptation to introduce the instructor's fads as part of his required courses. It broadens the interests of a department by giving scope for all its members.

The elective system allows the young instructor who is assisting in a large required course to gain independence and confidence by conducting a small elective course in his special line. This is important.

THE CURRICULUM AND THE SCHOOL AS A WHOLE

Now as regards the school as a whole, certain principles of curriculum making may be formulated. It goes without saying that conditions as regards the quality of instructors, students and material facilities must vary among institutions. They ought not to adopt identical curricula.⁶ The American Medical Association and Association of American Medical Colleges have presented models which are very valuable as points of departure. A curriculum committee should consult other schools, but not with the purpose of adopting their curricula unchanged. Each school should work out its curriculum with broad wisdom to suit its own conditions. It would be worse than folly, for example, if small and weak schools should attempt a wholesale adoption of the elective work which I so strongly

⁶ While this statement is true, it may also be stated that important advantages would follow a substantial agreement among the schools as to the minimum requirements in each branch. For one thing, migration of students, at present very difficult, would be facilitated.

advocate. It would be folly even for a strong school to push this principle equally in all departments. A curriculum is a road or a race track. Road materials are quite different in central Illinois from those which abound in New England. Bear this crude analogy in mind.

The school revising its curriculum should avoid all possibility of allowing this important function to deteriorate into a contest for teaching time. Such a procedure loses sight of the principles involved and the objects to be sought. Consequently, curriculum revision must be approached with care and carried forward with tact and open-mindedness. Our recent experience at Minnesota is perhaps illuminating. The committee on revision was composed of three men only. These men studied conditions thoroughly and were able to speak with authority concerning conditions in our school and elsewhere. They studied the educational and pedagogical problems involved. This committee did not overwhelm the faculty by bringing in a complete report at one time. It first secured the approval of the faculty for certain general principles such as (a) "The necessity of limiting the scheduled work to about thirty hours a week or about 4,000 hours for the course." (b) "The necessity of clinic clerkships as a required part of the senior schedule." (c) "The desirability of elasticity to meet individual preparation, abilities and needs of students." The individual members of the faculty, recognizing the validity of these educational policies, approached the proposal to decrease their hours in excellent spirit. Consultations of departments with the curriculum committee led to practical unanimity of opinion on details; and when the final report was presented to the faculty, approval was quickly secured.

Gentlemen of the association, you have listened well. Probably you got into the

habit when you sat upon the benches as medical students. Probably, like the students of this day, of whom we are dealing, you learned to "let it go in at one ear and out at the other." Is our lamentable ability to hear and forget due to something like interference of sound, some mental process by which the impressions from one ear annihilate those from the other? Or is it rather true that we are only to be jarred from our complacent forgetfulness, our nonchalant do-nothingness, by something unusual? I think the latter, at any rate, is a fact; and I am going to risk the dignity of the presidency and hang the moral of my previous remarks on some lines copied from the back of a seat in the amphitheater of one of our medical schools, where they had been scratched in the varnish by some medical student, departed and forgotten:

Talk, Talk, Talk,
Till my ears are split by the din.
Sit, Sit, Sit,
Till my pelvis sticks through the skin.
In clinic and lecture and quiz
I wear out my pants to the seam,
Till over the benches I fall asleep
And wear 'em out in my dream.

You laugh! But really are not these doggerel verses as pregnant with pity as the "Song of the Shirt"? Are they not as full of meaning for us as were the words of Hood for callous wealth and heedless government in poverty-stricken London?

The plaint of the student we have heard before, delivered in more dignified but less expressive form by speakers on this floor. Our students are overcrowded. They have no time to think. They do not think. Their individual qualities are crushed. They are made to conform to a common mould. The curriculum is largely responsible. We are responsible for the curriculum.

We make the usual specious arguments. The students are poorly prepared. The time of the course is too short. There is so

much to teach. Medicine is going forward so fast.

Let us broaden our conception of medical education by broadening our conception of education itself. Education is primarily the bringing out of something from within, not the forcing of something in from without. It is the discovery of the individual to himself. It is a process of training, not a process of fattening.

If these conceptions of education gain possession of us, we shall approach our teaching and our curriculum making in a corresponding spirit, and some at least of the difficulties and disappointments of our labor will disappear.

E. P. LYON

MEDICAL SCHOOL OF THE
UNIVERSITY OF MINNESOTA

INDUSTRIAL FELLOWSHIPS OF THE MELLON INSTITUTE¹

SINCE January, 1912, I have made no report to this journal on the progress in the system of industrial fellowships initiated by me at the University of Kansas and since transferred to the University of Pittsburgh.

The working of these fellowships began September 1, 1911, on the university campus at Pittsburgh and in the temporary building erected at a cost of about \$10,000. In March, 1913, Mr. Andrew William Mellon and Mr. Richard Beatty Mellon, brothers and citizens of Pittsburgh, impressed by the evident practical value of this system both to learning and to industry, established it on a permanent basis through the gift of over half a million dollars and consented to allow their family name to be placed upon it as the "Mellon Institute of Industrial Research and School of Specific Industries of the University of Pittsburgh." While working in affiliation with the university and in close sympathetic accord with it, the institute is possessed of its own funds and is under its own management.

¹ This article was written by Dr. Duncan shortly before his death.

The gift of the Messrs. Mellon has been divided for expenditure as follows:

FOR IMMEDIATE EXPENDITURE:

Permanent building	\$250,000
Apparatus	60,000
Library	20,000

FOR YEARLY MAINTENANCE FOR FIVE YEARS:

\$40,000 per year.

Since September, 1911, the following Fellowships have been established and in operation:

1. BAKING:*2

\$750 a year for 2 years.

Bonus, maximum cash: \$2,000.

Fellow:

Wilber A. Hobbs, B.S. (University of Kansas).
(Accepted November 30, 1910.)

2. ABATEMENT OF SMOKE NUISANCE:

\$12,000 1st year; \$15,000 2d year; \$12,000 3d year.

Fellows:

Staff in Charge

R. C. Benner, Ph.D. (University of Wisconsin),
chief fellow first and second years.

J. J. O'Connor, Jr., A.B. (University of Pittsburgh), economist and chief fellow third year.

W. W. Strong, Ph.D. (Johns Hopkins), physicist.

A. F. Nesbit, B.S. (Massachusetts Institute of Technology), electrical engineer.

J. A. Beck, LL.B. (University of Pittsburgh), attorney.

E. H. McClelland, Ph.B. (Lafayette), bibliographer.

O. R. McBride, B.S. (Purdue University), engineer.

J. E. W. Wallin, Ph.D. (Yale University), psychologist.

H. H. Kimball, Ph.D. (George Washington University), meteorologist.

A. B. Bellows, B.S. (Massachusetts Institute of Technology), engineer.

J. F. Clevenger, M.S. (Ohio State University), botanist.

C. H. Marcy, bacteriologist.

Advisory Staff

Oskar Klotz, M.D., C.M. (McGill University), senior fellow.

* 2 means that the fellowship has expired.

E. W. Day, A.M., M.D. (Georgetown).
 W. C. White, M.D. (Toronto).
 R. T. Miller, Jr., M.D. (Johns Hopkins).
 W. W. Blair, M.D. (Hahnemann).
 B. A. Cohoe, A.B., M.D. (Toronto).
 S. R. Haythorn, M.D. (Michigan).
 W. L. Holman, M.D. (McGill).
 E. B. Lee, architect, senior fellow.
 Richard Hooker, B.S., architect.
 C. T. Ingham, architect.
 Richard Kiehnel, architect.
 Carlton Strong, architect.
 K. K. Stevens, B.S., architect.

(November 30, 1910; revised June 24, 1911.)

3. ON THE RELATION OF THE POTS TO GLASS IN GLASS-MAKING AND THE ELIMINATION OF "STREA":*

\$1,500 a year for 2 years.

Bonus: \$2,500.

Fellow:

Samuel R. Scholes, Ph.D. (Yale University).
 (January 25, 1911.)

4. BAKING:*

(Wholly independent of but with acquiescence of No. 1.)

\$4,750 a year for 2 years.

Bonus, cash: \$10,000.

Fellows:

Henry A. Kohman, Ph.D. (University of Kansas), senior fellow.
 Charles Hoffman, Ph.D. (Yale University).
 Alfred E. Blake, A.B. (New Hampshire College).
 (January 25, 1911.)

5. GLUE:

\$1,200 a year for 2 years.

Fellow:

Ralph C. Shuey, B.S. (University of Kansas).
 (February 3, 1911.)

6. SOAP:

\$1,200 a year for 2 years.

Fellow:

Paul R. Parmelee, B.S. (University of Kansas).
 (February 3, 1911.)

7. UTILIZATION OF FRUIT WASTE:*

\$1,000 a year for 2 years.

Bonus: \$10,000.

Fellow:

F. Alexander McDermott (George Washington University).
 (May 12, 1911.)

8. COMPOSITION FLOORING:*

\$1,500 a year for 2 years.

Bonus: 1 per cent. of sales for 5 years.

Fellow:

R. Rex Shively, B.S. (Oklahoma A. and M. College).
 (August 15, 1911.)

9. CRUDE PETROLEUM:

\$10,000 first year; \$10,000 second year; \$10,000 third year, including apparatus fund.

Bonus: Collective interest 10 per cent.

Fellows:

Benjamin T. Brooks, Ph.D. (University of Göttingen), senior fellow.
 Clinton W. Clark, M.A. (Ohio State University).
 Lester Pratt, M.S. (New Hampshire College).
 Hugh Clark, M.A. (Ohio State University).
 Arthur H. Myer, A.M. (Leland Stanford Jr. University).
 Frederick Padgett, B.S. (University of Pittsburgh).
 F. W. Bushong, Sc.D. (Emporia College).
 I. W. Humphrey, B.S. (University of Kansas).
 George W. Stratton, Ph.D. (Ohio State University).
 (September 22, 1911.)

10. NATURAL GAS:

\$4,000 first year; \$4,000 second year; \$6,000 third year, including apparatus fund.

Bonus: 5 per cent. industrial results.

Fellows:

R. H. Brownlee, Ph.D. (University of Chicago), senior fellow.
 Roy H. Uhlinger, M.A. (University of Pittsburgh).
 (September 22, 1911.)

11. CEMENT:*

\$1,800 a year for 2 years.

Bonus: \$10,000.

Fellow:

J. F. MacKey, Ph.D. (University of Toronto).
 (September 22, 1911.)

12. FOODS, PROBLEMS RELATED TO THE MANUFACTURE OF:

\$5,000 a year for 2 years.

Bonus: \$10,000.

Fellows:

Clarence C. Vogt, Ph.D. (Ohio State University), senior fellow.

Harry P. Corliss, Ph.D. (University of Pittsburgh).

Mrs. Lou H. M. Vogt, Ph.D. (Ohio State University).

(May 20, 1912.)

13. FATS AND OILS, BLEACHING OF:

\$1,500 a year for 2 years + \$300 apparatus fund.

Fellow:

Leonard M. Liddle, Ph.D. (Yale University).

(May 22, 1912.)

14. EFFECT OF HIGH POTENTIAL ELECTRICITY ON CHEMICAL REACTION:

\$1,000 a year for 2 years + \$300 apparatus fund.
Additional consideration.

Fellow:

W. E. Vawter, B.S. (University of Kansas).

(October 28, 1912.)

15. DISCOVERY OF METHODS OF COATING STEEL OR OTHER METALS WITH COPPER OR OTHER METALS:

\$1,500 a year for 1 year + \$500 apparatus fund;
3 months' extension.

Bonus: \$10,000.

Fellow:

C. L. Perkins, B.S. (New Hampshire College).

(December 4, 1912.)

16. EXTRACTION OF COPPER FROM ITS ORES AND FROM COPPER "TAILINGS":*

\$1,500 a year for 1 year.

Teaching Fellow:

Howard D. Clayton, B.A. (Ohio State University).

(December 1, 1912.)

17. DESERT PLANT AND ADDITIONAL PROBLEM:

\$1,500 a year for 1 year + \$300 apparatus fund.
Bonus: 7 per cent. interest industrial results.

Fellows:

R. R. Shively, Ph.D. (University of Pittsburgh).

Alfred E. Blake, M.S. (University of Pittsburgh).

(January 31, 1913.)

18. BAKING:

\$6,000 a year for 2 years + \$500 apparatus fund.

Bonus: \$10,000.

Fellows:

Henry A. Kohman, Ph.D. (University of Kansas), senior fellow.

Charles Hoffman, Ph.D. (Yale University).

Trueman M. Godfrey, B.S. (University of Kansas).

(May 12, 1913.)

19. ALUMINUM:

\$5,000 a year for 2 years, including apparatus fund.

Bonus: \$10,000.

Fellows:

Hugh Clark, Ph.D. (University of Pittsburgh).

Lester A. Pratt, Ph.D. (University of Pittsburgh).

(May 12, 1913.)

20. GLUE:

\$1,500 a year for 2 years + \$300 apparatus fund.

Fellow:

Ralph C. Shuey, B.S. (University of Kansas).

(May 12, 1913.)

21. SOAP:

\$1,500 a year for 2 years + \$300 apparatus fund.

Fellow:

Ben H. Nicolet, Ph.D. (Yale University).

(May 12, 1913.)

22. GLASS:

\$1,500 a year for 2 years + \$300 apparatus fund.

Bonus: \$3,500.

Fellow:

R. R. Shively, Ph.D. (University of Pittsburgh).

(July 14, 1913.)

23. RELATION OF ELECTRICAL POTENTIAL TO CATALYTIC ACTION:

\$1,500 a year for 2 years + \$300 apparatus fund.

Bonus: 5 per cent. industrial results.

Fellow:

Frank F. Rupert, Ph.D. (Massachusetts Institute of Technology).

(July 14, 1913.)

24. EXTRACTION OF COPPER FROM ITS ORES AND FROM COPPER "TAILINGS":

\$1,500 a year for 1 year + \$300 apparatus fund.

Fellow:

Charles O. Brown, M.A. (Cornell University).

(July 14, 1913.)

25. YEAST:

\$5,200 a year for 2 years, including apparatus fund.

Bonus: \$10,000.

Fellows:

F. Alex. McDermott, B.S. (University of Pittsburgh), senior fellow.

William Smith, Scholar (University of Pittsburgh).

Ruth Glasgow, M.S. (University of Illinois), bacteriologist.

James C. Cuthbert, Scholar (University of Pittsburgh).

(July 14, 1913.)

26. HARDENING OF FATS:

\$1,000 a year for 1 year + \$300 apparatus fund.

Bonus: 49 per cent. interest.

Fellow:

E. O. Rhodes, B.S. (University of Kansas).

(September 19, 1913.)

27. LEATHER SCRAP:

\$1,000 a year for 1 year + \$200 apparatus fund.

Bonus: 10 per cent. interest.

Fellow:

R. Phillips Rose, M.S. (University of Ohio).

(October 22, 1913.)

28. FERTILIZER:

\$2,500 a year for 2 years, including apparatus fund.

Bonus: \$5,000.

Fellow:

Earl S. Bishop, D.Sc. (Queen's University, Ontario, Canada).

(November 1, 1913.)

29. COPPER:

\$6,000 a year for 1 year, including apparatus fund.

Fellows:

F. R. Weidlein, A.M. (University of Kansas), senior.

H. D. Clayton, B.S. (Ohio State University).

G. A. Bragg, B.S. (University of Kansas).

(November 6, 1913.)

30. RADIATORS:

\$2,000 a year for 2 years, including apparatus fund.

Bonus: \$5,000.

Fellow:

J. C. Ballantyne, B.Sc. (University College, London).

(November 18, 1913.)

31. TURBINE ENGINES:

\$1,800 a year for 1 year, including apparatus fund.

Bonus: \$3,000.

Fellow: (not yet appointed).

(January 5, 1914.)

32. GLASS:

\$1,800 a year for 1 year, including apparatus fund.

Bonus: 25 per cent. interest.

Fellow: (not yet appointed).

(January 5, 1914.)

The total amount of money so far handed in by industrialists for expenditure in the little building mentioned above is \$183,800. The total fellowship list now runs at the rate of \$97,400 per year.

About the results of these fellowships, this much at this time may be stated:

1. Received a bonus of \$1,000.

2. On the basis of the experimental and investigative work accomplished has been extended through a third year.

3. On the termination of this fellowship the holder went over to the company at a salary of \$2,500 per year.

4. The bonus of \$10,000 has been acknowledged by the company and the first installment paid. The company then asked for a second fellowship at an increased rate and with a second bonus of \$10,000, which appears in this list as No. 18.

5. In recognition of the work of this fellowship the company on its expiration established a second fellowship at an increased rate, which appears in this list as No. 20.

6. On the termination of this fellowship, the fellow went over personally into his company with his process and in recognition of its success the company then established a second fellowship on the same subject at an increased rate, which appears in this list as No. 21.

7. On the conclusion of this fellowship, in lieu of the bonus, under certain conditions the proprietary rights in his process were conferred upon the fellow.

8. While this fellowship was successful, from the standpoint of the results of the investigation, it was a failure owing to changing circumstances in the specific example of the industry concerned.

9. This large and important fellowship, which had a tenure of two years, has been extended through a third year on the basis of the results accomplished. These results are of prime importance to the petroleum industry.

10. This fellowship, established for two years at \$4,000 a year, has been extended through a third year for the sum of \$6,000, the salary stipend of the senior fellow being raised from \$2,500 a year to \$4,000 a year.

11. This fellowship was a failure, owing in large measure to a lack of willingness on the part of the company concerned to cooperate with the administration and the fellow.

12. This fellowship is now in operation and it is believed that it will have a successful termination.

13. There is no question about the very success-

ful operation of this fellowship and of its ultimate results.

14. This fellowship has already yielded the essentials of an important industrial process. It has a very large importance to the institute, owing to the fact that the donor has made over all results to the institute to be used for the establishment of further researches by the institute.

15. The laboratory investigation of this subject has been completed and its large-scale working is now being arranged for. Pending the completion of the large-scale operation, the fellowship has been extended.

16. This investigation has proved so important that it has been extended through the addition of another fellowship, No. 24, at \$1,500 a year, and, subsequently, of still another, No. 29, at \$6,000 a year.

17. The original object of this fellowship proved impossible of an industrial solution, owing to the fact that investigation of the plant concerned showed that it contained nothing of potential industrial value. The object of the investigation was thereupon changed and the ultimate results are not yet determinable.

18. Was established by the same company on the basis of the success of No. 4. While it has been in operation only since September, it already unquestionably deserves its bonus.

19. A fellowship yielding results of prime importance.

20. Was established on the basis of the success of No. 5.

21. Was established on the basis of the success of No. 6.

22. Is already unquestionably successful.

23. A most interesting fellowship on a most interesting subject. This research is remarkable in that the donor desires that the institute should receive for its own purposes 70 per cent. of the results.

24. Established in correlation with No. 16. It is already yielding promising results.

25. A strong fellowship in operation only since September.

26. This fellowship was transferred from the University of Kansas. It has already yielded an important industrial process.

27. It is impossible to forecast the end of this fellowship.

28. Begins operation on January 5, 1914.

29. Was established in cooperation with fellowships No. 24 and No. 16. The results of this fel-

lowship would probably justify the total expenses of the whole fellowship system.

30. Went into operation a month ago.

31. Has been accepted but is not yet signed.

32. Has been accepted but is not yet signed.

In the spring of 1912 owing to ill health, the result of too much responsibility, arrangements were made to give me an associate director, Dr. Raymond F. Bacon, who came to me from the Bureau of Chemistry at Washington. Dr. Bacon's scientific prescience, his suggestive power in research, together with his sympathetic understanding of the traditions of the work and his personal loyalty have made him an ideal associate. Since the spring of 1913, he has been aided in his work of supervision through the appointment of Dr. E. Ward Tillotson as assistant director. Dr. Tillotson has already established the success of several fellowships through his personal supervision.

The administration of the institute consists at present of the director, with the associate director and assistant director. Their work of direction and supervision is greatly lightened by the senior fellows. It should be pointed out that the fellowships of the institute consist of two kinds, individual and multiple fellowships. An individual fellowship utilizes the services of one man, directly responsible to the administration; a multiple fellowship, the intensive services of several men under the direction of a senior fellow who in turn is directly responsible and under the administration. There are seven senior fellows in the institute. The adequate supervision of the thirty-nine fellows at present in the institute is in this way entirely practicable and explains the results obtained.

The \$97,400 per year at present being expended by this institute in the various researches in operation have been handed in to the institute by various companies in accordance with a definite agreement between each company concerned and the institute.

As this whole system of research is locked up in or depends upon these agreements, their importance warrants my insertion at this point of an agreement which is deemed by us at this time as representative of a reasonable arrangement. The one I submit is that of a multiple fellowship in blank.

COMPANY'S MULTIPLE FELLOWSHIP AGREEMENT

(Fellowship No. XXIX.)

THIS AGREEMENT made and entered into this _____ day of _____ 1913, between the

Mellon Institute of the University of Pittsburgh, of the City of Pittsburgh, Pennsylvania, hereinafter called the "Institute," and the _____, of _____, hereinafter called the "Company,"

WITNESSETH: that for the purpose of promoting the increase of useful knowledge, the parties hereto agree as follows:

1. The Company shall pay to the Institute annually in advance for a period of _____ years, beginning _____, 1913, the sum of _____ dollars (_____) for the foundation of a Multiple Industrial Fellowship to be known as _____, the exclusive purpose of which is _____

2. The Institute shall accept the sums so to be furnished by the Company and shall devote them to the furtherance of the problems of this Fellowship; and to this end all money received from the Company under this Agreement shall be paid over by the Institute in monthly installments to the holders of this Fellowship in such amounts as may be agreed upon by the Institute and the Fellows concerned, or expended for such apparatus and supplies related to this research as the Director of the Institute may deem it advisable to purchase and for traveling expenses related to the elucidation of the problems concerned. The Fellows shall be provided, at the expense of the Institute, with a separate laboratory and with such apparatus, supplies and reagents as in the opinion of the Director constitute a reasonable provision. The Company, on its part, shall cooperate with the Institute in this research by providing the Director thereof and the Fellows of this Fellowship with its sympathy and with whatever knowledge of the subjects of research it may possess, and, on approval of the Company, with its factory facilities for large-scale experimentation.

3. The holders of the Fellowships provided hereunder shall be appointed by the Committee of Management of the Institute upon the nomination of the Director in accordance with the terms of their formal letters of application to and as approved by the Director, and they shall give their whole time and attention to the object of the Fellowship, with the exception, if the Director so elect, of three hours a week which each shall give to instructional work in the University of Pittsburgh. The Fellows shall work under the advice and direction of the Director and shall from time to time through the Director for-

ward to the Company reports of the progress of their work. During the existence of the Fellowships provided hereunder the Company shall have the right, through and with the acquiescence of the Director, to employ and take into its regular service any or all of the Fellows of this Fellowship, upon terms to be agreed upon between the Fellow or Fellows and the Company, and the Institute shall appoint a successor to the Fellowship vacated by reason of the regular employment of one or more of the Fellows by the Company, provided the condition of the research work shall in the opinion of the Director make necessary or advisable the appointment of such successor.

4. The Institute, at the expiration of the Fellowship, shall return to the Company any money paid to it by the Fellow, in case any thereof shall remain unexpended for the purpose of this Fellowship.

5. Any and all discoveries made by the Fellows, or any of them, during the term of this Fellowship as well as all information obtained by them germane to the subjects of their investigation shall become the property of the Company, subject to the terms and provisions of this Agreement, and any Fellow making such discovery or obtaining such information shall promptly and without demand make revelations of all such information and discoveries. Such revelations shall be made to the duly designated representatives of the Company directly, or through the Director, as the Director may determine.

6. Any Fellow or Fellows making a discovery or invention germane to the subject of their investigation shall, at any time, at the option and expense of the Company, apply for letters patent, and shall upon demand assign such letters patent and any and all right to such invention to the Company under the conditions of this Agreement. In case the Company desires to keep secret such discovery or invention, or for any reason desires that letters patent shall not be applied for, the Fellow or Fellows shall not at any time apply for patent or patents in their own name, and shall not disclose such discovery or invention to others except as herein provided.

7. The Company shall, in addition to the sums paid to the Institute as foundation for the Fellowships, pay to the Fellows collectively a maximum cash bonus of _____ dollars (_____) or any part thereof which in the opinion of the Board of Arbitration (hereinafter provided for) is deserved by the Fellows of this Fellowship, and the amount of this payment and the

time or times of payment shall be decided by the Board of Arbitration upon application of either of the parties hereto. The relative distribution of the bonus to the individual Fellows concerned shall be wholly within the power of the Director to decide and determine.

8. In the event of any difference of opinion between the parties hereto as to the interpretation of this Agreement, or the rights of the respective parties to this Agreement, the matters in issue shall be referred to a Board of Arbitration, which Board shall consist of a representative of the Institute and a representative of the Company, and a third person whom these two shall select. The decision of this Board shall be obtained without recourse to the courts and when rendered shall be binding upon the parties hereto.

9. During the term of this Fellowship, the holders thereof may publish such results of their investigations as do not, in the opinion of the Company, injure its interests. On or before _____, 19—, the holders thereof shall complete a comprehensive monograph on the subject of their researches. The subject matter of such monograph shall not contain specific information of the process or methods of the Company but it shall be confined to a statement of new discoveries of scientific fact obtained by this Fellowship and such statement shall not contain data or information in regard to the cost of manufacture by any process revealed in such statement. A copy of this monograph shall be forwarded to the Company and a copy shall be signed and placed in the archives of the Institute until the expiration of three years from the time hereinafter provided for the termination of this Fellowship, when the Institute shall be at liberty to publish it for the use and benefit of the public.

In the event that in the opinion of the Company such publication at such time will unduly injure its interests, it shall have the privilege of appealing at any time for an extension of time of such publication to the Board of Arbitration provided for herein, which, after considering the appeal, shall, if in its opinion such publication will unduly injure the Company's interests, extend the time of publication to a time when in the Board's opinion publication will not unduly injure the interests of the Company.

10. The Fellowships provided under this Agreement shall terminate the _____ day of _____, 191—.

IN WITNESS WHEREOF, the parties hereto have

caused their names to be subscribed the day and year first above mentioned by their duly authorized officers.

Witness: MELLON INSTITUTE OF UNIVERSITY
OF PITTSBURGH

By _____

By _____

The permanent building which will be in occupation by the institute by next September is splendidly fitted to correspond with its needs. In order that the institute may not grow too large for maximum efficiency in its different researches and for the maintenance of its fraternal spirit it has been determined to limit its members to seventy fellows. As the present number of fellows is thirty-seven, this will necessitate a considerable increase in the directional and supervisory permanent staff. Perhaps I may be permitted to say here that I am eagerly on the watch tower for men possessed of the rare qualities requisite for such positions.

The Graduate School of Specific Industries which will be connected with the Institute on the completion of its building, I shall make the subject of a future statement.

Finally it may be said, on the basis of the two years intervening since my last statement to this journal, that this system of cooperation between industry and learning, between the factory and the university, has positively passed the tentative and experimental stage and that it now stands as a valuable and permanent relation to both. Any anxieties I may have are not now connected with this example of the system, but with my desire that it should be extended into other educational institutions. We believe that this can be accomplished by handing over to the universities for this service some of our own men inducted into a full knowledge of the working of this system through years of connection with it.

ROBERT KENNEDY DUNCAN

*THE NEW PERUVIAN EXPEDITION UNDER
THE AUSPICES OF YALE UNIVERSITY
AND THE NATIONAL GEO-
GRAPHIC SOCIETY*

LAST Saturday there sailed for Peru the topographical division of a new expedition. The chief engineer, E. C. Erdis, of the 1912 expedition, had sailed the week before. In a short time two more members of the expedition will sail, and as soon as the maps have been completed and are ready for use, the scientific members of the party will leave for the field. This will probably not be until early in 1915.

As in 1912 the expedition is under the joint auspices of Yale University and the National Geographic Society. Unlike former expeditions, it will cover a period of two years, instead of being confined to one field season. Three members of the expedition, the chief engineer, the chief assistant, and the assistant topographer, will be in the field for a year and a half, or more.

It is our plan to make a geographical reconnaissance of a portion of southern Peru, including the Cordillera Vilcabamba and portion of the Apurimac and Urubamba watersheds.

This region is a part of the eastern edge of the great Andean plateau. The Cordillera Vilcabamba is a chain of dissected mountains rising 16,000 to 20,000 feet above sea-level, situated between south latitudes 12 and 14. Their bases are clothed with tropical jungles, while their summits are mantled with snow and glaciers. In the main they are unexplored. As one of the most inaccessible parts of the Andes, they have been occupied from time to time by the ancient peoples of Peru. In this region are the ruins of Machu Picchu, Palcay and Choquequirau.

The reported presence of other ruins and the actual existence of some that have been seen, but not studied or mapped, make the region a particularly attractive area in which to study the problem of man's origin and distribution in South America.

The character of the land formations in the neighborhood of the ruins should enable some-

thing to be said in regard to the number of people formerly occupying the region, the causes of the location of the cities, buildings and forts, and the reasons for their final abandonment.

An examination of the ruins, studies of the styles of architecture, and of the artifacts and other remains that may be found fairly near the surface of the ground, should eventually enable a classification to be made, which, in connection with biological, physiographic, linguistic and historical studies, ought to result finally in unravelling the puzzle of the ancient civilization of South America. From the standpoint of biology, this area is believed to contain a large number of species new to science. From the standpoint of anthropology it is one of the least known and most fruitful areas in the Andes.

The plan of work will include the making of a topographical map of the region northwest of Cuzco between the Apurimac and Urubamba Rivers; a detailed geographical reconnaissance of the more lofty portions of the mountains, including a study of the large undescribed glaciated region; the establishment of two meteorological stations at different elevations for the taking of systematic records for two years; a study of the distribution and history of food plants of this region; the collection of data respecting the forms and distribution of vertebrates, particularly mammals and reptiles; a survey of the present Indians inhabiting this region, including a study of their dialects, the collection of anthropometric data, and the collection and study of the skeletal remains; an archeological reconnaissance of the entire area, and a continuation of the studies begun by the first expedition, looking toward a geographical interpretation of the Spanish chronicles of the era of discovery and exploration, with particular reference to the identification of ancient place names, the story of Machu Picchu and its connection with the history of the Incas.

The staff of the expedition consists of: Ellwood C. Erdis, chief engineer; Herbert E. Gregory, geologist (Silliman professor of geology in Yale University); George F. Eaton,

osteologist (curator of osteology in the Peabody Museum of Yale University); Albert H. Hardy, chief assistant; C. F. Westerberg, assistant topographer; H. S. Arnold, M.D., medical adviser; Philip A. Means, assistant in archeology; L. M. Kirkpatrick, secretary. The surgeon has not yet been named.

HIRAM BINGHAM,
Director

THE COMMITTEE OF ONE HUNDRED ON
SCIENTIFIC RESEARCH OF THE AMERICAN
ASSOCIATION FOR THE
ADVANCEMENT OF
SCIENCE

THIS committee, authorized by the council of the association and appointed at and after the Atlanta meeting by President Wilson and President Eliot with the advice of the committee of policy, met at the Cosmos Club, Washington, on the afternoon of April 20, 1914. Mr. Pickering was in the chair, and the following members were present:

Messrs. C. L. Alsberg, E. W. Brown, J. McK. Cattell, C. B. Davenport, K. E. Guthe, George E. Hale, Ross G. Harrison, L. O. Howard, C. S. Howe, William H. Howell, W. J. Humphreys, William W. Keen, C. Kenneth Mees, George A. Miller, E. L. Nichols, Arthur A. Noyes, Henry F. Osborn, E. C. Pickering, Ira Remsen, Frank Schlesinger, Elihu Thomson, O. H. Tittmann, Thomas L. Watson, Arthur G. Webster, William M. Wheeler and R. S. Woodward.

The membership of the committee was completed by election, and there was a long and important discussion on scientific research in America and the means by which it can be advanced by the committee. Among the questions fully discussed were (1) the use of research funds and the establishment of a central bureau under the auspices of the association, the National Academy or the Smithsonian Institution; (2) research work in educational institutions, the extent to which it is supported and should be regarded as the function of the institution and its professors and instructors; (3) the research work of industrial laboratories and its relation to the universities; (4) the selection of men in univer-

sities competent to undertake research work and the preparation that should be given to them, and (5) the fuller recognition and better opportunities that should be given to those who have unusual qualifications for scientific research. It was agreed that the principal work of the committee should be entrusted to sub-committees. The whole committee will meet at Philadelphia on the afternoon of Monday, December 28, 1914, at the hotel headquarters of the American Association.

Sub-committees were authorized in each of the five directions above noted. The three last-mentioned topics were emphasized, respectively, by Mr. C. Kenneth Mees, Mr. Ernest W. Brown and Mr. Theodore W. Richards, and a sub-committee on each of the subjects will be formed with their advice. The committees named are:

Executive Committee: E. C. Pickering, *Chairman*, Charles D. Walcott, William H. Welch, Edmund B. Wilson, J. McKen Cattell, *Secretary*.

Sub-committee on Research Funds: Charles S. Minot, *Chairman*, Simon Flexner, E. C. Pickering, R. S. Woodward, Charles R. Cross, *Secretary*.

Sub-committee on Research in Educational Institutions: Edward L. Nichols, *Chairman*, Edwin G. Conklin, Arthur A. Noyes, John M. Coulter, J. McKen Cattell, *Secretary*.

The full membership of the Committee of One Hundred is as follows:

Eliot, Charles W., president of the association, president emeritus of Harvard University, *Chairman*.

Pickering, E. C., director of the Harvard College Observatory, *Chairman of the Executive Committee*.

Adams, Frank D., professor of geology, McGill University.

Alsberg, C. L., chief of the Bureau of Chemistry, U. S. Department of Agriculture.

Ames, J. S., professor of physics, Johns Hopkins University.

Angell, J. R., professor of psychology, University of Chicago.

Baldwin, S. E., professor of law in Yale University and governor of Connecticut.

Baneroft, W. D., professor of physical chemistry, Cornell University.

Bessey, Charles E., professor of botany, University of Nebraska.

- Boas, Franz, professor of anthropology, Columbia University.
- Britton, N. L., director of the New York Botanical Garden.
- Brown, Ernest W., professor of mathematics, Yale University.
- Campbell, Douglas H., professor of botany, Stanford University.
- Campbell, W. W., director of Lick Observatory.
- Chamberlin, T. C., professor of geology, University of Chicago.
- Chittenden, R. H., professor of physiological chemistry, Yale University.
- Cole, Alfred D., professor of physics, Ohio State University.
- Conklin, Edwin G., professor of zoology, Princeton University.
- Cottrell, F. G., professor of physical chemistry, University of California.
- Coulter, John M., professor of botany, University of Chicago.
- Councilman, W. T., professor of pathology, Harvard University.
- Cross, Charles R., professor of physics, Massachusetts Institute of Technology.
- Davenport, C. B., director of the Station for Experimental Evolution, Carnegie Institution.
- Davis, William M., emeritus professor of geology, Harvard University.
- Day, Arthur L., director of the Geophysical Laboratory, Carnegie Institution.
- Dewey, John, professor of philosophy, Columbia University.
- Donaldson, H. H., professor of neurology, Wistar Institute of Anatomy.
- Fairchild, H. L., professor of geology, Rochester University.
- Farlow, W. G., professor of cryptogamic botany, Harvard University.
- Fisher, Irving, professor of economics, Yale University.
- Flexner, Simon, director of the laboratories, Rockefeller Institute for Medical Research.
- Franklin, Edward C., professor of organic chemistry, Stanford University.
- Gill, Theodore, professor of zoology, George Washington University.
- Goodale, George L., emeritus professor of botany, Harvard University.
- Guthe, Karl E., professor of physics, University of Michigan.
- Hale, George E., director of Mount Wilson Solar Observatory, Carnegie Institution.
- Harrison, Ross G., professor of comparative anatomy, Yale University.
- Hayford, John F., director of the College of Engineering, Northwestern University.
- Holmes, Joseph A., chief of the Bureau of Mines.
- Howard, L. O., chief of the Bureau of Entomology.
- Howe, Charles S., president of the Case School of Applied Science.
- Howell, William H., professor of physiology, The Johns Hopkins University.
- Humphreys, W. J., professor of meteorology, U. S. Weather Bureau.
- Hunt, Reid, professor of pharmacology, Harvard University.
- Jordan, David Starr, president of Stanford University.
- Keen, William W., emeritus professor of surgery, Jefferson Medical College, president of the American Philosophical Society.
- Kemp, James F., professor of geology, Columbia University.
- Leuschner, Armin O., professor of astronomy, University of California.
- Lillie, Frank R., professor of embryology, University of Chicago.
- Loeb, Jacques, head of department of experimental biology, Rockefeller Institute for Medical Research.
- MacDougal, D. T., director of the department of botanical research, Carnegie Institution.
- Maclaurin, R. C., president of the Massachusetts Institute of Technology.
- McMurrich, J. Playfair, professor of anatomy, University of Toronto.
- Mall, Franklin P., professor of anatomy, Johns Hopkins University.
- Marvin, C. F., chief of the U. S. Weather Bureau.
- Mees, C., Kenneth, Eastman Kodak Company, Rochester, N. Y.
- Mendenhall, T. C., president emeritus, Worcester Polytechnic Institute.
- Michelson, A. A., professor of physics, University of Chicago.
- Miller, G. A., professor of mathematics, University of Illinois.
- Millikan, R. A., professor of physics, University of Chicago.
- Minot, Charles S., professor of comparative anatomy, Harvard Medical School.
- Moore, E. H., professor of mathematics, University of Chicago.
- Moore, George T., director of the Missouri Botanical Garden.

- Morgan, T. H., professor of experimental zoology, Columbia University.
- Morley, Edward W., emeritus professor of chemistry, Western Reserve University.
- Morse, Edward S., director, Peabody Academy of Science.
- Moulton, Forest R., professor of astronomy, University of Chicago.
- Neal, Herbert V., professor of biology, Tufts College.
- Nichols, Edward L., professor of physics, Cornell University.
- Noyes, Arthur A., director of the research laboratory of physical chemistry, Massachusetts Institute of Technology.
- Noyes, W. A., professor of chemistry, University of Illinois.
- Osborn, Henry F., president of the American Museum of Natural History, research professor of zoology, Columbia University.
- Pearce, R. M., professor of research medicine, University of Pennsylvania.
- Putnam, E. W., professor emeritus of anthropology, Harvard University.
- Remsen, Ira, professor of chemistry, Johns Hopkins University.
- Richards, Theodore W., professor of chemistry, Harvard University.
- Rosa, Edward B., chief physicist, Bureau of Standards.
- Schlesinger, Frank, director of the Allegheny Observatory.
- Sedgwick, William T., professor of biology, Massachusetts Institute of Technology.
- Smith, E. F., provost of the University of Pennsylvania.
- Smith, G. Otis, director of the U. S. Geological Survey.
- Smith, Hugh M., U. S. commissioner of fisheries.
- Smith, Theobald, professor of comparative pathology, Harvard University.
- Stieglitz, Julius, professor of analytical chemistry, University of Chicago.
- Stiles, Ch. Wardell, zoologist, U. S. Public Health Service.
- Stratton, Samuel W., director of the Bureau of Standards.
- Thomson, Elihu, Thomson-Houston and General Electric Companies.
- Titchener, Edward B., professor of psychology, Cornell University.
- Tittmann, Otto H., chief of the U. S. Coast and Geodetic Survey.
- Van Hise, Charles R., president of the University of Wisconsin.
- Walcott, Charles D., secretary of the Smithsonian Institution.
- Ward, Henry B., professor of zoology, University of Illinois.
- Watson, Thomas L., professor of economic geology, University of Virginia, and director of the Virginia Geological Survey.
- Webster, Arthur G., professor of physics, Clark University.
- Welch, William H., professor of pathology, Johns Hopkins University, president of the National Academy of Sciences.
- Wheeler, William M., professor of economic entomology, Harvard University.
- Whitney, Willis R., director of the research laboratory, General Electric Company.
- Wilson, Edmund B., professor of zoology, Columbia University.
- Woodward, Robert S., president of the Carnegie Institution of Washington.
- Cattell, J. McKeen, professor of psychology, Columbia University, *Secretary*.

SCIENTIFIC NOTES AND NEWS

DR. WOLDEMAR VOIGT, professor of theoretical physics at Göttingen, will next year be the visiting professor from Germany to Harvard University.

On the recommendation of the council and of the special committee on the Hayden Award the Academy of Natural Sciences of Philadelphia has this year conferred the memorial gold medal on Henry Fairfield Osborn in recognition of his distinguished work in vertebrate paleontology.

DR. SIMON FLEXNER, director of the laboratories of the Rockefeller Institute for Medical Research, has received notice through the French ambassador in Washington that the cross of chevalier of the legion of honor has been conferred upon him by the president of the French Republic. This honor has been bestowed in recognition of the services which Dr. Flexner has rendered to medical science through his own discoveries and through his administration of the Rockefeller Institute. Special mention is made in the award of the assistance given to France at the time of the epidemic of cerebro-spinal meningitis, which prevailed in 1909, by sending to the Pasteur

Institute in Paris a supply of anti-meningitis serum which was successfully used in combating that epidemic.

SURGEON-GENERAL WILLIAM C. GORGAS, U. S. Army, has been awarded the Dr. Louis Livingston Seaman medal by the American Museum of Safety as a recognition of his work in making the Panama Canal Zone habitable and sanitary.

DR. JOSIAH ROYCE, since 1885 professor of the history of philosophy at Harvard University, has been transferred to the Alford professorship of natural religion, moral philosophy and civil polity, vacant by the retirement of Professor Palmer.

DR. JULIUS VON HANN, professor of cosmical physics at Vienna, has celebrated his seventy-fifth birthday.

PROFESSOR C. S. SHERRINGTON, Waynflete professor of physiology in the University of Oxford, has been elected a member of the Royal Danish Academy of Sciences.

ZÜRICH UNIVERSITY has conferred the honorary degree of doctor of natural sciences upon Professor Alfred Werner, of Zürich, winner of the last Nobel Prize for chemistry.

DR. LAWRENCE MARTIN, associate professor of physiography and geography at the University of Wisconsin, has been elected a corresponding member of the Kaiserlich-königliche Geographische Gesellschaft in Vienna.

SECRETARY LANE, of the Department of the Interior, has appointed Professor R. H. Fernald, of the University of Pennsylvania, as consulting engineer to the Bureau of Mines. He will be sent to England, France, Belgium, Germany and Austria to investigate improvements with gas producers in the development of metallurgical and power operations.

DR. HANS MURSCHHAUSER, of the Akademische Kinder-Klinik in Düsseldorf, has been appointed research associate of the Carnegie Institution of Washington, attached to the nutrition laboratory at Boston.

DR. FREDERICK M. MEADER has resigned as city bacteriologist of Syracuse, and has been succeeded by Dr. Oliver W. H. Mitchell, assist-

ant professor of bacteriology and preventive medicine in the University of Missouri. Dr. Mitchell also succeeds Dr. Leverett D. Bristol as assistant professor of bacteriology in Syracuse University.

MR. ALFRED E. CAMERON, board of agriculture scholar in entomology, Manchester, England, is spending the summer at the entomological department of the Agricultural Experiment Station, New Brunswick, N. J. He has recently arrived from England.

PROFESSOR FRANCIS E. LLOYD, of McGill University, will spend the period from May 1 to September 15, at the coastal laboratory of the Carnegie Institution of Washington, Carmel-by-the-Sea, Calif.

MR. STEWART CULIN, curator of the department of ethnology of the Brooklyn Museum, is at present in the far east in order to collect ethnological material. His itinerary has taken him to Japan, China, Korea, India and Ceylon.

THE Congo expedition of the American Museum of Natural History under Messrs. Herbert Lang and James Chapin, which in cooperation with the Belgian government has been carrying on active field work in central Africa for the past four years, will return to New York early in the summer.

DR. HERMANN VON SCHRENK, pathologist to the Missouri Botanical Garden, delivered a series of five lectures before the members of the department of forestry of the University of Toronto, in March, on "Diseases of Trees and Structural Timbers."

MRS. CHRISTINE LADD-FRANKLIN gave, on April 20, 21 and 22, three lectures at the University of Chicago as follows: "The Bridge between the New Logic and the Old," "The Indispensable Requirements of a Color Hypothesis," "Graphic Representation of Color Relations and Recent Views on Color."

THE second open meeting of the Society for Biological Research of the University of Pittsburgh for the year 1913-14 was held on April 16, at which time Dr. John F. Anderson, director of the hygienic laboratory of the U. S. Marine Hospital and Public Health Service, gave an

address on the "Etiology and Distribution of Typhus Fever."

DR. BARTON WARREN EVERMANN, director of the Museum of the California Academy of Sciences, delivered the address at the annual meeting of the Beta Kappa Alpha Society of the University of California, at Berkeley, on the evening of April 16. His subject was "The Alaska Fur-seal Herd and its Proper Management."

THE building of the College of the City of New York, hitherto known as the Mechanic Arts Building, will, by vote of the trustees, hereafter be called "Compton Hall," after Professor Alfred G. Compton, late head of the department, who died in the autumn of 1913.

THE municipality of Saint-Georges-sur-Cher has decided to erect a monument to Bretonneau, of Tours, one of the distinguished names in the history of French medicine, who was born there in 1774.

PHILIPPE EDOUARD LEON VAN TIEGHEM, eminent French botanist, died in Paris on April 28 at the age of seventy-five years.

DR. KARL CHUN, professor of zoology at Leipzig, distinguished for his oceanographic studies, has died at the age of sixty-two years.

DR. PAUL EHRENREICH, the distinguished ethnologist, docent in the University of Berlin, has died at the age of fifty-eight years.

PROFESSOR ADOLF FISCHER, director of the Museum for Asiatic art, founded last October at Cologne, has died at the age of fifty-eight years.

THE medical college of Cornell University and the General Memorial Hospital will establish a cancer hospital, towards which it is said \$1,000,000 have been subscribed, including \$500,000 from Dr. James Douglas.

THE cornerstone has been laid for a building for a Servian Academy of Science in Belgrade, the cost of which is to be about a million dollars.

THE Memorial Institute for Infectious Diseases, of Chicago, has moved into its new building at 629 South Wood St., to which address all communications should be sent. This is

also the new address of *The Journal of Infectious Diseases*.

THE late Mr. Henry Bloom Noble, of Douglas, Isle of Man, left practically all his estate for educational and charitable purposes in the island. The trustees of his will have decided to devote £20,000 for the fostering of agriculture.

THROUGH the generosity of Mr. George Manierre, of Chicago, the mounted skeleton of the American mammoth which has for many years been exhibited in the museum of the Chicago Academy of Sciences, has been transferred to the Field Museum of Natural History. This skeleton long remained the only mounted skeleton of the mammoth in America and it still forms one of the best representatives of this animal known.

THE American Museum of Natural History has acquired from the estate of the late Edwin E. Howell, of Washington, a well-known collector and dealer, the entire collection of meteorites which belonged to his establishment at the time of his death. The collection consists of representatives of fifty-four falls and finds, aggregating about one hundred kilometers in weight. It includes two which have not been heretofore represented in the museum, namely, the Ainsworth and Williamstown irons. This acquisition was made possible through the generosity of Mr. J. P. Morgan.

AFTER a conference with the trustees of the University of Pennsylvania following the close of the trial of Professor J. E. Sweet for cruelty to animals and the disagreement of the jury, Dean William Pepper, of the department of medicine, announced that the continuation of the experimental work in the medical school was authorized. It was agreed by all that the university owes it to humanity to continue the work without interruption.

LAST spring the attention of the Maine Agricultural Experiment Station was called to maggots infesting blueberries towards the end of the season. Accordingly larvæ were reared and the insect ascertained to be the same species which infests the apple, *Rhagoletis pomonella*.

APART from the governments and government departments which will be represented at the International Congress of Tropical Agriculture to be held at the Imperial Institute, London, from June 23 to 30, a number of societies, chambers of commerce and associations, foreign as well as British, have indicated their intention to support the congress, and most will send delegates. It is already known that the congress will be attended by members from the following countries: Austria, Egypt, France, Germany, Holland, Italy, Japan, Portugal, Russia, the United Kingdom, the United States, Ceylon, East Africa, Gold Coast, Honolulu, India, Jamaica, Java, Leeward Islands, Nigeria, Sierra Leone, Straits Settlements and Federated Malay States, Trinidad and Uganda.

It is announced that arrangements are being made for the holding in Edinburgh, in September next, of a conference on the various aspects of the physical sciences in their application to the study of the phenomena of weather. Sir John Murray had consented to act as president, but now new arrangements must be made. It is planned to open the conference on September 8, and to continue its work during the four following days. Those interested should send their names to the secretary of the organizing committee at the Meteorological Office, South Kensington, London, S. W.

THE thirteenth general meeting of the Association of Economic Biologists was held at the Imperial College of Science and Technology, London, on April 10 and 11. Professor Robert Newstead presided. According to the report of the London *Times* Mr. A. G. L. Rogers, of the Board of Agriculture, communicated the results of the International Phytopathological Conference lately held in Rome with the object of considering how united action may be taken for checking the importation of plant diseases. There are two ways of dealing with a center of plant infection. The first is to forbid the entry of plants from the infected district or country. The alternative is for the adminis-

trative authorities in the infested country to take the necessary steps for extirpating the pest within their borders; and to issue a guarantee of freedom from infection with all lots of the suspected produce. This procedure is an impossibility in the case of the bulky crops of what in France is called "La Grande Culture," as no staff of specialists could deal with the amounts grown. The international delegates therefore unanimously agreed to exclude these (including all grains) and the grape vine from their provisions, the various nations being left to protect themselves from diseases of staple crops by individual action as at present. The recommendations, however, provide for including such produce as fruit, flowers and bulbs in the proposed convention, which at present awaits ratification, all the powers except the United States having provisionally agreed to the principle of united action. Certain powers, while not prepared to relinquish the right of inspecting imported produce included in the provisions of the convention, intimated their willingness to let these rights be in abeyance so long as exporting countries fulfilled their obligations.

It is planned to take the biological work of the University of Utah Summer School to a mountain laboratory during the last three weeks of the course. Animal ecology and some systematic study of flowering plants will be the parts of the work best adapted to this plan. The regular session will begin on June 8 and close on July 17, the change of base for biology to be made on June 26. Silver Lake, at the head of Big Cottonwood Canyon, thirty miles from Salt Lake City, altitude 8,728 feet, has been chosen as the spot for beginning mountain station work in Utah. Here in a setting of rugged peaks lie a half dozen small gems of mountain lakes, one at an altitude of 9,920 feet, and a beautiful little mountain valley in which rise from innumerable sources the headwaters of Big Cottonwood Creek, a typical mountain stream. From the tops of these peaks to the warm and hot springs, the sulphurous and salt waters, the desert and the Great Salt Lake itself in the valley near the university, stretches a wide va-

riety of conditions to receive attention in ecology. Persons desiring further information may communicate with Dr. Charles T. Vorhies, University of Utah, Salt Lake City.

MR. C. V. HODGSON, of the Coast and Geodetic Survey, Department of Commerce, has recently left Washington for the southwestern part of the United States, where he will have charge of a party for the determination of the astronomic latitude of triangulation stations established by the Coast and Geodetic Survey and the United States Geological Survey, between Barstow, Tex., and the Pacific Ocean. Many of these stations are on mountains as much as 10,000 feet in height. The results of this work will be used principally for geodetic purposes, that is, the determination of the figure of the earth and the distribution of material in the earth's crust. The means of transportation for this party will be a 1½-ton automobile truck which was used successfully on similar work between Denver, Col., and the Canadian border in the season of 1913. A similar truck had been employed also in 1912 on the 49th parallel boundary survey between the United States and Canada. The cost of the work during the season of 1913 is estimated as only one half what it would have been if horses and wagons had been used for transportation. The saving in the coming season is expected to be even greater, as the country to be traversed is arid or semiarid and the transportation of water and forage for stock would have been a difficult problem. It is expected that the work will continue until late in the autumn.

UNIVERSITY AND EDUCATIONAL NEWS

THE new buildings of Zürich University were formally opened on April 19. The buildings, which cost about \$1,700,000, stand on rising ground overlooking both lake and city.

DR. THEODORE C. JANEWAY, Bard professor of the practise of medicine in Columbia University, has accepted the professorship of medicine in Johns Hopkins University under the full time basis made possible by the gift of \$1,500,000 by the General Education Board.

DR. MAZYCK P. RAVENEL, professor of medical bacteriology in the University of Wisconsin, and director of the public health laboratory, has accepted the chair of preventive medicine in the University of Missouri.

THE board of regents of the State University of Washington has appointed a committee of three to consider the selection of a president and has requested the faculty to choose a like committee, which it has done by secret ballot. This joint committee will report to the faculty and to the regents.

DR. E. R. CLARK, associate in anatomy at Johns Hopkins University, has accepted an appointment to the chair of anatomy in the University of Missouri.

DR. LEVERETT D. BRISTOL has left Syracuse University to take charge of the North Dakota state laboratory.

At the College of the City of New York Professor William Fox has been made full professor of physics and head of the department and Professor Laurel has been promoted to be full professor of mathematics.

DR. WILLIAM HALLOCK PARK, professor of bacteriology and hygiene in the New York University and Bellevue Hospital Medical College, has been elected dean of the college by the council of New York University to succeed the late Dr. Egbert le Fevre.

DR. ALBRECHT BETHE, professor of physiology at Kiel, has accepted a call to Frankfurt.

PROFESSOR DR. H. MERKEL, professor of pathological anatomy at Erlangen, has been called to Munich.

DISCUSSION AND CORRESPONDENCE

MULTIPLE FACTORS IN HEREDITY

IN SCIENCE, April 10, 1914, Professor Ramaley refers appreciatingly to the work of Dr. MacDowell on size inheritance in rabbits, which was carried out in my laboratory, and concludes that this work essentially substantiates Davenport's conclusion that the apparent blend of human skin color in mulattos is due to two distinct Mendelizing factors possessed by the negro, but lacking in the white races.

.. Professor Ramaley's note might lead one to infer that since Dr. MacDowell's work was carried out under my supervision and since his paper has been published with my approval, therefore I (in common with Mendelians generally) share the views expressed concerning Mendelian factors in size inheritance, but this is not entirely true, and to avoid further possible misunderstanding I write this note. Dr. MacDowell's observations I believe to be accurate; they were made with great care and were checked in every possible way. I have kept in close touch with his work at every stage of its progress and have found it unimpeachable. Few investigators with whom I have been associated have shown such aptitude for exact and critical work as he displayed from the beginning. I endorse his observations fully.

But the facts observed are capable of different theoretical interpretations. In regard to these I have encouraged in Dr. MacDowell the fullest freedom of choice. He has adopted one for which much can be said, that of multiple Mendelian factors, which at times has appealed to me strongly, and the argument for which I have presented elsewhere ("Heredity," D. Appleton & Co., 1911) at some length. This theory has also been developed independently by Lang (1910), East (1910), Emerson (1910) and others. It accounts for the facts fully if certain basic assumptions are allowed, about which, however, I am growing more skeptical the more closely I examine them. Dr. MacDowell, in the passage quoted by Professor Ramaley, truthfully says of this theory, "It goes hand in hand with the mutation and pure-line doctrines of De Vries and Johannsen." But suppose one is not prepared to accept those doctrines, what then becomes of the multiple factor hypothesis? It is left without adequate basis. If the multiple factor hypothesis must stand or fall with the pure-line doctrine, I for one can not accept it, for the foundations of the pure-line doctrine appear to me very insecure.

What in brief are the facts regarding size inheritance which call for explanation?

Fortunately, observers are quite in agreement concerning them.

1. Occasionally an unmistakable Mendelizing factor is concerned in size inheritance. One was discovered by Mendel himself (1866) and its existence has been repeatedly verified, namely, the differential factor between tall and dwarf races of garden-peas. Tall and dwarf conditions in other plants behave in a similar way, that is as Mendelian alternative conditions showing both dominance and segregation in crosses. Brachydactyly in man is a variation like dwarfness in plants, in which the growth habit is altered, the skeleton being abnormally short and compact throughout. This character is a Mendelian dominant (Farabee, 1905, Drinkwater, 1908). The shorter, more compact form of Dexter cattle, in contrast with the Kerry breed, is a Mendelian character (Jas. Wilson, 1909) probably similar in nature. Doubtless the same was true of the short-legged Ancon sheep mentioned by Darwin (1878, "Animals and Plants").

From the mere fact that a Mendelian factor may be involved in a size difference, it by no means follows that *all* size differences are due to Mendelian factors. Such Mendelizing factors affecting size as have just been enumerated are distinctly rare. They are not discoverable at all in the cases studied by MacDowell, which involve neither dominance nor segregation in a 1:2:1 ratio. Even in cases involving an unmistakable Mendelian factor, as the tall-dwarf cross in peas, it is not to be supposed that no other factors affect size. For are all dwarf peas of the *same* height, or are all tall peas of the *same* height? No, there are differences among each sort, differences which are heritable also, since one dwarf variety differs from another in its mean height.

2. Ordinary differences in size (such as do not involve a change in the growth habit) among animals or plants do not Mendelize in the ordinary acceptation of the term. When races are crossed which differ widely in size, the first filial (F_1) generation is intermediate between the parents and often not more variable than one of the parent races. But the

second filial (F_2) generation, though still intermediate, commonly shows increased variability, the range of which may even extend into or include the size range of one or both parent races. This *increased variability* of the F_2 generation is the only evidence of Mendelism in size crosses. In 1911 I was inclined to regard it as *sufficient* evidence, but in this I was clearly mistaken, as a moment's consideration will show. It would be sufficient only (1) if the size differences were due *wholly* to Mendelian factors, and (2) further these factors were invariable, that is quantitatively always the same. But neither of these assumptions can be regarded as established. On any hypothesis size differences must depend on many mutually independent factors or causes. This is the prime significance of a frequency-of-error variation curve, however produced. It would be rash to assume that all the factors concerned are *Mendelizing* factors, in the total absence of the two usual accompaniments and criteria of Mendelism, dominance and segregation in recognizable Mendelian ratios.

The question whether Mendelian factors are constant or inconstant has been discussed from different points of view by my colleague Dr. East and myself in the *American Naturalist* (1912), he maintaining their constancy on the ground that they are subjective merely, while I have thought it necessary to assume for them an objective existence in the germ-cell, and am unable to discover any evidence of their constancy from the behavior of germ-cells. It is, of course, possible, as Dr. East maintained, to formulate a description of all heredity in terms of (purely subjective) Mendelian units, provided more and more units are from time to time created (by imagination) as the objective facts show the organism changed. But such an extension of Mendelism fails to interest me, as I think it does many of my readers. What we want to get at, if possible, is the objective difference between one germ-cell and another, as evidenced by its effect upon the zygote, and it is the constancy or inconstancy of these objective differences that I am discussing. If these are quantitatively changeable from generation to genera-

tion, then change in the variability of the zygotes composing a generation might arise without factorial recombination.

By way of illustration let us consider the simplest conceivable case. Suppose two organisms to differ by a single genetic factor for size. Suppose one organism to be of size 4, the other of size 8. On crossing, if each transmits its own condition and dominance is lacking, an intermediate is formed, size 6. On the theory of gametic purity, the gametes formed by this heterozygote of intermediate size (6) should be 4 and 8, respectively, and the next generation of zygotes (F_2) should be as follows:

Classes of zygotes	4,	6,	8,
Expected frequencies	1,	2,	1.

Here we note that a large part of the F_2 generation is intermediate in character, as was F_1 , but F_2 is more variable than F_1 , falling into three classes instead of one. This is the regular Mendelian way of viewing size inheritance, gametic purity being assumed. But is the assumption necessary or justifiable? Suppose the assumed size factor were *modifiable* or partially blending, so that 4 and 8, after association in the F_1 zygote, emerged as 5 and 7, respectively, in the gametes. Then F_2 would be:

Classes of zygotes	5,	6,	7,
Expected frequencies	1,	2,	1.

In this case, as well as in the supposed case of pure gametes, we should observe an F_2 more variable than F_1 , though the *extreme* conditions of the parent organisms crossed would not be attained in F_2 (as, in fact, they rarely are). But even the recurrence of such extreme conditions as those of the grandparents might be explained as due to occasional failure of the gametes associated together in F_1 to modify each other.

Now I do not advocate either of these explanations. I present the second merely to show that the first is not the only conceivable explanation, and that I was earlier wrong in supposing an *increase* of variability *prima facie* evidence of the occurrence of *more than* a single Mendelizing factor. It might equally

well be regarded as evidence of a *single* Mendelizing factor, quantitatively variable.

If we set out by assuming that a Mendelian factor is invariable, then we are forced to assume, whenever genetic variation is observed in an organism, that this is due to an *additional* Mendelian factor. This is the real basis of the multiple factor hypothesis as applied to size inheritance, though not, of course, the historical one. But to reason thus is merely to pile one assumption upon another, which is not to advance science, whatever it does for a system or a terminology; but with these we are less concerned than with knowing the exact truth and in stating it as clearly and concisely as possible.

What now of human skin color, is this or is it not Mendelian in inheritance? At present I consider this largely a question of terminology. The *facts* appear to be very similar to those observed for body-size in rabbits, and for other quantitative characters in animals and plants. F_1 is intermediate; F_2 is also intermediate, but more variable than F_1 . If we call this Mendelism, we shall need to explain that it is not the Mendelism of Mendel himself, but original Mendelism *plus* (1) the assumption of gametic purity, *plus* (2) the assumption of factorial constancy, *plus* (3) the assumption of factorial multiplicity.

JAVEL WATER—A SIMPLIFIED AND CORRECTED SPELLING

IN his "Grand dictionnaire universel du XIX^e Siècle" (Paris, 1873), Pierre Larousse tells us that there used to stand upon the banks of the Seine in the suburbs of Paris in what is now the "XVe arrondissement" a solitary mill, sheltered by trees, where bathers and fishermen used to rest and partake of refreshments. This mill was known as the "moulin de Javel" and the lexicographer elsewhere states that this word is a variant of *javeau*, which means an island of sand and mud, a sandbank, although in this instance

it is no doubt a proper name. The word *javelle* (cf. English, provincial, gavel), signifying an unbound sheaf or a bundle of grain smaller than a sheaf, is of different origin.

Upon the site of the old mill the village of Javel was founded in 1777 by the Count of Artois, who established a chemical works. The first directors of the works, Messrs. Alban and Vallet, were the originators of Javel water, which they prepared in 1792 by passing a current of chlorine through a solution of 2,440 kilos of "sub-carbonate" of potassium in 17 kilos of water. Larousse also refers explicitly to the erroneous spelling *eau de javelle*, employed by some authors. Littré in his "Dictionnaire de la langue française" (Paris, 1873) employs this erroneous spelling.

Unfortunately, the dictionary of the French Academy (7th edition, Paris, 1878) sanctioned the spelling "Javelle" for both the name of the mill and the derived name of the bleaching liquor, adding error to error in describing the liquid as a solution of potassium *chloride* in water ("L'eau de javelle est du chlorure de potassium en dissolution dans l'eau").

With such authority behind it, it is not surprising that the *-elle* ending has come into very general use. Yet a number of the more careful French and English writers employ the correct form of the word. Among such are Girard in "La grande encyclopédie" (article "Chlorures décolorants"); Emile Bouant in his "Dictionnaire de chimie" (Paris, 1888); Moissan in his "Chimie minérale" (1904-6); Edmund Knecht in the Encyclopedia Britannica, eleventh edition (article "Bleaching"); and Sir Edward Thorpe in his "Dictionary of Applied Chemistry" (1912). In Germany and America, as far as I have observed, the erroneous spelling is universally adopted. And our dictionaries of the English language appear likewise to be unanimously wrong. Not even the New Standard Dictionary (1913), which gives the simplified spellings of the Carnegie board, makes the least reference to the shorter form of this word.

A certain amount of confusion is prevalent also regarding the signification of the term

"Javel water." Originally it meant the liquor prepared by action of chlorine on dilute potash solution. In so far as its bleaching effect is concerned such a liquor is essentially a solution of potassium hypochlorite. It was inevitable, however, that when, through the cheapening of sodium compounds, potassium hypochlorite was superseded by the sodium salt, the name popularly applied to the bleaching liquor should undergo a change in signification. The fact that sodium hypochlorite solution was already employed in pharmacy under the name of *Labarraque's liquor* could not affect this change. Pharmaceutical language is too esoteric and popular habit too persistent to render it possible for the pharmaceutical term to supplant the established usage of the textile trade. I take it, then, that we must expect the sodium hypochlorite-chloride mixture to continue to be known as "Javel water." Such confused statements, however, as the following—let us hope a slip of the pen—are not to be excused even in a writer whose subject is one relating to textile chemistry. It occurs at p. 234 of Pellew's "Dyes and Dyeing," an excellent popularizing exposition of the triumphs of synthetic chemistry in this fascinating field:

The potash and soda compounds, known respectively as Labarraque's solution and Javelle water, are less active and powerful than bleaching powder, but have the same general properties.

It is to be hoped that Mr. Pellew's readers will not be misled by either his definitions or his spelling.

MACDONALD COLLEGE,
QUEBEC, CANADA,
February 27, 1914

SCIENTIFIC BOOKS

Manual of Petrographic Methods. By ALBERT JOHANNSEN, Ph.D., Assistant Professor of Petrology, the University of Chicago. New York, McGraw-Hill Book Co. 677 pages, 770 figures in text and as whole page plates. \$6.00 net.

The methods of microscopic petrography, like other laboratory methods, have advanced

steadily in number and in complication during the fifty years of their practise, keeping pace with the increasing number of workers, the aim at greater accuracy and the developments of the petrographic microscope and its accessories. The author states in the preface that "the desire of an increasing number of students for more complete information in regard to modern petrographic-microscopic methods than is to be found in any English work on the subject" has led to the preparation of this book, but the reviewer knows no more complete and up-to-date treatment of this special subject in any language, for in most cases such works combine the general and theoretical part with a description of the individual minerals, while in this work only the methods are dealt with, but with a thoroughness, especially regarding the applications of optical mineralogy, which is of great value to the advanced student and investigator. Beginning with a short introductory chapter on crystallography and a thorough treatment of stereographic projection (so necessary for some of the more recent microscopic methods), chapters follow on the transmission of light through crystals, with a very complete and practical treatment of such topics as lenses, the petrographic microscope and the innumerable accessories which are now available, while the following chapters, comprising 300 pages, or nearly half the book, give a very complete account of the practical methods of application of the principles and instruments previously described. A somewhat briefer but sufficient account of the determination of specific gravity, mechanical separation of rock minerals, microchemical reactions, preparation of thin sections, etc., fills the remaining pages. The book is clearly printed and compact, notwithstanding the extended text and many figures; it represents a vast amount of careful, discriminating and constructive work on the author's part, as, for instance, is shown by the bibliography at the end of each chapter, and should be invaluable in its special field.

JOHN E. WOLFF

HARVARD UNIVERSITY

Catalogue of the Lepidoptera Phalaenæ in the British Museum. Vol. XIII. Noctuidæ (part). By SIR G. F. HAMPSON, Bart. London, 1913. Pp. xiv + 609.

In this volume the consideration of the Noctuidæ is continued, the subfamily Catochalinae being concluded from Vol. XII., the Momiinae and Phytometrinæ (better known as Plusiinae), being given in full. There are 70 genera and 679 species included, besides some unrecognized ones. Colored plates CCXII. to CCXXXIX. accompany the volume.

Some of our most familiar names disappear, not by necessity, but by the author's non-recognition of the names in Hübner's "Tentamen" and "Zuträge." *Euclidia* Hübn. (Tent.) is replaced by the totally unfamiliar *Gonospileia* Hübn. (Verz.); *Agnomonina* Hübn. by *Argyrostromis* Hübn. (Verz.); *Plusia* Hübn. (Tent.) by *Phytometra* Haw., which changes the familiar sub-family Plusiinae to Phytometrinæ. However, this is in part set off by the retention of *Phurys* Guenée, which should have been replaced by *Crochiphora* Hübn. (Zutr.). According to the rules of nomenclature it appears to us that Hampson is clearly wrong in discarding these names.

On page 188, my species *distilla* is made a synonym of *Safia amella* Guen., but it is, in fact, abundantly distinct.

On page 207, *Zale* Hübn. is used instead of *Phæocyma* Hübn., by page priority, although the late J. B. Smith used *Phæocyma* in the monographic treatment of the American species. We are in favor of Hampson's action, and mention it only because it was held at the National Museum at the time that Smith could use either name he chose.

On page 331 some corrections of previous volumes appear. Our familiar genus *Erebis* replaces *Nyctipao* (Vol. XII., p. 273), a purely Asiatic genus and is lost to us. Likewise *Melipotis* Hübn. replaces *Ercheia* Walk., an old world genus, and disappears from our lists.

Under the Momiinae, my genus *Zazunga*¹ should have been included, with two species *zetacelis* and *opinor*. It would fall in the

table with *Elydnodes*, but the thorax is clothed with hair only.

HARRISON G. DYAR

Einführung in die Vererbungswissenschaft.

By RICHARD GOLDSCHMIDT. Second edition. Leipzig, Wilhelm Engelmann. 1913. Pp. 546. Price 14 marks.

The second edition of this work has been somewhat enlarged and in part rewritten. The first alteration to challenge attention is the thorough rearrangement of certain parts of the book. The chapters on Mutation and on the Inheritance of Acquired Characters are related to one another, and both are deferred to near the end of the book, after the sections on hybridization and sex determination. In the first edition those chapters are in the early part of the book, immediately after the discussion of variation. Graft hybrids and chimeras, instead of following hard upon Mendelian hybrids, are not discussed until after sex determination. Other chapters of the old edition are divided and the parts recombined. For example, the cellular basis of heredity is taken up in connection with sex determination, instead of independently; while minor sections are freely shifted under new captions. These changes appear to the reviewer to be in the interest of logical presentation.

The most extensive addition to the book is in the treatment of sex determination, sex inheritance, etc. These chapters are enlarged to the extent of about 35 pages. The striking feature of this enlargement is a proposed new formula for sex inheritance. Each sex is represented as containing factors for both sexes; one sex is homozygous for both these factors, the other is heterozygous for one of them and homozygous for the other. The factors are then weighted, in a manner not unlike that proposed by Spillman,¹ so that in one case femaleness, in the other maleness, come to expression. This formulation thus maintains the form of Mendelian inheritance, but contains elements of the quantitative theory of sex determination. The formula

¹ Spillman, W. J., *Amer. Nat.*, Vol. 44, 1910, pp. 214-228.

¹ *Proc. U. S. Nat. Mus.*, XXXVIII, 251, 1910.

applies as well to species in which the female is the heterozygous sex as to those in which the male is heterozygous. The author does not hesitate to locate these factors in the chromosomes (though only one of them is in the X-chromosomes), and he is at considerable pains to show how this representation may be in harmony with the facts regarding several well-known cases of sex-limited inheritance. Crossing over (Morgan) is a modification of the regular process, but in no wise a contradiction.

Chapter XIII. is largely new. It relates to polymery, interference of genetic factors, sterility of hybrids and coupling of factors. Breeders, especially in Germany, come in for some sharp criticism for not adopting Mendelian methods and terminology. Inheritance in man is discussed in the final chapter of the book, which is new, and an extensive list of literature appearing from 1911 to 1913 is added to the old bibliography.

Numerous other changes, both additions and emendations, are made elsewhere. Many of these are made for pedagogical reasons. Some are of interest as indicating possible changes of the author's opinion. Thus, the author is now more inclined than formerly to regard the mutability of *Oenothera lamarckiana* as due to the hybridity of that species. He now leans more to the "Presence and Absence" theory of Bateson as representing the real truth. The chapter on inheritance of acquired characters is clarified, but the author's views are apparently little changed.

In a growing subject a book can scarcely be without errors. Thus, the four armadillo embryos of a litter are still referred to the first four blastomeres of the egg, whereas the reasons for so regarding them seem to have disappeared in the work of Patterson.² Typographical errors are few. Unfortunately, several of these have crept into the illustrations, but attention is directed to them in the legend.

The book is so good, however, that one can overlook its few faults. The new edition is plainly an improvement over the old. One

could wish it were to be translated into English for the benefit of the American students who will not read it in the original.

A. FRANKLIN SHULL

Solvents, Oils, Gums, Waxes and Allied Substances. By FREDERIC S. HYDE, S.B. Consulting Chemist, New York. New York, Van Nostrand. 1913. Price \$2.00.

These notes are for the use of factory chemists who wish a book on the subjects named which shall be condensed and authoritative.

The title suggests one of the good features of the book, that which gives the solvents for many of the substances mentioned; besides this, however, methods are given for the analysis of these compounds. In attempting to cover such a wide field it is not surprising that inaccuracies have crept in. For example, the statement regarding the Maumené-Sherman test (with sulphuric acid) is in error, as no dilution of the oil is necessary when using the ninety per cent. acid. The general unreliability of the Valenta test is not clearly stated. It is to be regretted that the "saponification equivalent" is again revived as it is infrequently met with at present. It should be noted that the New York State Tester is not commonly used for the ordinary lubricating oil—the Cleveland Cup is the one commonly employed. In the analysis of paints no reference is made to the use of the convenient centrifuge.

The book is one which will be very useful to all having to do with these substances.

SPECIAL ARTICLES

ADAPTATION OF THE TAMARISK FOR DRY LANDS

ALTHOUGH a specialist in the line of cereal investigations, the writer has had occasion during the past ten years, in connection with grain experiments in dry-farming in the Great Plains and Western States, to observe the comparative adaptation to conditions of drought of various orchard and forest trees. While certain trees, such as the black and honey locusts, the elm, Osage orange, hack-

² Patterson, J. T., *Jour. Morph.*, Vol. 24, No. 4, 1913, pp. 559-662.

berry and Russian mulberry, are generally known to be adapted for dry-land farming, it is surprising to find that so little attention has been given to the tamarisk as a shrub, or small tree, suitable for hedges and shelter belts, though the experience of the writer has shown it to be absolutely unequaled for this purpose. Only four experiment stations at present come to mind where the tamarisk is grown at all, and, even in these places as a rule, only for ornament or as a curiosity. These are the New Mexico Experiment Station, the Hays Branch Experiment Station, in Kansas, the Arizona Experiment Station at Tucson, and the Fallon Experimental Farm on the Truckee-Carson Irrigation Project in Nevada. At the last named place, however, it is being employed experimentally and from a practical standpoint because of its qualities above mentioned.

It is peculiar that the tamarisk is listed by a number of nursery companies as an ornamental for the humid areas of eastern United States and is commonly employed in that way. Rarely is any mention made in nursery catalogues of its adaptability for dry-land conditions. The writer was made acquainted with its drought-resistant qualities accidentally through having obtained a single specimen for planting in a yard in the southwestern plains. It was soon found to be by far the most drought-resistant and otherwise hardy of all the trees and shrubs planted on the same land, including about twenty species. There appears to be no limit in dryness of the soil on any usual Great Plains' farm beyond which this plant will not survive. It is also best fitted for saline soils of all plants yet known to the writer. It has an extremely rapid growth, and, by branching out close to the ground, produces an excellent close hedge which will soon turn some kinds of stock even with its absence of thorns. None of the species known to the writer grow very tall, not ordinarily more than twenty feet, though two rather old specimens have been observed near the courthouse at Tascosa, Texas, 12 to 15 inches in diameter.

To the ordinary observer, not a specialist

in botany, the plant is best described by saying that it most resembles asparagus. It has a tendency to make a very scraggy growth and will not grow erect with the lower limbs very far from the ground unless carefully and constantly pruned to that end. Botanically it belongs to the order Tamariscineæ. It bears very small scale-like leaves and small pink or white flowers, which are either four or five parted.

On the land above mentioned, situated in the western portion of the Texas Panhandle, the writer has tried the method (also suggested by the editor of *The Oklahoma Farm Journal*) of dividing cultivated ground into narrow fields several times as long as broad, extending with their greatest dimensions east and west, and planting narrow belts of trees on the south sides of these fields to check the blowing of the soil, which method, so far, is found to be excellent. The trees employed in planting these belts were usually black locust, honey locust, Osage orange and Russian mulberry, but it is now the practise to plant tamarisk as the first row on the south side of each of these belts.

An interesting thing about tamarisk, and of the greatest importance where these trees are adapted and where nursery stock is not easily obtained, is the fact that the plant can be readily and rapidly propagated by means of cuttings. After two or three years' growth, therefore, of from one to one dozen specimens there need be no further purchase of stock, as there is then plenty of material in the way of cuttings from these trees for all ordinary planting purposes. If advantage is taken of an opportunity to put the cuttings in the ground just after a rain, no further attention is needed other than good cultivation, and during an average season on the driest farms in the Great Plains the trees will thereafter succeed without any question.

In the Kew Index there are listed about seventy species of tamarisk which are found in various parts of the world, but none are native in North America and, apparently, only a half dozen at most are found in Europe. Alfred Rehder has given a good account of the genus

in Bailey's "Cyclopedia of Horticulture." The plant seems particularly at home in northern Africa and in the immense semi-arid and desert region comprising the Aralo-Caspian district, Russian Turkestan, Arabia, Persia, etc. The following eleven species are listed by nurserymen in this country, but the accuracy of the names is not yet determined: *Tamarix Parviflora*, *T. Algerica*, *T. Amurensis*, *T. Odessana*, *T. Chinensis*, *T. Gallica* and variety *Indica*, *T. hispida* (= *T. Kashgarica*), *T. juniperina* (= *T. Japonica* and *T. plumosa*), *T. tetrandra* and *T. Germanica*. *T. Germanica* and eight or nine others are now, however, referred to *Myricaria*.

The most common species in cultivation in this country appear to be *T. parviflora* and *T. gallica*, the latter originating in southern France. Discussions on the tamarisk have commonly referred to it as being of African origin. For our Great Plains and the drier portions of the western states most likely the species of Siberian origin would be best adapted. Numerous specimens have been introduced into this country by the U. S. Department of Agriculture, chiefly from China and Chinese Turkestan.

It is very important not to confuse the tamarisk with the tamarack, an extremely different plant, adapted in fact to marshes.

These few notes on the above subject are offered with the hope that interest will be stimulated in much more extensive plantings of this remarkable drought-resistant and alkali-resistant shrub in the districts in this country where it is adapted.

SMITHSONIAN INSTITUTION,
WASHINGTON, D. C.

SOCIETIES AND ACADEMIES

BOTANICAL SOCIETY OF WASHINGTON

THE ninety-third regular meeting of the Botanical Society of Washington was held in the Assembly Hall of the Cosmos Club at 8 P.M., Tuesday, January 6, 1914, with 42 members and 5 guests present.

Application for membership of Messrs. H. Pitier, Arno Viehoever and Raymond B. Wileox were read. Messrs. Charles Thom, Charles S. Ridgway, George D. Clark, Clarence W. Carpenter, William A. Dayton, Orlo A. Pratt and Nathan R. Smith were elected to membership.

Mr. F. L. Lewton called attention to the discovery of the records of the Washington Botanical Club, the predecessor of this society from 1898-1902. He stated that these records were missing when the history of the society was written up a few years ago, and also gave a brief review of the club.

The scientific program was as follows:

The James River Hybrid Walnut: PETER BISSET.
(With lantern.)

Lantern slides were shown of a walnut tree on the Rowe Farm, on the James River, opposite Lower Brandon, Va. The tree is 100 ft. high, with a spread of 123 ft., although until a recent storm the spread was 134 ft. At 4 ft. from the ground the tree is 31 ft. 3 in. in circumference, and at 6 ft. from the ground is over 25 ft. in circumference. At 12 ft. from the ground it divides into four large branches, three of which are larger than any tree in the neighborhood. No one has any definite knowledge of the age of the tree, but as the old farmhouse was built about 200 years ago it is supposed that the seed was planted at that time. Its growth was probably rapid, judged from seedlings which attained a height of 5 ft. 10 in. in one season, as compared with 3 ft. in seedlings of *Juglans nigra* which grew beside them. A seedling planted nearby about 1860 is now 2½ ft. in diameter and of the height of the parent tree. The characters of the leaves and nuts are such as to suggest a possible hybrid origin. The pubescence of the branches and leaves agrees with *Juglans cinerea* and the fruit and other leaf characters suggest *Juglans regia* instead of *J. nigra*. The nuts are of low vitality and very thick shell.

Smeiter Injury in Southeastern Tennessee: DR. G. G. HEDGECOCK. (With lantern.)

To be published in the *Journal of the Washington Academy*.

Some Chinese Horticultural Brassica Species: DR.

D. N. SHOEMAKER. (With lantern.)

Horticultural forms of Chinese Brassicas in the United States at present are: Three well marked varieties of mustard, *Brassica juncea*. These are well established in the American seed trade. Four types of non-pungent brassicas, of uncertain specific relations: (1) The heading forms, Chinese name *Pai Taa*. These make long heads resting on the surface of the ground, and present many varieties. (2) A form with long broad petioles, and long light green leaf blades, the veins of which are quite prominent. (3) A form with very broad short flat petioles, and dark green leaf blades. These usually send up swollen seeding stems. (4) A very loose-leaved round petioled form, used by the Chinese as a summer vegetable.

THE ninety-fifth regular meeting of the society was held at the Play House on Tuesday evening, March 3, 1914, at eight o'clock, at which the retiring president, Dr. W. W. Stockberger, delivered an address on the social obligations of the botanist (to be published in SCIENCE).

The ninety-sixth regular meeting of the society was held at the Cosmos Club, Tuesday, April 7, 1914, at eight o'clock.

Messrs. Robert B. Whitney and H. S. Westover were unanimously elected to membership in this society.

The scientific program was as follows:

Professor A. S. Hitchcock reviewed (a) a paper by Trabut in which he states that the oats commonly cultivated in temperate regions descended from *Avena fatua*, the Algerian oat from *A. sterilis* and *A. strigosa* from *A. barbata*; (b) a paper by Schulz on the origin of wheat in which he states that *Triticum monococcum* descended from *T. ægilopoides*, *T. dicoccum* from *T. dicoccoides*, and *T. spelta* from an as yet undiscovered wild form; that the naked wheats are derived from the spelt wheats, *T. turgidum*, *T. durum* and *T. polonicum* from *T. dicoccum*, and *T. vulgare* and *T. compactum* from *T. spelta*.

Dr. H. L. Shantz reviewed a paper by Sir Francis Darwin.¹ A method by which the influence of stomatal adjustment on the rate of transpiration is eliminated. The stomata of the lower surface of the leaf are locked with cocoa butter or petrolatum and incisions made through the upper epider-

¹ *Proceedings of the Royal Society*, Series B, Vol. 87, February, 1914.

mis, thus connecting the intercellular spaces with the outer air. By this method transpiration was found to decrease proportionally as relative humidity increased. The straight line relation led to the conclusion that a relative humidity of 105 would be required to reduce transpiration to zero.

C. S. Scofield, "Chinese Wild Rice," with lantern (to be published later).

Dr. P. Spalding, "Present Status of the White Pine Blister Rust," with lantern (to be published as a bulletin of the Department of Agriculture).

R. Zon, "Meteorological Observations for Purposes of Botanical Geography, Agriculture and Forestry," with lantern.

The inadequacy of the present climatic data for the purposes of botanists lies not so much in the kind and character of observations that are being recorded as in the manner of their classification, their grouping and computing.

To properly understand plant life, it is essential to group meteorological data by actual periods of growth and rest. During each of these two periods plants react to temperature of the air in an altogether different way. The temperature records of the temperate region of the United States should be computed separately on the basis of the normal monthly mean not reduced to sea level for the period of rest or the period of growth, and in some localities also for a third period, the hot period. The period of rest should include all months having a normal mean temperature of 48° F. or less. The period of growth should be included, all months having a normal monthly temperature of from 50° to 72° F. The hot period in temperature latitudes should embrace months with a normal average temperature of more than 72° F.

A map showing localities with the same duration of the periods of growth and rest has been tentatively prepared.

Aside from monthly mean temperatures the average temperatures by periods of ten days (decades) are also desirable, and also the mean temperatures for periods when the ground is covered with snow and periods when the ground is bare. Similarly, the mean temperature for each period during which certain winds prevail.

Summation of temperatures, as suggested by Bussengo and de Candolle, do not indicate the actual requirements of plants for heat, since they overlook the existence of an optimum temperature for the development of each plant.

Groups of days with a given temperature are considered preferable, and the following classification is suggested:

1. *Freezing days*, with a daily average of 32° or less. These are further subdivided into: (a) Freezing days without thawing; (b) freezing days with thawing.

2. *Cold days*, with an average daily temperature ranging from 32° to 40° F. This group should be further divided into: (a) Days with frost; (b) days without frost.

3. *Cool days*, with an average daily temperature from 40.1 to 50° F. This group should be divided into: (a) Days with frost; (b) days without frost.

The paper discussed also the temperature of the soil, humidity of the air, precipitation, snow cover, soil moisture, sunshine and barometric pressure.

P. L. RICKER,

Corresponding Secretary

THE ST. LOUIS ACADEMY OF SCIENCE

"MOUNDS and Mound Builders" was the subject of a lecture by Dr. H. M. Whelpley, at the February 16 meeting. It was illustrated with lantern slides.

The lecture dealt particularly with the mounds of Illinois and Missouri. Strictly speaking, there was no race of mound builders, mounds having been built by primitive peoples, the world over. Indian mounds were discussed and their various types explained. The important Cahokia Group, in Madison Co., Ill., was considered in detail. The general arrangement and location of these mounds was clearly shown in a series of maps of the Long Lake, Bluff, Forest Park, St. Louis, Cahokia and other subgroups. It was shown that at the time these mounds were built, the Mississippi River probably was close to the Illinois bluffs, so that they were all originally on the west side of the stream, a fact which helps to explain their similarity. From their nature, it is evident that many years must have been required for construction and the archeological evidence points to their having been built by an agricultural people, quite different from the Cahokia Indians whom white men found here. Some views as to their possible use were considered. The plan of Monks', or better, Cahokia Mound was discussed and a number of early drawings and diagrams were thrown upon the screen. The known history of this mound was reviewed. Attention was called to the artistic possibilities of mounds and the agencies tending toward their destruction were emphasized. The speaker closed with a plea for the preservation of these wonderful relics of earlier ages.

G. O. JAMES,

Secretary

Western Reserve University

School of Medicine

In the City of Cleveland

Founded in 1843, admits only college men who have completed at least three years with the assurance of a degree; large individual opportunity; excellent laboratories; extraordinarily large clinical facilities with over 800 hospital beds and 100,000 dispensary visits in 1913; over 90 per cent of graduates of the past three years received hospital appointments; fifth optional year leading to A.M. in Medicine.

Next year opens October 1st, 1914

Closes June 17th, 1915

Tuition \$150.00

For catalogues or information address

The Secretary,

1353 East 9th St.

Cleveland, O.

New York Post-Graduate Medical School and Hospital

Department of the Laboratories

JONATHAN WRIGHT, M.D., Director

Courses of three weeks duration arranged for practitioners of medicine are offered in each of the four laboratories of

Pathology Bacteriology
Bio-Chemistry Tropical Medicine

Advanced courses and special courses are offered in the following subjects: Pathology, Bacteriology, Bio-chemistry, Serology and Vaccine Therapy, Pathological Chemistry and Toxicology, Haematology, Special Pathology, Protozoology, and Helminthology.

Special opportunities are offered to research workers in all the laboratories.

Write for schedule of courses and
for further information

GEORGE GRAY WARD, Jr., M.D.,

Secretary of the Faculty

303 E. 20th St.

New York City

Marine Biological Laboratory

Woods Hole, Mass.

INVESTIGATION

Entire Year

Facilities for research in Zoology, Embryology, Physiology and Botany. Seventy-six private laboratories, \$100 each for not over three months. Thirty tables are available for beginners in research who desire to work under the direction of members of the staff. The fee for such a table is \$50.00.

INSTRUCTION

July 1 to August 11,
1914

Courses of laboratory instruction with lectures are offered in Invertebrate Zoology, Embryology, Physiology, Morphology and Taxonomy of the Algae, Physiology and Ecology of Marine Strand and Bog Vegetation. Each course requires the full time of the student. Fee, \$50.00. A lecture course on the Philosophical Aspects of Biology and Allied Sciences is also offered.

SUPPLY DEPARTMENT

Open the Entire Year

Animals and plants, preserved, living, and in embryonic stages. Preserved material of all types of animals and of Algae, Fungi, Liverworts and Mosses furnished for classwork, or for the museum. Living material furnished in season as ordered. Price lists of Zoological and Botanical material sent on application. State which is desired. For price lists and all information regarding material, address

GEO. M. GRAY, Curator, Woods Hole, Mass

The annual announcement will be sent on application to The Director, Marine Biological Laboratory, Woods Hole Mass.

THE AMERICAN GEOGRAPHICAL SOCIETY OF NEW YORK

Broadway at 156th Street

Captain Koch's Crossing of Greenland. (Map.)

Joint Meeting of the American Geographical Society and

the Association of American Geographers.

Geographical Record. (A summary of exploration and

other current information.)

Book Reviews and Titles. (63 items.)

Current Geographical Papers. (174 bibliographical notes

on geographical literature in scientific periodicals

and reports.)

New Maps (Critical map reviews and a list of notable

new maps covering 135 items.)

The index to the BULLETIN for 1913 (117 pp.) contains over 9,000 references to the explorations, maps, books, papers and other geographical activities of the year. Price, 50 cents postpaid.

The Society is showing in its exhibition hall a collection of 277 photographs of Porto Rico, 31 of Bermuda, 54 of Constantinople and 59 of the most notable recent maps. Open from 10 A.M. to 5 P.M. on week days and from 2 to 5 P.M. on Sundays.

The Society's collections of geographical literature and maps are maintained for consultation by the public.

Fuel

Solid, Liquid, and Gaseous

By J. S. S. BRAME, F.C.S., Instructor in Chemistry, Royal Naval College, Greenwich, Lecturer on Fuel, Sir John Cass Technical Institute, Aldgate. With 73 Figures and 55 Tables.

8vo. Pp. xvi+372. \$3.50 net. (Weight, 34 oz.)

Endeavor has been made in this book to place before the technical man, who is not a fuel specialist, but who requires a good general knowledge of the subject, as full information on all fuels of importance as space permits: at the same time the scientific principles underlying gas producer practice, combustion, etc., have not been neglected. The application of fuels to other purposes has not been overlooked, but primarily fuels are considered in their relation to power. As far as possible the diagrams have been chosen to illustrate principles and typical forms of plant and apparatus.

Geological and Topographical Maps

Their Interpretation and Use: A Handbook for the Geologist and Civil Engineer

By ARTHUR P. DWERRYHOUSE, D.Sc., F.G.S., Lecturer in Geology in the Queen's University of Belfast. With 90 Figures and 2 Tables. 8vo. Pp. viii+133. \$1.25 net. (Weight, 18 oz.)

A text-book dealing with the practical problems which are involved in the interpretation of maps, descriptions and instructions that will enable the civil engineer and the student of geology to draw sections of the country depicted upon maps, and to ascertain the depths and thickness of the various strata of which it is built up, and their relations to the surface of the ground and to each other.

A brief summary of the main structural features of rocks is included, for the benefit of those unable to obtain a systematic course of instruction in geology.

Longmans, Green, & Co.

4th Ave. & 30th St., N. Y.

LEITZ NEW COMPARISON EYEPIECE

This Comparison eyepiece serves for comparing, by means of a simple ocular, two objects on the stages of two different microscopes arranged side by side. The usual type of microscope available in the laboratory may be utilized, and it is essential that only objectives of identical power and optical data are used.

Manipulation

Under one of the microscopes utilized, a normal (standard) specimen is placed while the other stand

Write for Literature 71 O.

Leitz Comparison Eyepiece, as described, \$36.

Unique in its construction. Of incomparable value.

holds the preparation to be compared, in order to determine if any coincidence in the specimens exists. The two images in the field are situated side by side, so that every microscopist will realize how reliable such a comparison is bound to be.

Construction

The ocular consists of a prism casing with two tubes attached thereto. These tubes slip into the draw-tubes of the two microscope stands.

Board of Health Departments, especially, compelled daily to investigate food and other preparations in order to determine if same comply with the Pure Food Act, will, in establishing a normal (standard) specimen, be in a position to make a proper analysis more readily and conveniently than heretofore.

We are confident that this new device of Comparison Ocular will assist greatly in proper microscopical analysis and certainly answers a long-felt demand.

ISOSTASY AND THE SIZE AND SHAPE OF THE EARTH¹

It is the speaker's desire, in this paper, to touch briefly on some phases of geodesy which should be of general interest to the physicist.

Geodesy is one of the oldest sciences; probably second in this respect to astronomy alone. What is the extent of the earth in the horizontal plane, to what depth does it extend, and what is on the other side are questions which must have been asked by men of the earliest times. The history of geodesy will have to be passed over, for lack of time, although it would be interesting to follow the accumulation of data as to the shape and size of the earth.

Before one can study efficiently the great geophysical facts and comprehend them, he must know the shape and size of the earth with considerable accuracy. For some time before the end of the seventeenth century, it was taken for granted that the earth was a true sphere.

The announcement by Newton in 1687 of his theory that the earth was an oblate spheroid added much interest to the subject of its exact shape.

A meridional arc of about $8\frac{1}{2}$ degrees, extending north and south of Paris, was measured by J. and D. Cassini between the years 1683 and 1716. The results of the first computations of this are indicated that the length of the degree was less at the northern than at the southern end. This gave to the earth the shape of a prolate spheroid. A great controversy arose over

¹ Read on December 30, 1913, before Section B of the American Association for the Advancement of Science, at Atlanta, Ga.

the question as to whether the earth has the form of an oblate or prolate spheroid, and to settle it the French Academy sent expeditions to Peru in 1735 and to Lapland the following year to measure arcs near the equator and within the arctic circle. The result of these measurements confirmed the theory of the oblate spheroid. A revision of the computations of the Paris arc also showed that the northern degrees were the longer, thus confirming the results obtained from the work done in Peru and Lapland.

The first near approach to the size of the earth resulted from triangulation done in the last decades of the eighteenth century to connect the observatories of Paris and Greenwich and to determine the length of the earth's meridian quadrant. For the latter purpose an arc of the meridian of nearly ten degrees was measured in France. One ten-millionth of the resulting length was adopted as the standard of length (the meter). Any other length could have been selected as the standard, for the meter bears no such exact relation to a quadrant as later and more accurate data show.

Geodesists were very active during the nineteenth century and will be for some time to come, in making geodetic measurements to determine the mean figure of the earth with greater and greater degrees of accuracy. There comes a time, for any one given area, when it is useless to add more geodetic data for the purpose of obtaining a more exact mean figure, for there are constant or systematic errors present in the data, the effect of which is probably much greater than that of the accidental errors.

But there is much to be gained by extending geodetic surveys to new areas and especially to new continents. (By geodetic survey is meant, here, triangulation and connected astronomic stations.) All of the

values of the earth's figure now available are the results of geodetic measurements in the northern hemisphere and, with the exception of India, the measurements have been confined to Europe and the United States. We may hope to get, before long, values for the figure of the earth from geodetic operations in South America and Africa, most of whose areas are below the equator, and Australia, all of which is in the southern hemisphere. It is believed that the mean figures resulting from accurate and extensive geodetic data in those continents will agree closely with the figures gotten from continents in the northern hemisphere. The geodetic surveys of the several nations on each continent should be connected and the reductions made on one spheroid and referred to a single initial position for each continent. Should this be done we shall be able eventually to compute a mean figure of the earth which will be of such great precision that it will satisfy the most exacting demands of science. The same spheroid and datum have already been adopted by Mexico, Canada and the United States.²

Coincident with the extension of geodetic surveys there will be carried on the computation of the geoid or the actual surface of the earth. This surface is probably so complex in shape that the work necessary to define it will have to be continued long after the satisfactory spheroid has been determined.

The geoid may be defined as that surface which coincides with the surface of the sea at rest. We can imagine an extension into the continents of an intricate network of sea-level canals. Then the surface of the oceans and the water in the canals would define the surface of the geoid. At some

² See news note in *Bulletin of the American Geographical Society*, August, 1913; page 614, on "The Adoption of the North American Datum."

points, probably not exactly at the sea shore, the mean figure of the earth—the spheroid—would intersect the actual sea surface, the geoid. Under the coastal plains the geoid would be slightly above the spheroid; while under great mountain ranges the geoid would be far above the spheroid, possibly as much as one hundred meters. Over the oceans the geoid would be under the spheroid surface by amounts varying directly with the depths of the water.

There is only one way to determine accurately the size of the earth, and that is by measurement on the continents of the lengths of arcs connecting points where the astronomic latitude and longitude have been determined. The measurements of such arcs may be direct, or they may be by means of triangulation. The earliest measurements were by the former method, but with the introduction of accurately graduated circles and the application of wires in the eye-pieces of telescopes, the indirect method came into general use.

At frequent intervals, in triangulation, the sides of some of the triangles in the scheme are accurately measured, in order to control the lengths. At the present time, this is done almost exclusively with nickel-steel (invar) tapes or wires. The probable accidental error of a measured length is seldom greater than about one part in one million. The constant error in such a measurement may be as great as one part in three hundred thousand. This accuracy is, however, far greater than that of the lengths of the triangle sides, as computed through the chain of triangles. The uncertainty of any one line between bases is about one part in one hundred thousand, on an average. A long arc, say one across a continent, can be measured with greater accuracy than that, for even the systematic and constant errors

of the various sections of the arc would probably act as accidental errors, and the greater portion of their effect would be eliminated.

The observations for latitude, longitude and azimuth, or direction, are made on the stars; and in the most refined work a correction is made for the variation of the pole.

One might think that the determination of the figure and size of the earth is a very simple process, consisting merely of obtaining by astronomic observations the accurate angular distances between each two of several points on a meridian, and then measuring accurately the linear distances between them. Three such points being sufficient to obtain the equation of the curve formed by the intersection of the meridional plane and the spheroid, the shape and size of the earth would be known. This would be true if the spheroid and the geoid coincided throughout, but, as stated above, they do not do so. The plumb line to which all astronomic observations are referred is, at each point, normal to the geoid, which is a very irregular surface and, therefore, very many astronomic stations must be established and used. The greater part of each of the differences between the astronomic positions, as actually observed, and the theoretical positions, based on an adopted smooth mean surface, must be treated as an accidental error. These differences reach a maximum value of about twenty-five seconds of arc (within the area of the United States) which is nearly one half mile. In the island of Porto Rico, the relative deflection between two astronomic stations, one at Ponce and the other at San Juan, was 56 seconds of arc, about one mile.

The shape, but not the size, of the earth may be determined from the observed value of gravity at stations widely distributed in latitude. But here again a few stations are

not sufficient, for the value of gravity does not follow any known definite law, owing to the disturbing influences of masses above sea level and the deficiency of mass in the oceans.

Helmert derived a formula in 1901 from the observed values of gravity at about 400 selected stations. This formula gives theoretical values which will agree well, on an average, with the observed values, but for any one station the difference may be large, even after one of the values has been corrected for the elevation of the station above sea level.

Helmert's formula, in the Potsdam system, is

$$\gamma_0 = 978.030 (1 + 0.005302 \sin^2 \phi - 0.000007 \sin^2 2\phi)$$

in which γ_0 , expressed in dynes, is the theoretical value at sea level in latitude ϕ .

It is evident that the difference between the theoretical and the observed values of gravity, and the deflections of the plumb line (which, as stated above, are the differences between the observed and the theoretical astronomic positions) are due to the disturbing influence of the topography and the effect of deviations from the normal densities in the earth's crust. The term "topography" is applied to the visible land masses and the deficiency of mass in the oceans. But when the attractions of the topography are applied as corrections, the differences may still be large, but of the opposite sign.

About sixty years ago Archdeacon Pratt of England arrived at the conclusion, from a study of the deflections in India, that there must be a deficiency of mass under the Himalayan Mountains and that the deficiency extended to a limited depth. The advancement of this theory marked an epoch in geodesy. From time to time, writers in different countries have elaborated on the mere statement of Pratt. But

it was Hayford who gave this theory a quantitative expression when, as a member of the United States Coast and Geodetic Survey, he corrected the astronomic latitudes, longitudes and azimuths in the United States for the effect of topography and its negative equivalent, called "isostatic compensation," when making two determinations of the figure of the earth.³

A preliminary report on the application of the theory of isostasy to the study of the deflections in the United States was made by Messrs. Tittmann and Hayford to the Fifteenth General Conference of the International Geodetic Association, held at Budapest, Austria-Hungary, in 1906.⁴

Isostasy was also considered by Hayford and the writer in reducing the gravity stations in the United States.⁵

In order that a clear idea of isostasy⁶ may be obtained, I shall quote Hayford:

If the earth were composed of homogeneous material, its figure of equilibrium, under the influence of gravitation and its own rotation, would be an ellipsoid of revolution.

The earth is composed of heterogeneous material which varies considerably in density. If this heterogeneous material were so arranged that its density at any point depended simply on the depth of that point below the surface, or, more accurately, if all the material lying at each equipotential surface (rotation considered) were of one density, a state of equilibrium would exist and there

³ "The Figure of the Earth and Isostasy from Measurements in the United States," by John F. Hayford, U. S. Coast and Geodetic Survey, 1909; "Supplementary Investigation in 1909 of the Figure of the Earth and Isostasy," by John F. Hayford, U. S. Coast and Geodetic Survey, 1910.

⁴ "Geodetic Operations in the United States, 1903-06."

⁵ "The Effect of Topography and Isostatic Compensation Upon the Intensity of Gravity," Spec. Pub. No. 10, U. S. Coast and Geodetic Survey, 1912, by John F. Hayford and William Bowie; same, second paper, by Wm. Bowie, 1912.

⁶ The term *isostasy* was first proposed by E. C. Dutton. See *Transactions of the Philosophical Society of Washington, D. C.*, Vol. XI, pp. 51-64.

would be no tendency toward a rearrangement of masses.

If the heterogeneous material composing the earth were not arranged in this manner at the outset, the stresses produced by gravity would tend to bring about such an arrangement; but as the material is not a perfect fluid, as it possesses considerable viscosity, at least near the surface, the rearrangement will be imperfect. In the partial rearrangement some stresses will still remain, different portions of the same horizontal stratum may have somewhat different densities, and the actual surface of the earth will be a slight departure from the ellipsoid of revolution in the sense that above each region of deficient density there will be a bulge or bump on the ellipsoid, and above each region of excessive density there will be a hollow, relatively speaking. The bumps on this supposed earth will be the mountains, the plateaus, the continents; and the hollows will be the oceans. The excess of material represented by that portion of the continent which is above sea-level will be compensated for by a defect of density in the underlying material. The continents will be floated, so to speak, because they are composed of relatively light material; and, similarly, the floor of the ocean will, on this supposed earth, be depressed because it is composed of unusually dense material. This particular condition of approximate equilibrium has been given the name *isostasy*.

The adjustment of the material toward this condition, which is produced in nature by the stresses due to gravity, may be called the *isostatic adjustment*.

The compensation of the excess of matter at the surface (continents) by the defect of density below, and of surface defect of matter (oceans) by excess of density below, may be called the *isostatic compensation*.

Let the depth within which the isostatic compensation is complete be called the *depth of compensation*. At and below this depth the condition as to stress of any element of mass is isostatic; that is, any element of mass is subject to equal pressures from all directions as if it were a portion of a perfect fluid. Above this depth, on the other hand, each element of mass is subject in general to different pressures in different directions—to stresses which tend to distort and to move it.

In terms of masses, densities and volumes, the conditions above the depth of compensation may be expressed as follows: The mass in any prismatic column which has for its base a unit area of the horizontal surface which lies at the depth of com-

pensation, for its edges vertical lines (lines of gravity) and for its upper limit the actual irregular surface of the earth (or the sea surface if the area in question is beneath the ocean) is the same as the mass in any other similar prismatic column having any other unit area of the same surface for its base. To make the illustration concrete, if the depth of compensation is 114 kilometers below sea level, any column extending down below sea level and having one square kilometer for its base has the same mass as any other such column. One such column, located under a mountainous region, may be three kilometers longer than another located under the sea coast. On the other hand, the solid portions of such a column under one of the deep parts of the ocean may be 5 kilometers shorter than the column at the coast. Yet, if isostatic compensation is complete at the depth of 114 kilometers, all three of these columns have the same mass. The water above the suboceanic column is understood to be included in this mass. The masses being equal and the lengths of the columns different, it follows that the mean density of the column beneath the mountainous region is three parts in 114 less than the mean density of the column under the sea coast. So, also, the mean density of the solid portion of the suboceanic column must be greater than the mean density of the sea-coast column, the excess being somewhat less than five parts in 114 on account of the sea water being virtually a part of the column.

This relation of the masses in various columns, and consequently of the densities, follows from the requirement of the definition of the expression "depth of compensation," that, at that depth, each element of mass is subject to equal pressure from all directions. In order that this may be true the vertical pressures, due to gravity, on the various units of area at that depth must be the same.

If this condition of equal pressure, that is of equal superimposed masses, is fully satisfied at a given depth the compensation is said to be complete at that depth. If there is a variation from equality of superimposed masses the differences may be taken as a measure of the degree of incompleteness of the compensation.

The investigations of the deflections and of gravity referred to seem to prove rather conclusively that in the United States a condition of isostasy exists. How perfect it may be, and what is the area of the cross-

section and the depth of the unit columns which are supposed to have equal masses, have not yet been accurately determined.

The depth of compensation is probably somewhere between one hundred and ten and one hundred and thirty kilometers.

It is reasonably certain that the compensation is not always complete nor always uniformly distributed to the depth of compensation. (The above statements are, of course, intended to apply only to the area of the United States. Later on a brief statement will be made in regard to the rather limited results obtained in the other countries.) But the average conditions in the United States indicate a close approximation to those postulated.

The application of isostasy reduced considerably the apparent anomalies, or deflections, in the United States and Hayford was able to compute a figure of the earth which is generally considered one of the best, and probably the very best, now existing. His dimensions⁷ are:

Equatorial radius, $6,378,388 \pm 18$ meters.

Polar semi-diameter, 6,356,909 meters.

Reciprocal of flattening, 297.0 ± 0.5 .

The application of isostasy to the reduction of the gravity observations has reduced the average anomaly in the United States to 0.018 dyne, and at only one station is the anomaly greater than 0.060 dyne. It is, therefore, now possible to compute a value for gravity at any point in this country with an uncertainty of 0.018 dyne. By either of the previous two generally used methods of reduction, in which isostasy was not employed, the average anomaly in the United States was much greater.⁸

⁷ See p. 54, "Supplemental Investigation in 1909 of the Figure of the Earth and Isostasy."

⁸ The average free air anomaly was 0.028 dyne and the average value of the Bouguer anomaly was 0.063 dyne.

The largest free air anomaly was 0.216 dyne and there were five other anomalies with values greater than 0.100 dyne. There were five Bouguer anomalies greater than 0.200 dyne and twenty-eight other anomalies greater than 0.100 dyne. It was found from the anomalies developed by the investigations of deflections and of gravity that there was no apparent relation between the topography and the size and sign of the anomalies nor between the anomalies and the areas of erosion or deposition. Some relations to the geological formation were developed.⁹

A severe test of the new method of reduction of gravity observations, with isostasy considered, was the determination of the flattening of the earth, from the stations in the United States alone. The resulting value is 1/298.4. This value agrees almost exactly with Helmert's value of 1/298.3 which resulted from a consideration of gravity stations widely scattered over the earth and with a great range in latitude. The anomalies by each of the older methods of reduction, in which isostasy is ignored, gave values which differed greatly from the generally accepted best values.

A brief statement of the method of making the gravity observations and of the accuracy attained will suffice. All of the stations in the United States used in the recent investigations had gravity determined by means of the quarter-meter invariable pendulum¹⁰ which makes an oscillation in approximately one half second. It is a modification of the pendulums devised by

⁹ See pp. 18-21 of "Effect of Topography and Isostatic Compensation upon the Intensity of Gravity" (second paper).

¹⁰ This pendulum and its case are described in App. 1, Report of the Superintendent of the Coast and Geodetic Survey for 1894, by G. R. Putnam. The method of obtaining the flexure of the case and the support is described in App. 6 of the Report for 1910, by W. H. Burger.

von Sterneck of Austria and first used by him about the year 1887.

The method employed is to determine the period of oscillation at a base station and then at the new station and from the relation between the two periods the difference in gravity between the two stations is determined. This is called the differential or relative method of determining gravity. The difference in gravity may be obtained with an accuracy represented by a possible error of about ± 0.0018 dyne, on an average.

The base station for the United States is at the office of the Coast and Geodetic Survey in Washington, D. C. The value for it was determined by the relative method, from the station at Potsdam, Germany, at which the absolute gravity had been determined from a long series of observations made with reversible pendulums.

It is difficult to determine the absolute gravity with a great precision, as is shown by the determination of the difference in gravity at Vienna and Potsdam, by the relative method. Each of these stations had its absolute value determined by many years of observations and each value was considered to be correct by an amount represented by a probable error of only a few thousandths of a dyne. The relative determination showed an error between them of 0.016 dyne.

Of course, the same constant error which may be present in the base station of a system will also be present at each station of that system determined by the relative method. Potsdam is now generally used as the base station for the world, although the values are also occasionally referred to the Vienna station. The values in the two systems will differ by 0.016 dyne.

A comparatively small error in the value of gravity at the base station of the system does not appreciably affect the flattening

of the earth, derived from the gravity data of the system.

The investigations made in the Coast and Geodetic Survey show that, on an average, the gravity anomalies and the unaccounted for residuals of the deflections of the vertical are small for the United States. They also show that the area of the United States as a whole is practically in a state of perfect isostatic equilibrium. But there are many places where the gravity anomalies and the deflections indicate departures from the state of equilibrium. It is very important that additional data may be gotten which will permit of a determination of the degree of deviation from the perfect state and of the horizontal extent of the affected regions.

In one of the illustrations¹¹ of the second report on the gravity investigations, which shows by contours the Hayford anomalies, the evidence would lead one to believe that the causes of the largest anomalies are confined to small areas. For instance, there is an anomaly at Washington of $+0.037$ dyne, while at Baltimore, only 40 miles distant, the anomaly is -0.011 dyne. At Seattle, the anomaly is -0.093 dyne, while at Olympia it is $+0.033$ dyne, and the distance between the two places is only about 50 miles. There are other cases of decided differences in the anomalies in short distances, and no doubt more will develop when additional gravity stations have been established.

The data shown in the illustration referred to lead to the conclusion that there is no extensive area in the United States which is very much under or over compensated. This is equivalent to saying that

¹¹ No. 2 of the "Effect of Topography and Isostatic Compensation upon the Intensity of Gravity" (second paper).

there is no large area which departs much from the perfect isostatic state.

It has been held by some¹² that the crust of the earth within the area of the United States is at all places in a state of perfect isostasy and that the gravity anomalies are caused by the investigators' erroneous distribution of the compensating deficiency of mass. This, no doubt, is true to a certain extent, but no rational distribution will account for the larger anomalies except upon the theory that there are local actual departures from the perfect isostatic state.

Earlier in this paper it was stated that there were developed some relations between the size and sign of the gravity anomalies and the geological formation. The stations established on the oldest rocks show an average anomaly of +0.024 dyne, that is they indicate too much mass in the earth's crust, while the most recent formations and the effusive and intrusive rocks give average negative anomalies which vary from -0.005 to -0.015 dyne. These show deficiencies of mass. It is not clear whether these anomalies are due to local deviations from the adopted mean surface density of the earth (2.67) or to actual departures from a state of complete isostasy.

The following table shows a summary of the gravity anomalies arranged in the several geological groups.

A stratum of material 100 feet in thickness, and of indefinite extent will cause an attraction of 0.0030 dyne. Therefore, the average anomaly 0.019 dyne would correspond to a stratum 630 feet in thickness. The average elevation of the United States is about 2,500 feet. Therefore, the isostatic compensation may be considered

Geologic Formation	Number of Stations			Mean Anomaly	
	All	With plus Anomalies	With minus Anomalies	With Regard to Sign	Without Regard to Sign
Archeozoic and Paleozoic.....	9	9	0	+0.024	0.024
Paleozoic.....	32	13	19	— .004	.019
Mesozoic.....	20	9	11	+ .001	.015
Cenozoic.....	33	15	17	— .007	.021
Effusive.....	8	2	6	— .005	.016
Intrusive.....	5	1	4	— .016	.018
Unclassified.....	16	10	6	+ .008	.020
All stations.....	123	59	63	— .001	.019

to be about 75 per cent. complete on an average for stations in this country. But the average gravity anomaly with regard to sign is 0.000 dyne, or nearly so, therefore it is safe to conclude that the area of the United States as a whole is in a state of perfect isostasy.

A more exact knowledge of the precise location with respect to depth of the compensating deficiency or excess of mass would be of very great interest and value. This is particularly true in the case of the areas where there are stations with large gravity anomalies. A preliminary study by the Survey will be made of this question in the near future. For this purpose the value of gravity and the deflections of the vertical in the vicinity of the anomalous areas will be used jointly. The preliminary studies may show whether much is to be expected from future investigations after much more gravity and deflection data are available.

An attempt will be made shortly to correct the deflections for the effect of the excesses and deficiencies of mass as shown by the gravity anomalies. It is possible that some of the unaccounted for portion of the deflections may be eliminated. The ideal condition would be to have only such residuals of the deflections as are caused by an error in the adopted figure of the earth, for then a new figure might be com-

¹² "Interpretation of Anomalies of Gravity," by Grove Karl Gilbert, Part C of Professional Paper 85, Contributions to General Geology, 1913, U. S. Geological Survey.

puted which would have far greater accuracy than any now existing.

The theory of isostasy has been applied in several other countries in the reduction of deflections and of gravity, but not to any great extent. In Switzerland the new method makes the observed and computed gravity agree more closely than do other methods which do not consider isostasy. In India the theory of isostasy has been applied and the preliminary results indicate that that country is not so completely compensated as is the United States.¹³ The complete reductions have not been made. Their results will be of world-wide interest and importance.

The reduction, by the new method, of all the gravity stations of the world should be made in order that additional data may be available for studying the distribution of the materials in the earth's crust in different parts of the world, and because the results would make it possible to compute a better shape of the earth. There is no necessity for delaying this reduction. Mr. Tittmann, the superintendent of the Coast and Geodetic Survey, in his report to the conference, at Hamburg, in 1912, of the International Geodetic Association, stated:

It is hoped that the International Geodetic Association in the near future may reduce all the available gravity stations of the world by this method, for it is reasonably certain that a value for the flattening of very great precision could be deduced from the results.

While each of the great nations and many of the smaller ones are making gravimetric surveys, yet there are many sections

of the globe which have very few or no gravity stations. Some great institutions may, in the not distant future, see the importance of a world-wide gravimetric survey and start out parties to make one.

The geodesist is in great need to-day of an apparatus for measuring gravity accurately on a vessel at sea. We have no accurate values over the vast ocean areas. Dr. Hecker's gravity determinations at sea, with the boiling point thermometer apparatus, are subject to uncertainties as large as the largest new method anomalies of gravity in the United States, that is, between 0.050 dyne and 0.100 dyne. Gravity at sea should have actual errors not greater than about 0.010 dyne.

Some of the geological questions may or may not be answered by a consideration of isostasy,¹⁴ but with isostasy an established fact, at least for large areas, the problems should not be as difficult as when various theories were held as to the degree of rigidity of the earth's crust.

One of the problems is as to the manner in which the earth's surface assumed an irregular shape. This is probably the most difficult one to answer. Of the theories proposed by a number of great men of science, none seems to be entirely satisfying. The theory of the unequal contraction of the outer layers of the earth during the change from the liquid to the solid state sounds reasonable until we consider that the thickness of the crust which could be affected is only about 70 miles, according to the theory of isostasy. There are extensive areas on land which average several miles in height. Also the great deeps in the oceans for considerable areas have average depths as great as four miles.

¹³ In a letter from Col. Burrard, published in *Nature*, May 8, 1913, he makes the statement: "Both the pendulum and plumb-line observers find the attraction of the Himalayas to be largely compensated, whilst the Windhyan Mountains are not compensated at all." It should be noted that the Himalayan range is about 4 miles in height, and the Windhyan range only 0.6 mile in height.

¹⁴ See "The Relations of Isostasy to Geodesy, Geophysics and Geology," by J. F. Hayford, *SCIENCE*, N. S., Vol. XXXIII, No. 841, pages 199-208, February 10, 1911.

It is impossible that the same materials could have densities differing by six parts in seventy, or nine per cent., due simply to unequal contraction from loss of heat. It is conceivable that the chemical elements of the earth's crust were the same everywhere before solidification, but they must have formed different chemical compounds in order to have had such different densities as must obtain in order to have the earth's crust in a state of equilibrium. The materials in the crust below the depth of 70 miles are assumed in the investigations to be in hydrostatic equilibrium and consequently they should have the same density in any layer at a given depth.

A theory, held by some, would make the depth of compensation a function of the elevation of the surface. The mountains would, according to this theory, have long roots of low density extending far down into the plastic materials, which are supposed to be below the seventy-mile depth. The investigations of the Coast and Geodetic Survey do not seem to substantiate this theory. If it were true we should have all of the crust under the continent of the same density down to a certain, unknown depth at which the plastic substrata began. The compensation would take place below that depth and it would consist in protuberances extending down into the plastic matter. The interior of the earth must be solid, but yielding to long-continued stress differences. Just how the depression of the sea bottoms is to be accounted for under this theory, the writer does not recall having heard. The crust there would probably have to be very thin.

A short article by Dr. P. G. Nutting,¹⁵ suggested to the writer a possible cause of

part of the elevation of the continents and the depression of the ocean beds. Let us assume that the surface of the earth, formerly at a high temperature, had cooled to a point below that of boiling water and that the surface was not level. Then the aqueous vapor would condense and fall in great quantities as rain and remain on the earth and flow to the lowest areas. This added mass would tend to produce an isostatic adjustment which would cause an undertow of material from the lower areas to the more elevated ones, with a resulting further depression of the low areas and elevation of the higher ones. How much effect this could have had is difficult or impossible to estimate. Of course, if there had been no irregularities in the earth's surface before the precipitation, the water would have covered the earth to a uniform depth.

The correct answer to another question would be of great value to several branches of science. The earth's crust, at least that part of it within the United States, may now be considered in a state of perfect isostatic equilibrium. But what was its condition in past geologic ages? It seems reasonable to suppose that the earth's crust was in the past in a state of isostatic equilibrium at least as perfect as at present, if it is assumed that the earth's crust is gradually getting cooler. With a high temperature the materials of the crust would have been more plastic than at present and should have yielded more readily to stress differences.

If we have now and always have had a condition of equilibrium in the earth's crust, can the recorded movements be explained on the isostatic theory?

The deflections and the pendulum observations show that the areas from which great masses of materials have been eroded are in equilibrium; also that areas within

¹⁵ "Isostasy, Oceanic Preepitiation and the Formation of Mountain Systems," *SCIENCE*, October 6, 1911.

which there have been great depositions are in isostatic equilibrium. We, therefore, must conclude that the mountains have been maintained for long ages at approximately the same elevation by an undertow of material toward them, while the areas of deposition maintain their depth in spite of the added material by a sinking due to the undertow from the crust under such areas. Consequently, the continent may be considered as not being leveled off as a result of erosion, but as kept at approximately the same general elevation.

While an isostatic adjustment by means of a transposition of material may account for the normal condition under the areas of erosion and deposition, it does not account for the great elevation, into mountains and plateaus, of rock which was once under the ocean. Evidently there must have been a change in the density, under such areas, and an expansion of the materials in the earth's crust to the extent indicated by the height of the topography above the sea. This change was not due to a mere expansion from change of temperature, as a bar would expand. The expansion of the crust must have been due to chemical or physical changes which made the elements present form compounds with densities differing from what they had been previously. What could cause such rearrangement as to change the density by several parts in one hundred is a problem for the geophysicist and geologist.

The fact that material which was once under the sea now forms a mountain range seems to disprove the "root of the mountain" theory of compensation. It is difficult or impossible to see how the crust with its surface at or below sea level (supposedly in isostatic equilibrium) could, in addition to expanding to form the mountains, also decrease its density in that portion far below the average depth of com-

pensation (122 kilometers). As a matter of fact, the deflections and the gravity observations indicate that the compensation is not deep down in the crust, but in general within the depth stated above.

The movements noted in the exposed earth's materials have been slow and were in most cases due to stress differences which were below the rupturing point of the rock. There has been much slow yielding, without fracture, to long-continued stress differences. The isostatic adjustment of the earth's materials in the upper crust after or during erosion might cause many of the movements that have been recorded in the strata.

In conclusion, the immediate work which the geodesists should perform is to reduce all the existing gravity stations of the world by the same method which should be based on a rational theory of isostasy. As opportunity permits, a gravimetric survey should be extended to new regions and especially to oceanic islands. And as soon as an apparatus is designed which may be used successfully on a vessel, an extensive gravimetric survey of the oceans should follow.

WILLIAM BOWIE

U. S. COAST AND GEODETIC SURVEY

SAFEGUARDING THE HEALTH OF COLLEGE STUDENTS¹

ATTENTION has frequently been called to the fact that many educational institutions fail to make adequate provision for safeguarding the health of their students. These criticisms find expression most often in connection with the report of the injury or death of a student who has been allowed to participate in athletics without proper medical supervision; or when some serious sanitary fault causes, or contributes to, an epidemic among the stu-

¹Based upon paper presented at Fourth International Congress on School of Hygiene, Buffalo, 1913.

dents; or there is unfavorable comment when some promising young student breaks down in course or shortly after graduation as a result of overwork or bad hygienic habits.

Many cases even more deserving of unfavorable criticism in which the student suffers avoidable physical damage and loss of time and money never come to light. These may be due to physical tendencies and handicaps that should have been discovered and warned against on examination, or to sicknesses that could have been avoided by better sanitation and control of living conditions. Four years of life in a college or university should mean for the average boy or girl a distinct gain in physical efficiency and in habits of sane, hygienic living instead of the opposite of these things, as is too often the case.

It is of course true that to-day nearly every institution of college rank is trying to make, or intends to make, some provision for protecting and promoting the health of its students. There has been a very marked change for the better in this respect during the past few years, and a wider recognition of the practical importance of measures that tend to keep the student in good health. Too often, however, the provision made consists merely of a gymnasium and facilities for competitive athletics, the use of which as well as the time and energy of the teachers are mainly limited to that small percentage of the student body who are candidates for the teams; and in connection with which there is no well-considered plan for bringing these and other agencies in the institution into a harmonious relationship for effective work in promoting health and efficiency.

It is not probable that any system of health supervision, however carefully devised and administered, can entirely prevent the occurrence of sickness or accident among the students. There can be no question, however, that much more should be done than is being done or even considered, in the majority of colleges and universities in the country, to limit the amount of preventable sickness and to increase the working efficiency of the students; nor can there be any question of the real and perma-

nent value of such preventive and educational work for both the individual and the community of which he becomes a part. The formulation of an adequate plan for health supervision must be based upon a consideration of the factors affecting student health in the college community. Such a study will suggest the division of these factors into two groups. In the first group will fall those factors that may be classed as "environmental," *e. g.*,

1. General sanitary condition of the neighborhood such as drainage, sewage disposal, breeding places for flies and mosquitoes.

2. Food and water supply in commons and boarding houses.

3. Sanitary conditions of rooms in dormitories and lodging houses as regards baths, toilets, janitor service and general surroundings.

4. Provision for advice and treatment in dispensary or infirmary in case of sickness.

5. Opportunities for exercise and recreation.

The second group will include the "individual factors," such as:

1. Physical characteristics and tendencies to weakness.

2. Knowledge and practise of the essentials of personal hygiene.

3. Habits of exercise and recreation.

This grouping serves at Princeton University as a logical basis for the division of responsibility for the supervision of student health between two closely allied bodies: The sanitary committee and the department of hygiene and physical education.

The sanitary committee is composed of six men appointed from the board of trustees and the university faculty, one of whom is a member of the department of hygiene and physical education. It has the responsibility for the administration of those factors which I have called "environmental." It maintains a close supervision over the administration of the commons and the infirmary; it employs the university physician, and has periodical inspections made of those lodging and boarding houses used by students for whom—about 15 per cent.—there is at present no provision on

the campus. It is also advisory to the board of trustees on such questions as:

1. Plans for modern sewage disposal plant.
2. The installation of a milk-pasteurizing plant in the commons.
3. Plans for a new infirmary, and a study of the sanitary features of plans for new buildings.

The administration of the second group of factors, those relating to the individual himself, falls to the department of hygiene and physical education. This department is organized and equipped to fulfill the following functions:

1. To conduct a regular academic course in hygiene, which is required of all freshmen one hour a week throughout the year.
2. To make thorough medical examination of all freshman at the beginning and the end of the year, and of all candidates for competitive teams at the beginning of each season, or more frequently in special cases.
3. To conduct classes in physical education, which is required of all freshmen three periods a week throughout the year.
4. To provide opportunities for exercise and the necessary instructions in voluntary work by upper classmen.
5. To encourage participation in intramural games and competitions by those who are not candidates for the regular university teams.
6. To stimulate the development of habits of hygienic living and of outdoor exercise and recreation among the whole student body.

Since the health interests of the university are closely bound up with those of the town, a natural and harmonious relationship has grown up between these two parts of the community for the promotion of the interests of general health. The active bodies in this work are the university sanitary committee and the borough board of health with its health officer. This board is composed of seven men, three of whom are members of the university. The president of the board is also chairman of the university sanitary committee, thus providing an opportunity for the closest cooperation between the two bodies. The effectiveness of this relationship is shown in the measures

that are put in force by joint action to improve the sanitary conditions in the community at commencement time, when there are many reunion headquarters temporarily established throughout the town; and at the time of the big games when there is an influx of from 20,000 to 30,000 people with the consequent strain upon sanitary provisions. The university contributes towards the salary of the health officer, so his services are available, under the direction of the sanitary committee, for the inspection of boarding and lodging houses occupied by students; for the periodical examination of the milk supplied to the commons and of the water in the university swimming pool; and for the technical supervision of the sanitary condition of grounds and buildings. The close relationship existing among these three bodies, the board of health, the sanitary committee, and the department of hygiene, makes possible an effective cooperation which results in an economical and efficient administration of the health problems of the entire community.

A university in a small town like Princeton which has a population aside from the university community of about 5,000 presents a simple problem from the point of view of health protection as compared with an institution located in a large city. It may be impossible to work out such an organization as this that we have been considering in every college town; but the general principle of establishing some comprehensive and effective plan of health administration should be put into effect in every large institution. A brief discussion of some of the essential phases of the plan as outlined may be of use in giving a clearer view of the work.

The supervision of the Princeton University infirmary is a function of the sanitary committee. The infirmary is in charge of an infirmarian, who is assisted by the necessary nursing and housekeeping force. The building contains fifteen beds and was built nearly twenty years ago. An isolation ward of about the same size was added later. A well-equipped dispensary adds greatly to the usefulness of the infirmary. Plans for a new in-

firmary are practically completed, as the present building is sometimes taxed to its utmost. The university physician is employed by the sanitary committee and attends the infirmary three hours daily, during the early morning and the late afternoon. Students are admitted upon his certificate and attended by him. A student may be attended by a physician from the town who is approved by the sanitary committee; and physicians and surgeons may be called in consultation if necessary.

Students are charged \$7 a year infirmary fees, which cover all necessary expenses during their stay in the infirmary. In contagious cases, or cases requiring special nursing the expense of the additional nurse is charged to the student. As board bills are charged to all students on their regular term bills the infirmary is credited with the amount of board the student would ordinarily pay during such time he may be confined to the infirmary. During the past year there were 400 bed cases, and about 4,500 dispensary calls. These figures may seem large for a student body of only 1,500, but much of the service in the dispensary, and even among the bed cases is in a measure preventive. For example, a boy with an incipient cold may be put to bed over Saturday and Sunday, and so a more serious illness and a further loss of time prevented.

In case a student is confined to his room by sickness that fact is reported to the college office before 10:30 by the janitor or the lodging house mistress, together with a statement whether or not a physician has been called. This early report gives an opportunity for word to be sent to the university physician, so that he can visit the student before noon if he has not secured medical attendance. No sick student is allowed to remain in his room in a dormitory more than a day. He is promptly taken to the infirmary, where he is given medical attention and nurses' care.

The inspection of the lodging and boarding houses is done regularly and a report is made on a form provided for the purpose. The points investigated include among others a statement as to the kind of house, the kind of room, the provisions for heating, lighting

and ventilation, the bath-room provisions, and the general character and tone of the place and people. In the case of boarding houses additional information is gained regarding the sanitary conditions of the dining-room, the kitchen, the refrigerator, care in garbage disposal, and notes on the general surroundings, such as the proximity of stables, chicken yards, exposed garbage, etc. Repeated inspections are made at irregular intervals during the year. Any defects are reported to the secretary of the sanitary committee who serves notice upon the owners of the premises. If the recommendations are not complied with promptly, the students are ordered out of the premises. The knowledge that such action will be taken by the university authorities and the fact that all payments for board and rent are made through the university treasurer's office, have had the effect of forcing the owners to keep the premises in proper condition.

A comprehensive physical examination is conducted by the department of hygiene and physical education. Special emphasis is laid upon the determination of the functional condition of the eyes, ears, nose, throat and the vital organs. The information so obtained serves as a basis for advice as to special exercises if needed. Advantage is taken of the opportunity to discuss with each individual the various practices and habits that affect his mental and physical efficiency. A follow-up scheme has been devised which makes it possible to keep in touch with special cases at regular intervals during the year and to cases referred to the home physician.

The course in personal hygiene deals with the fundamentals of health and physical efficiency; the influence of diet, exercise, bathing, etc.; the effects of personal habits, as the use of tobacco and alcohol; sex hygiene; and a study of the more common infectious diseases, their nature, cause, methods of transmission and prevention. Emphasis is laid upon the practical points of daily life, upon inducing the students to adopt a hygienic method of living, and upon the fact that health is in a very large measure subject to control.

A good deal of emphasis is placed upon the effort to promote the formation of habits of outdoor exercise and recreation among the upper classmen. This is done by organizing classes for voluntary work in various branches of physical education and by encouraging the organization of teams for athletic competition. In the development of these intra-mural athletic activities, advantage is taken of every natural student division as a basis for the organization of teams, with the result that there were during the past year 145 organized teams playing regular schedules for the championships of various groups; and throughout the year there were more than 1,300 men, counting the duplications on various teams during the different seasons, and not counting those who were on the various varsity squads, who took part in these contests. Competitions were conducted in swimming, water polo, relay racing, rowing, basket ball and baseball. The above statement does not include the large number of students who take part in individual contests in boxing, wrestling, tennis, golf and swimming.

This plan of guarding and promoting student health has been developed under the stimulus of the conviction that an educational institution has a real responsibility for the physical welfare of its students; that health is an educational factor of prime importance; that a student not entirely well is working under a handicap and is lowering the efficiency of the institution; and that a healthy body is one of the first essentials of clear thinking, clean living and efficient citizenship.

JOSEPH E. RAYCROFT

PRINCETON UNIVERSITY

THE GOVERNMENT OF LEARNED SOCIETIES

In connection with the work of a committee of the American Psychological Association I wrote a year ago to the secretaries of all the "learned societies" listed in the World Almanac asking how their officers were elected and whether the method was satisfactory. With very great courtesy almost every secretary answered my first question (though one or two

copies of constitutions failed to reach me), and most of them answered the second. The result is that I find myself with an amount of material which it seems well worth while to put together in print.

The sixty-eight "learned societies" here listed can be divided according to their method of electing officers into some nine groups, as follows.

Group A.—In the following associations officers are elected by the governing board.

American Academy of Political and Social Science. Officers are elected by (9) directors, one third of whom are elected annually to serve three years.

American Antiquarian Society.

American Association for the Advancement of Science. Officers are elected from fellows by general committee, which consists of council plus one fellow or member elected by each section. Council consists of certain present and past officers, fellows elected by sections and affiliated societies, and nine fellows elected by the council. Permanent secretary, secretaries of sections and treasurer hold office for five years.

Archæological Institute of America. Officers are elected by council, which is composed of general officers and delegates from local affiliated societies. Executive committee is partly ex-officio, partly elected by council at annual meeting.

American Numismatic Society. Council elects officers. Members of council are nominated from the floor and elected by ballot.

National Association for the Study and Prevention of Tuberculosis. Officers are elected annually by board of sixty directors on nomination of committee appointed by chair. One fifth of directors are elected at each annual meeting.

National Geographic Society. Managers elect officers. Eight of the twenty-four managers are elected at each annual meeting to serve three years. A majority of the votes cast is necessary for election.

New York Zoological Society. Officers and executive committee are elected by managers. Executive committee appoints a nominating

committee which prepares and posts nominations to replace the outgoing class of board of managers. Members vote on these at annual meeting.

Group B.—In the following associations nominations for office are made by the governing board at the annual meeting. Usually the rule permits other nominations to be made from the floor, though they are not often made. It is not always clear whether or not the official nominations include positions on the governing board itself.

American Association of Obstetricians and Gynecologists.

American Association of Pathologists and Bacteriologists. Rule includes all nominations. Council member serves seven years.

American Bar Association. Officers nominated by general council, which consists of one member from each state.

American Geographical Society of New York. Rule includes all nominations, but nine or more fellows can also nominate.

American Ophthalmological Society.

American Pediatric Society.

American Proctological Society.

American Psychological Association. Rule includes nominations for council.

American Therapeutic Society.

Society of Chemical Industry, New York Section. Committee nominates chairman, secretary and treasurer. Ten or more members can nominate ordinary member of committee. If there are not enough nominations committee completes list and there is no election. Five members of committee retire annually, three of whom shall be those who have made the fewest attendances at committee meetings.

Southern Medical Association.

The advantages claimed for this method of close control by the governing board are that it is less dangerous than off-hand nominations from the floor, facilitates business, has worked perfectly, allows meetings to be devoted to science exclusively. Eight secretaries commented on it favorably. In a ninth association a considerable number of members felt that it was unnecessarily oligarchical. Another objection is that it has occasionally been embarrassing

to have a small governing body called upon to choose between two or more of its own members for the presidency. This objection would not hold in the case of an association whose governing board is composed largely of ex-presidents.

Group C.—In the three following associations nominations for office are made by a nominating committee which is itself a more or less permanent body. The election takes place at annual meeting.

American Gynecological Society. Nominating committee consists of all ex-presidents at meeting. Two nominations are made for each office.

Society for the Promotion of Engineering Education. Nominating committee consists of the past presidents and the seven elective members of the council retiring the following year, but the president may add enough to bring members present up to five.

American Philological Association. Each year the chair nominates one new member of the nominating committee to serve five years.

It is claimed on behalf of this method that it ensures continuity and causes less unfavorable comment than random nominations from the floor.

D.—In the American Society of Civil Engineers the membership is divided into seven geographical districts, each of which is represented by two members of the nominating committee, one elected each year to serve two years, and the five latest past presidents who are alive. The secretary is appointed by the board. The method appears to be satisfactory, though it is possible under it for men to be elected to the nominating committee who are not familiar with the work of the association.

Group E.—In the following associations a nominating committee is appointed annually by the governing body. Elections are at annual meeting.

American Historical Association. It is said that years ago this association tried and abandoned something like a preferential primary.

American Library Association. Nominating committee appointed by executive board from persons not on board. Board adopts report

and prints names on the official ballot. Others may be added on petition, with consent of nominee. Council is partly self-perpetuating.

Group F.—In the following associations a nominating committee is appointed annually by the chair, though in the cases indicated it is simply said that it is "appointed." The committee reports, and officers are elected at the meeting.

American Academy of Medicine. "Appointed."

American Association of Anatomists. "Appointed." Officers elected for two years, secretary for four. Executive committee of eleven.

American Climatological Association. Usually consists of ex-presidents.

American Dialect Society. Nominating committee is "appointed" at the annual meeting, receives suggestions as to who is willing to serve, and reports in a few minutes.

American Economic Association. "Appointed." Usually consists of ex-presidents if enough are present.

American Fisheries Society.

American Forestry Association. "Appointed."

American-Irish Historical Society.

American-Jewish Historical Society.

American Laryngological Association.

American Laryngological, Rhinological and Otological Society.

American Medico-Psychological Association.

American Oriental Society.

American Otological Society. Nominations by business committee of three appointed by president for that meeting.

American Roentgen Ray Society. "Nominees are then voted upon by the Society" (two tickets?). It has been recently arranged in the interest of democracy that the new member of the executive committee be elected by ballot.

American Society of Naturalists.

American Sociological Society. Executive committee is partly elected, partly made up of former presidents. Practise has been to keep the same group of officers for a period of two years.

American Statistical Association.

American Surgical Association.

The secretaries of every one of these nineteen associations commented on their method of electing officers. One of them said no fault had ever been found with the method, though ambitious people were sometimes disappointed in the results. A second said that for twenty years the method had been found satisfactory, but that during the last year it had been claimed that such nominations may reflect the views of an extremely limited portion of the association instead of voicing the general desire. The remaining seventeen said without qualification that it worked well: "the ticket is always elected," "the secretary casts a ballot and there is never a grumble." The following statement, however, may not seem very satisfactory to extreme democrats: "The association is usually very harmonious at its annual meetings, and a small group of people have for some years practically prepared the slate. I think this is practically the custom with all similar organizations, and I believe it rarely happens that there is any controversy in regard to the matter."

Group G.—In the four following associations the nominating committee is chosen more democratically. Officers are elected at annual meeting.

In the American Microscopical Society and in the American Orthopedic Association the nominating committee is elected at a business meeting.

In the American Urological Association members of the nominating committee are selected by and from the various members of the several Sections present at the annual meeting.

In the Medical Association of the Southwest the nominating committee is composed of five members from each of the five states composing the association.

All four of these associations seem to be satisfied with their methods.

Group H.—In the following associations officers are elected by members present at the annual meeting, but there appears to be no nominating committee.

In the National Academy of Sciences officers

are elected by vote of the members present at the annual meeting. There is nothing in the constitution about their nomination.

In the American Dermatological Association officers are nominated on the first day of the annual meeting and elected on the second.

In the American Institute of Architects officers are elected by ballot of the delegates at the annual convention.

In the American Medical Association nominations are from the floor. Majority of votes cast is necessary for election.

In the American Entomological Society officers are nominated at the meeting before the annual meeting. The nominations are not restricted in any way and there is no nominating committee.

In the Actuarial Society of America officers are elected at the annual meeting without any nominations being made. Previous to the meeting, however, there is a straw ballot for members of the council, every fellow voting for two candidates for each vacancy. The result of this straw ballot is announced before the election, but it does not bind anybody.

In the American Ornithologists' Union an informal ballot is taken at the annual meeting and its result is announced before the first formal ballot is taken.

In the American Institute of Homeopathy any ten members at annual meeting can nominate. If no one gets a majority at first election there is a second vote confined to two highest candidates. It has been ruled that members nominated for an office can not withdraw their names.

In the American Association of Public Accountants officers are elected by delegates and fellows at large at the annual convention. Secretary is elected annually by trustees.

In the American Philosophical Society held at Philadelphia for Promoting Useful Knowledge officers are elected on the first Friday of January and the polls are open between the hours of two and five in the afternoon. Nominations must be made at the stated meeting next previous to the day of election; but if there should occur a failure of qualified candidates so nominated others not so nominated may be elected.

Group I.—In all the following associations the business of nominating and electing officers is conducted largely through the mails.

In the Geological Society of America the council prepares the regular ticket, and this is mailed to the members at least nine months before the annual meeting. Any five members may forward other nominations to the secretary. Such nominations are printed together with the names of the nominators as special tickets. The regular and special tickets are then mailed to the fellows at least twenty-five days in advance of the annual meeting. Balloting is then done by the use of two envelopes, of which one, the inner envelope, bears a legend indicating that it is a ballot; the outer envelope bears the voter's name, and before it is opened the secretary looks up the records to see whether the man is entitled to vote or not.

In the American Mathematical Society the council nominates at the October meeting through a committee usually composed of ex-presidents and ex-vice-presidents. Nominations are printed on a ballot with blank spaces for other names, and mailed to members, who may vote by mail or in person at the December meeting.

In the American Nature Study Society the council nominates one or more candidates for each office and members vote by mail or in person.

In the American Public Health Association the council nominates officers and submits ticket to the whole association for their vote. Council represents different states and federal departments.

In the American Society of Mechanical Engineers the president appoints a nominating committee, and any group of twenty or more members entitled to vote may constitute themselves a special nominating committee. Names of nominees and their nominators are mailed to members on an official ballot, together with an inner and an outer envelope, as with the geologists. A simple plurality of votes elects. Method is said to be perfectly satisfactory.

In the American Institute of Electrical Engineers the method pursued up to 1911 was as follows. Nominating blanks were mailed to the entire membership. After the forms

were returned and canvassed the directors prepared a "directors' ticket." This ticket, together with a statement of the votes received by all the candidates who had received not less than 3 per cent. of the entire number of votes cast, was issued to the membership. Members could vote for any one whose name appeared on this blank. The directors' ticket was always elected, as the vote against any one upon it would be scattering. For geographical considerations the directors did not always select the candidates who had received the largest number of nomination votes. The principal objections to this method appear in the *Proceedings* for January, 1912. They are these. There is no official way by which a group of members who desire to recommend a certain candidate can make their wishes known to the entire membership. Members can not usually tell whether a man they think of nominating is willing to accept. The scattering vote is increasing each year. The only way to suggest candidates is by circular letters, which become a nuisance. Not more than 20 per cent. of the members fill out nomination forms; so that a man with a very small vote can get on the directors' ticket and be elected. The new rule provides that on petition of fifty members a man's name may be printed on the nominating blank as a candidate for nomination. This results in a larger and more concentrated vote.

In 1912 the American Institute of Mining Engineers was practically changing its entire management. Under the old rule there was a board of directors and a council. Nominations for members of the council could be sent to the secretary, who mailed to the members a list of all nominations for each office so received, together with the names of persons ineligible for election to each office; and if the council or a committee thereof should have recommended any nomination, such recommendation was sent also. The new method recommended by a special committee resembles that of the American Society of Civil Engineers.

In the American Chemical Society members mail preference for president and four coun-

cilors. Council elects president from the four having the largest number of nominating ballots. For council the highest eight are considered nominated, and names mailed to members. Usual double envelopes for secrecy. Nine directors are elected by letter ballot of the entire (102) council. The directors are now the governing body, as council has grown too large.

In the Astronomical and Astrophysical Society of America members were nominated by mail and the three with the largest number of nominating votes were voted upon by members present at annual meeting. In case of a plurality of names in third place all were included in list to be voted upon. Plurality elected. The method had not proved entirely satisfactory, and a committee had been appointed to consider its revision.

In the Botanical Society of America individual members nominate by mail. The council then sees that there is at least one nomination for every office. Members vote by mail. Plurality elects. A recent rule empowers the secretary to eliminate the names of all nominees but the three receiving the highest number of nominating votes. Yet sometimes ten or a dozen receive the same number and have to appear on the final ballot mailed to members. Another possible objection to this method is that a few members of the association in one of the large universities can easily put a set of names in nomination by concentrating upon them when other nominating votes are scattered.

The conclusions which I am disposed to draw from the material at my disposal are as follows: A governing board of some kind is indispensable, and it is wise to follow the usual practise of electing a given proportion of its members every year for a term of years. If there is much work to be done by the secretary, he should be nominated either by a permanent nominating committee or by the governing board. If he accepts remuneration for his services he should be nominated or appointed by the board.

It is not usually wise to try to elect members of the governing board or other officers

without the aid of the board or some other committee, and it is distinctly unwise to do so if nominations are made through the mails.

If the board or a special committee is to act at all on nominations it seems better for it to nominate in the first place than to act on haphazard nominations afterwards. If the board itself nominates there is no reason why it should not send ample notice of its ticket to all the members of the association. In the absence of such notice it is not usually desirable that the board should nominate its own future members; for reasonable continuity in the management of an association is sufficiently insured by changing only a part of the board at a time, and the action of a series of nominating committees appointed from year to year by retiring presidents is less likely to cause continued irritation to a section of the association than the corresponding action of a practically self-perpetuating board.

If an official slate is unsatisfactory there is more chance to break it under a rule allowing other nominations to be made by groups of a certain size than under one allowing them to be made by single individuals.

No plan of election by members present at the annual meeting has been shown to be better than the common one of allowing the retiring president to appoint a nominating committee.

If an association exists for the sake of its meetings and does not attempt in any way to regulate the practise of a profession, it is questionable how far its machinery should be complicated for the sake of giving those who do not attend the meetings a voice in its management.

H. AUSTIN AIKINS

WESTERN RESERVE UNIVERSITY

STANFORD UNIVERSITY

THE trustees of Stanford University have increased the president's budget for the academic year of 1914-15 by approximately \$75,000 over that of the present year, which was about \$475,000. Of the increase, \$33,370 is for additions to the salaries of the present mem-

bers of the faculty, and \$20,000 for an addition to the usual allotment for departmental equipment. Ten thousand dollars of the increase to the budget is for the maintenance of the university's memorial church, which upon the completion of rebuilding since the earthquake has been placed under the president's direction. The salary increases have been apportioned among the ranks in the teaching force as follows: professors, \$11,950; associate professors, \$6,350; assistant professors, \$10,700; instructors, \$4,370. The trustees also announce a number of new buildings to be added to the university plant. These include, for the medical school in San Francisco, the remodeling of the main hospital building and the addition immediately of a new wing practically doubling the capacity of that building, and later the erection of a new women's building; and on the campus at Palo Alto a new library building, a new gymnasium for men and a new museum building. The library building, preliminary plans for which are being drawn, based upon suggestions by Librarian G. T. Clark, who has recently visited new college libraries in various parts of the country, will with the new museum form the front of a new quadrangle approximately of the same size as the present main quadrangle of the university, which is not quite 900 feet long, and will lie just east of it. The museum will not be undertaken for two or three years. The present museum is about a quarter of a mile from the main quadrangle, and President Branner in his inaugural address, urging the educational value of beauty, declared that the art collections here are practically inaccessible to the average student. In this same connection, and following the president's suggestion in the same address, the trustees are working out a comprehensive scheme of landscape gardening for the beautification of the university grounds. The salary and equipment increases and the new building announcements are in fulfilment of a statement published a year ago by the Stanford trustees, in which they declared that the resources of the university will in the future justify an increase in the annual allotment for academic

purposes, and that with the collaboration of Chancellor Jordan and President Branner, they had determined to build up the present departments of university work to the highest point of efficiency before entering new fields. The salary increases, it is announced, are the first of several to be made with the intention of raising the pay of the teaching force to a level somewhat nearer than it has been to that reached by the cost of living.

FOREIGN STUDENTS AT AMERICAN COLLEGES AND UNIVERSITIES

THERE were 4,222 foreign students in attendance at colleges and universities in the United States in the year 1913, according to figures just compiled at the United States Bureau of Education. This is an increase of 577 in two years. These students are not concentrated at the larger and better known institutions, as might be expected, but are distributed over 275 different colleges, universities and schools of technology. The number given includes only regular students of college or graduate grade; if students enrolled in preparatory departments, short-term courses, summer schools and independent professional schools were included, the total would be very much larger.

Canada has the largest representation—653 students. China and Japan are not far behind—there were 594 Chinese students and 336 from Japan attending colleges in the United States in 1913. Of the other Oriental or Asiatic peoples, India is represented by 162 students; Turkey by 143; Korea by 13; Persia by 21, and Siam by 13.

Latin-America is strongly represented. Cuba sends 209; Costa Rica, 29; Guatemala, 15; Honduras, 12; Nicaragua, 18; Panama, 28, and Salvador, 19. Mexico heads the list with 223 students. From South America, Argentine sends 43 students; Brazil, 113; Bolivia, 3; Chile, 12; Colombia, 37; Ecuador, 16; Paraguay, 2; Peru, 25; Uruguay, 2, and Venezuela, 7.

Abundance of higher education opportunities in the British Isles and on the continent of Europe has not prevented nearly 800 Euro-

pean students from coming to America to go to college. Great Britain and Ireland are represented by 212 students, and Germany, herself the mecca of the studious, sends 122. The others, in order of numbers, are: Russia, 124; France, 45; Sweden, 41; Italy, 38; Austria-Hungary, 34; Switzerland, 29; Norway, 26; Greece, 22; Spain, 20; Netherlands, 19; Bulgaria, 15; Roumania, 6; Belgium, 4; Portugal, 3; Montenegro, 1.

Even Australia and Africa have students at colleges in the United States. There are 56 students from New Zealand. Africa is represented by 15 from Egypt; 2 from Liberia, and 44 from South Africa.

From American possessions 434 students came to college in the United States; 108 from Hawaii; 215 from Porto Rico, and 111 from the Philippine Islands.

THE GEORGE WASHINGTON MEMORIAL

THE jury of award of the George Washington Memorial Association have given first honors to the architectural firm of Tracy and Swartwout, New York.

The members of the committee, Mr. Philip Sawyer, Mr. Charles A. Platt and Mr. Walter Cook, met for the consideration of the award, on May 2, but deferred their decision until May 4 when they came to the conclusion that of the thirteen competing architects, the plans rendered by Messrs. Tracy and Swartwout were the most satisfactory. The selected drawings will now be presented to the National Commission of Fine Arts, and, with their approval, the association will give the architects charge of the construction of the building. The first award is \$1,500, but each competing architect who has submitted plans in accordance with the specifications will receive an honorarium of \$500.

Tracy and Swartwout's drawings depict a fine colonial building with pillared front, and square ground plan. The main feature is the great auditorium seating 6,000 people, which is artistically arranged in the form of an ellipse, with the stage at one end, and a deep balcony encircling the whole. The site of the building is to be in that part of the

Washington Mall known as Armory Square. All the drawings entered in the competition are now on exhibition in the National Museum.

This building, to be known as the George Washington Memorial, and to be administered by the regents of the Smithsonian Institution, was authorized by an Act of Congress passed March 4, 1913. The work of construction must be begun before the fourth of March, 1915, or the authorization by congress for the use of the above site will lapse. It is further provided that the work of construction can not be commenced until the sum of \$1,000,000 is raised by the association, and although Mrs. Henry F. Dimock, president of the association, and chairman of the building committee, has secured a good part of this sum, much still remains to be raised.

SCIENTIFIC NOTES AND NEWS

THE Willard Gibbs medal will be presented by the Chicago section of the American Chemical Society to Dr. Ira Remsen on the evening of May 15.

FORMER students of Professor John Henry Comstock have raised a fund, to be known as the Comstock Memorial Library Fund, which is to be presented to Cornell University for a permanent memorial of Professor Comstock's forty years of distinguished service as instructor and professor of entomology. He is to retire from active teaching as a member of the faculty next June, at the age of sixty-five. The ceremony of presentation will take place on June 13.

THE Academy of Natural Sciences of Philadelphia has elected as correspondents the following: Frank M. Chapman, Edmund Heller, Edgar A. Mearns, Gerrit S. Miller, Charles W. Richmond, Marie Curie, Shibusaburo Kitasato, Charles T. Ramsden and N. Charles Rothschild. The same institution has appointed as delegates to the Nineteenth International Congress of Americanists, Charles D. Walcott and H. Newell Wardle.

At the annual meeting of the New Orleans Academy of Sciences, held at Tulane Univer-

sity on March 17, William Benjamin Gregory, professor of experimental engineering in Tulane University, was elected president of the academy for the ensuing year.

MR. JAMES A. BARR has been appointed director of congresses for the Panama Pacific Exposition.

PROFESSOR ELWOOD MEAD has reconsidered the acceptance of a professorship of rural institutions in the University of California, and will remain chief engineer of the commission of rivers and water supply of the state of Victoria.

THE United States Department of Agriculture has established an office in the bureau of chemistry for the purpose of promoting a closer and more cordial cooperation among the city, state and federal food and drug officials of the country in the enforcement of the food and drug laws. Mr. J. S. Abbott, for nearly seven years dairy and food commissioner of Texas, was appointed to this office and began active service on April 3, 1914.

THE Howard Taylor Ricketts prize for undergraduate research work, awarded on May 3, each year, as a memorial of the death of Howard Taylor Ricketts while engaged in the investigation of typhus fever in Mexico City, is this year awarded to Julian Herman Lewis.

THE Hunterian Society's Medal, offered annually for the best essay by a general practitioner, has been awarded to Dr. Basil T. Parsons-Smith, who took for his subject, "The Intermittent Pulse."

THE Helen Schaeffer Huff memorial research fellowship at Bryn Mawr College has been awarded to Miss Vernetta Lois Gibbons, who will continue her investigation of the potentials of the metals in non-aqueous solutions.

THE trustees of Clemson College have appropriated \$300 for an investigation of the limestone and marl deposits of South Carolina and their value for agricultural purposes. The work will be in charge of Dr.

F. H. H. Calhoun, professor of geology and mineralogy.

DR. L. J. HENDERSON, assistant professor of biological chemistry, has been appointed the professor from Harvard University for the second half of the year 1914-15 under the interchange agreement between Harvard University and the four western colleges—Beloit, Grinnell, Knox and Colorado.

PROFESSOR PERCY E. RAYMOND, of Harvard University, has left for an expedition under a grant from the Shaler Memorial fund to explore regions about the Baltic.

PROFESSOR G. D. HARRIS, of Cornell University, will leave Ithaca early in June in a thirty-foot motor boat to take an inland trip down the Atlantic coast for the purpose of studying the geological formations on the route and to add to the university's collection of geological specimens. He will be accompanied by six or eight graduate students who are specializing in paleontology.

PROFESSOR J. H. LEUBA, of Bryn Mawr College, will be absent next year on sabbatical leave. His work will be taken by Professor E. Wilm, now at Wells College and by Dr. Chester E. Kellogg.

THE University of Pennsylvania Chapters of Phi Beta Kappa and Sigma Xi held their annual joint meeting on May 1, when an address, entitled "The Whole Man," was made by Professor R. M. Wenley, of the University of Michigan.

ON the evening of May 4, Professor C. J. Keyser delivered an address before the Phi Beta Kappa Alumni in New York on "Science and Religion: the Rational and the Superrational."

DR. L. A. BAUER gave the following course of illustrated lectures at the Johns Hopkins University:

May 4, "The General Magnetic Survey of the Earth. I. The Chief Phenomena and Instruments of Investigation used in Ocean and Inland Work."

May 5, "The General Magnetic Survey of the Earth. II. The Results and Bearings of Magnetic Observations."

May 6, "The General Characteristics of the Magnetic Fields of the Earth and of the Sun and Results of Analyses."

May 7, "Résumé and General Theories."

PROFESSOR GUSTAV KILLIAN (Berlin), who will deliver the Semon Lecture at the house of the Royal Society of Medicine, on May 28, has selected for his subject, "Suspension Laryngoscopy and Its Practical Use."

THE Romanes lecture at Oxford University will be delivered on June 10, by Sir Joseph John Thomson, professor of experimental physics at Cambridge. The subject is "The Atomic Theory."

A CONFERENCE under the auspices of the Société des Amis de l'Université de Paris has been held to consider the subject of the fourth centenary of Andreas Vesalius, the great anatomist, who was born in Brussels in 1514. The plan is to erect a monument to his memory on the island of Zante where he died in 1564, next August, under the auspices of the Belgian government.

PROFESSOR NEWTON HORACE WINCHELL, formerly state geologist of Minnesota and professor of mineralogy and geology at the University of Minnesota, died on May 3, aged seventy-five years.

PROFESSOR EDUARD SUESS died on April 26 of pneumonia at the age of eighty-three. Until his eightieth birthday he had been president of the Vienna Academy of Sciences. Professor Suess was not only the dean of modern geologists, but a Liberal politician of the old school, whose parliamentary activity was largely directed against the organized forces of professional obscurantism.

DR. OTTO MAY, honorary professor of agriculture at the Technical School at Munich, has died at the age of eighty-one years.

THE Swiss Society of Neurology has called an International Congress of Neurology, Psychiatry and Psychology to be held at Berne, September 7-12, 1914. An organization committee and various international committees have been appointed.

THE committee having in charge the Samuel D. Gross prize, valued at \$1,500, of the

Philadelphia Academy of Surgery, announces essays in competition for the prize will be received until January 1, 1915. The essays, which must be written by a single author in the English language, should be sent to the "Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians, Philadelphia."

THE board of governors of the General Memorial Hospital, New York City, have voted to enter into an affiliation with Cornell University Medical College for the conduct of the General Memorial Hospital as an institution for the study and treatment of cancer and allied diseases. This affiliation is rendered possible by the gift of a large sum from Dr. James Douglas, which, in addition to the present endowment of the institution will render the hospital largely independent of an income from other sources. The grounds for an affiliation are to be found in the facts: (1) That this institution was originally created for the purpose of cancer treatment and research, but the original funds were insufficient to enable it to enter this field exclusively. (2) The board of governors feel with Dr. Douglas that the study of cancer and the development of the new means of its treatment can be successfully carried out only through the combination of the efforts of laboratory workers specially trained in this field and clinical surgeons. The laboratory staff maintained by the college and the Huntington Fund is available for this work and the medical board of the hospital will be composed of such men, together with the surgeons, as are specially interested in cancer treatment and research. All forms of tumors and malignant diseases as well as cancer are to be included in the scope of the work. The institution duplicates on a large scale other hospitals which have been created in this country and abroad for similar purposes, the best known examples of which are Middlesex Hospital in London and the Samaritan Hospital of the University of Heidelberg.

As a result of recent experiments conducted by a member of the advisory committee on the Langley Aerodynamical Laboratory of

the Smithsonian Institution, a new form of flying-boat hull has been evolved, which appears to have decided advantages over the types now in use. These experiments were made by Naval Constructor H. C. Richardson, U. S. N., chairman of the subcommittee on hydromechanics in relation to aeronautics of the Langley Laboratory, at the model basin of the Washington Navy Yard. Several model hulls were used, some of which represented the different types of naval hulls now in use, one a model of the Curtiss pontoon, and others obtained through changes and improvements in standard forms. They were one ninth full size, except the Curtiss model which was one fourth actual size, and were tested both on the surface of the water and submerged one foot. In his report Naval Constructor Richardson has shown by diagrams and tables the advantages and disadvantages of the various types, as well as the plan, side and end views of five models. Tests were made on the surface of the water for the resistances at "displacements corresponding to speeds," and other tests were made submerged as a means of determining their total head resistance in air, and of ascertaining an approximate coefficient of fineness of form. Further experiments are under way for the determination of the stream line flow about submerged models, as a means of improving the form, and to otherwise perfect the standard type most advantageous for all purposes. Comparisons of the model results and the actual performances of full-sized machines show that a fair analogy exists, confirming the behavior of the models under experiment. Actual experiments with a full sized machine shows the hollow V section very desirable because of the good landing qualities, as landings which would otherwise stress the machine badly have been made without any shock. The report of the experiments forms Publication No. 2253 of the Smithsonian Miscellaneous Collections.

UNIVERSITY AND EDUCATIONAL NEWS

THE gifts to Oberlin College for various purposes during the last months amount to nearly \$190,000, apportioned as follows: For campus

improvement, \$25,000; for a new art building, \$125,000; for a new organ in Finney Memorial Chapel, \$25,000; subscriptions toward the new athletic field, \$14,300. A large number of gifts, mostly anonymous, go to make up the \$125,000 for the new art building.

DR. BEVERLY THOMAS GALLOWAY, assistant secretary of the Department of Agriculture and previously chief of the Bureau of Plant Industry, has been appointed by the trustees of Cornell University to be director of the New York State College of Agriculture. Dr. Galloway takes the place which was vacated by the resignation of Professor L. H. Bailey and which has been filled this year by Professor W. A. Stocking as acting director.

At the University of Missouri, Dr. I. F. Lewis, of the University of Wisconsin, has been appointed professor of botany, and Professor E. J. McCaustland, of the University of Washington, dean of the engineering faculty and director of the engineering experiment station.

WALTER COLLINS O'KANE has been elected professor of zoology and entomology at the Ohio State University. He graduated from the university in the class of 1897 and has been connected with the New Hampshire station for the past four years.

At Cornell University, George A. Works has been elected professor of rural education in the college of agriculture, and David Lumsden assistant professor of floriculture.

DR. GERTRUDE KAM, demonstrator in psychology at Bryn Mawr College, has been made an associate.

DR. DOUGLAS MCINTOSH, associate professor in McGill University, has been appointed associate professor of chemistry and acting head of the department in the newly established University of British Columbia.

DISCUSSION AND CORRESPONDENCE

A NOTE ON THE ACCESSORY CHROMOSOMES OF MAN

In two recent publications in which Montgomery's and my own observations on the accessory chromosomes in man (negro) have

been mentioned; the phraseology of the authors would lead any one who had not read the original papers to the conclusion that there was a decided discrepancy in our results, whereas just the reverse is true. Thus Morgan in his book, "Heredity and Sex," after remarking on my account of the accessories says (p. 245):

Montgomery has also studied the same problem, but his account while confirming the number, is in disagreement in regard to the accessory.

And again Kornhauser, in his "A Comparative Study of the Chromosomes in the Spermatogenesis of *Euchenopa Binotata*, etc.," *Arch. f. Zellforsch.*, Bd. XII., No. 2, speaking of cases in which "the x -element is in the form of two chromosomes in the male" as found by Wilson in *Syromastes*, continues (p. 280):

Guyer ('10) has reported a similar condition in the spermatogenesis of man. This case, however, would seem to need confirmation, for both Gutherz ('12) and Montgomery ('12) have, in the main, been unable to support Guyer's contention.

This last is certainly a surprising statement for any one to make who has read Montgomery's paper, as the following excerpts from his "Human Spermatogenesis, Spermatoctes and Spermiogenesis, A Study in Inheritance," *Jour. Acad. Nat. Sci. Phila.*, Vol. XV., 2d Series, 1912, well attests. Speaking of the chromosomes of the primary spermatoctes he says (p. 8):

I can confirm Guyer's conclusion that there are 12, of which 10 are bivalent gemini, each dividing in both maturation mitoses, and 2 univalent allosomes (accessory chromosomes) which divide only once in the two maturation mitoses. Guyer's view is therefore probably correct that the number in the spermatogonia must be 22 and not 24 as reasoned by Duesberg.

There is a slight discrepancy in Montgomery's and my account of the subsequent behavior of the accessories but even here we agree in the main, for speaking of the ordinary behavior of the accessories Montgomery continues (p. 9):

This is the usual condition and the one discovered by Guyer.

As a matter of fact, the discrepancy lies in the fact that, in addition to this usual behavior, Montgomery records certain atypical cases as follows: five cases in which the members of the double accessory go to opposite poles; ten cases in which the smaller member of the pair divides, one half going with its customary associate to one pole, the other half going alone to the opposite pole; five cases in which the larger member divides; three cases in which both accessories divide. On looking over my material again since the appearance of this and other papers on human spermatogenesis, and also after the examination of some new negro material received in the meantime, I still feel convinced that conditions for the male negro are essentially as I originally described them.

The most decided differences in accounts of human spermatogenesis are those which obtain between the findings of Montgomery and myself on the one hand and von Winiwarter on the other. The latter finds 47 ordinary and one accessory in the male. It must be borne in mind, however, that Montgomery and I worked on the tissues of negroes and von Winiwarter on those of a white man. I am at present engaged in a study of material from two different white men and although not yet ready to make a detailed statement I can say with assurance that the number of chromosomes is considerably in excess of those found in my negro material.

MICHAEL F. GUYER

THE UNIVERSITY OF WISCONSIN,
April 3, 1914

MORAL AND RELIGIOUS TRAINING IN A STATE UNIVERSITY

TO THE EDITOR OF SCIENCE: Chancellor Frank Strong's paper in SCIENCE of November 21, on "Some Educational Problems in Kansas," mentions as one of the great problems confronting education in that state "moral and religious training," saying:

If any were misled years ago into the belief that intellectual training provided sufficient safeguards and moral standards, certainly our experience the last decade must have disillusioned him.

The "if" is a saving word in that state-

ment, to any who might be disposed to disagree with the chancellor, but it still seems a fair question to ask, How otherwise than through the intellect is education of any kind to be conveyed? Also, it would seem to be not altogether out of place to inquire as to exactly what is meant by the terms "moral" and "religious," not to obtrude a discussion of religion in a publication devoted to a quite different purpose, but to make clear the intentions and plans of those, like Dr. Strong, who insist that education is incomplete and dangerous without the application of certain remedies which they have to offer. A few are interested in religion, but all of us in education.

If the meaning of the terms refers to acts of worship, which in their nature are emotional and suggestive rather than instructive, such as prayers, the reading of scriptures and singing of hymns, it is a popular understanding that it is the function of the church to attend to such things, not the high schools, colleges and universities, for in such institutions Jews, Catholics, Greeks, Turks, Chinese, Japanese, Mormons and agnostics often mingle, all with such divergent beliefs touching religion that creedal or sectarian teaching and forms would be wholly out of place. Such students place themselves under instruction to learn the truths of science and history and to study art, literature and languages, not to be proselytized. Like the purchaser of a commodity in trade, they come to buy what they think they need, not what some one else wants to force on them, and if they are forced, in order to get the instruction needed, to take other kinds which are repugnant to their religious convictions, it becomes tyranny.

As to morals, there is no dispute among civilized peoples generally in all parts of the world. Honesty, truthfulness, mercy, forgiveness, unselfishness, restraint of passions, honoring parents—"these and a few others," as Buckle truly said, "have been known for thousands of years, and not one jot or tittle has been added to them by all the sermons, homilies and text-books which moralists and theologians have been able to produce." There could be no objection, of course, to their being taught in the schools if it seemed necessary—

taught directly, not by the subterfuge that they could only follow from religious acts, therefore it is necessary to teach religion—but if made a part of the curriculum I should like to know how large a place our professors would be likely to assign them. Would a three years' course seem too short, or a four year, perhaps, too long to teach a boy that honesty and good habits are right, and the opposite are wrong? Or would such things be assumed to have been taught during childhood in the only proper place—at the mother's knee?

Since Chancellor Strong lays emphasis on the statements, that "after all . . . ours is a Christian civilization," and "Historical Christianity is the basis of our whole life, and we as a nation shall stand or fall with it," he must then mean by the "moral and religious problem confronting education in Kansas as elsewhere" the question of how to bring about the teaching of Christianity by compulsion and at national or state expense, an attempt as out of joint with the times as with the purpose of the founders of the country, that church and state should be forever separate.

HENRY K. WHITE

CATONSVILLE, MARYLAND

SCIENTIFIC BOOKS

THE EASTMAN-ZITTEL PALEONTOLOGY

THE appearance of a second and very much enlarged edition of Dr. Eastman's English version of Zittel's "Paleontology" (Volume 1, Invertebrates) may be accepted not only as an acknowledgment of the usefulness of the work but also as a response to a growing interest in the study of ancient life. It is very probable that the justification for the revision of this expensive and elaborate work comes chiefly from the American demand, and, if this is true, the demand may perhaps be counted among the first fruits of the efforts made by The Paleontological Society to encourage and widen a deeper concern in that field. While this statement has reasonable worth, yet the fact stands out clearly that the Eastman-Zittel "Paleontology" is by far the best, practically the only satisfactory general guide-book and compendium of the science. Even

the first edition was a more useful book than the German original because of its greater detail and closer analyses, though we have been given to believe the innovations in classification introduced by the first collaborators were not altogether acceptable to the lamented and distinguished author, Professor Zittel. But in a science which covers the whole field of life, progress must be rapid; new encyclopedias soon become old as new lands are explored and old ones more closely scrutinized, and old philosophies and classifications give way under the burden of new knowledge. No one person could to-day successfully do what Zittel did—write a book covering the entire field of ancient life. Versatile as he was in many departments of paleontology, competent to expound as he did the structures of sponges and dinosaurs, to-day such diverse efforts would be looked upon with a grave hesitancy by students generally, that would assuredly weaken the voice of authority.

So, in this new book, there is a divided authority, even more pronounced than in the first edition, and the American author, Dr. Eastman, modestly withholds his own name from any acknowledged responsible share in the separate chapters, which leaves us to infer that he did all the work the others did not do (no small amount when one analyzes the allotments) and of course did the real work on the rationale of all the combined chapters.

In giving to SCIENCE a notice of this work, it seems appropriate to restrict it essentially to the new material, either in the form of accretions from later discoveries or of revised classifications, and to present these new features succinctly and with precision the reviewer has asked most of the contributors to briefly state the differences between the old and the new in the chapters with which they have been severally charged.

In the 1899, or first, American edition there were 12 collaborators; in this edition of 14 years later there are 17 coworkers, and but three names of the first list remain on the last: Dr. Dall, Professor Schuchert, Mr. Clarke. The increase in the number speaks of greater refinement of knowledge as well as of wider activity of research in the later years.

The Foraminifera (Joseph A. Cushman) have been given a fuller introductory discussion and the classification is essentially made over. Though without additional illustration, the chapter is essentially new.

The Porifera have been amplified (by the author-editor) with additions on the Hexactinellids, and it is interesting to note the elevation of *Receptaculites* and *Ischadites* from a footnote to a place in the text body.

Regarding the Anthozoa, which have been revised by T. Wayland Vaughan, the editor remarks that the classification adopted, "although perhaps as good as any available, is tentative in character." Among the Tetracoralla there are few changes; in the Hexacoralla Dr. Vaughan has added some important text and illustrations in the general discussion and in the classification are some noteworthy alterations. We notice the family Fungidae and its allies created into a sub-order Fungida, and the omission of the Madreporidae (on the assumption that they do not occur fossil). The extensive array of tabulate corals or favositids is no longer an "appendix to the Hexacoralla" as in the first edition, but more conservatively expressed as an "appendix to the Anthozoa." Into this group *Chaetetes* is admitted, but *Monticulipora*, *Fistulipora* and their allies are put back again among the Bryozoa.

The Graptolitoidea (R. Ruedemann) formerly standing in an "Appendix to the Campanularia," are likewise more broadly considered as a "Class or Subclass of the Hydro-medusae." This chapter has been considerably enlarged in text and illustration and the taxonomy rectified by substituting for the oddly incongruous *subordinal* terms of the early edition Monoprioidae, Diprioidae, etc., the classification wrought out in the author's well-known memoir on these organisms.

The Vermes have been amplified by the introduction of Walcott's recent remarkable discoveries in the Cambrian.

A number of collaborators have revised the Echinodermata: Frank Springer, the Cystoidea, Blastoidea and Paleozoic Crinoidea; Mr. Springer, with A. H. Clark, the Post-paleozoic

Crinoidea; H. L. Clark, the Asteroidea and Holothuroidea, and R. T. Jackson, the Echinoidea. These are distinguished authorities and the amendments they have made must be regarded as well up to the present state of knowledge of these groups. In Mr. Springer's part of the work there is an enlargement of about nineteen pages, and in the classification of the Crinoidea the two authors have rearranged the divisions in better harmony with their geological succession and their recognized structural relation. A striking feature is the inclusion of the stalked pentacrinites and the unstalked comatulids in one family and the union of the genera *Marsupites* and *Uintacrinus* with the comatulids.

A singular and rather confusing thing in this connection is an incongruity in classification which must have escaped the author's eye. The family Pentacrinidae is divided into three sections, one of which, the "comatulids," is divided into three "tribes." The second of these tribes is made to contain many genera grouped into a large number of different families.

Mr. H. L. Clark has given an entirely new classification of the Asterozoa and has amplified the chapter on the Holothurians, including even the Cambrian species discovered by Walcott, though he has elsewhere gone on record as doubting the echinoderm nature of these fossils.

The Echinoidea have been brought up to the stage of Dr. Jackson's exhaustive knowledge of the group, expressed in his recent elaborate treatise on these bodies. New cuts are introduced, some showing structural characters of the group as a whole and others representative Paleozoic echini. In the classification the arrangement is in natural phylogenetic sequence based on a comparative study of development and adult structures.

In the Bryozoa by R. S. Bassler, the Monticuliporoids, which in the last edition were made to appear in the "double and daring act" of both Bryozoa and Anthozoa, are now excluded from the latter, as just observed, because of the recent demonstration of their early budding phases. A revised classification

is presented of the Cyclostomata, with 5 sub-orders, one of them, "Ceramoporoida," being new; a natural division given of the *Trepomatata* and the most recent work on the *Cheilostomata* is included.

In the Brachiopoda (Charles Schuchert) the form of the chapter and the general principles of the classification have been retained, but the latter has not only been elaborated to such completeness as to assemble all outstanding generic divisions of which the later years have added no small number, but have been illuminated by the expression of phylogenetic lines and terminals. This procedure has made necessary the introduction of a good many new divisions of supergeneric value, but it conveys a conception of developmental relationships never before so well expressed.

The chapters on the Pelecypoda, Gastropoda and Pteropoda have undergone no material changes except for the inclusion of new generic terms (W. H. Dall), but in the Cephalopoda by J. Perrin Smith there are notable expansions in both matter and illustration. For some reason the Nautiloidea have been left pretty much as they stood before, though a great deal of work has been done on the group in the last 14 years by Germans and Americans; but the Ammonoidea have been amplified by many new cuts of Carbonic, Permian and Triassic forms. It will surprise many students of this group to find Hyatt's classification, adopted in the first edition, quite entirely cast out in favor of the German taxonomy as expressed by Zittel and of late years amplified by European students and by Dr. Smith, himself a collaborator with Professor Hyatt. The present classification is in a way a trial adjustment of the old and the new.

The Trilobites have been revised by P. E. Raymond, who has enlarged the generic list from 55 genera in 14 families, as in the first edition, to 126 genera in 28 families; a statement which indicates the persistent and growing interest in this group of fossils. The principles of the classification are those followed by Beecher in the first edition. The reviser has incorporated his own interpretation

of many old and rather vaguely defined names, such as some of Corda's and Angelin's, with a generous number of new generic conceptions based upon his own researches.

The Branchiopoda and Ostracoda have been brought up to date by R. S. Bassler with a considerable number of new figures. The Cirripedia and Malacostraca (by William T. Calman; Phyllocarida by J. M. Clarke) are not materially unlike their earlier presentation, while the Arachnida-Merostomata (J. M. Clarke) have been considerably revised with some substitution of old for new illustration, especially of restorations based on the researches recently published by Clarke and Ruedemann. The Arachnida-Embolobranchiata (Alexander Petrunkevitch) are brought into line with recent discoveries with some additional illustration, and the Myriapoda stand very much as they were left in the old edition.

Mr. Anton Handlirsch's chapter on the Insecta is a wholly new and original document of thrice the text matter and twice the illustration of the former edition. The general discussion and the classification are so entirely unlike the original that even a trace of the latter is hard to find. It may well be regarded as the best present expression of information regarding this group.

JOHN M. CLARKE

School Health Administration. By LOUIS W. RAPEER, New York Training School for Teachers. Published by Teachers College, Columbia University, New York City.

Part I, pp. 1-70, gives an outline of national health problems in their relations to the school. Part II, pp. 71-294, summarizes the findings of an intensive study which the author has made of the methods and results of school medical service in twenty-five typical cities in the eastern states. Part III, pp. 295-358, offers a tentative standard plan for the administration of school health work.

The book is the fruit of several years of first-hand investigation of the methods of medical inspection as it is actually carried on. The author goes behind the glowing accounts

found in the reports of superintendents and school doctors, and measures the efficiency of the systems by the application of a few common-sense statistics and the principles of scientific management. He shows in a most convincing way the inefficiency of some of the methods in vogue and offers a plan which ought to be taken as a model until experience shall have given us something better.

The book reveals a broad grasp of the larger significance of educational hygiene, and points clearly to the many dangers of misplaced emphasis in this new but promising field of child welfare. It should be studied especially by school superintendents, school doctors, school nurses and social welfare workers.

The appearance of the book is somewhat marred by a rather unattractive make-up; and the author's style, while vigorous and interesting, is not always as direct and clear as one would like.

LEWIS M. TERMAN

STANFORD UNIVERSITY

INVESTIGATIONS IN THE ATLANTIC OCEAN¹

MEASUREMENTS of the temperature and salinity of the surface water of the Atlantic Ocean have for many years been carried out by route steamers and other vessels traversing these waters. The necessity of systematically conducted investigations, of both hydrographical and biological character, not only at the surface, but also in deep water,¹ is pointed out. Such a systematic investigation of the whole of the Atlantic Ocean must be regarded as one of the most important scientific and practical tasks of the future.

Pettersson and Drechsel were intrusted by the Central Bureau of the International Study of the Sea, with the task of drawing up a memorandum as to the ways and means by which an international reconnaissance of the Atlantic Ocean could be organized in the near future. These gentlemen have conferred with

¹ Abstract of a report by Pettersson and Drechsel. The address of Pettersson is: Professor Otto Pettersson, Holma i Brastad, Sweden.

many of the leading authorities on oceanography in other countries.

The authors concluded, as the result of such conferences, that the matter could not be farthered by the ordinary discussions and resolutions on the part of learned societies. The only way was to seize the first favorable opportunity of commencing the investigations. The first trans-Atlantic hydrographical investigation would probably have to be made from ships in the naval service. Coastal seas could be studied only by real investigation steamers, specially fitted for fishery-biological work.

The following program was drawn up:

I. Investigation of Coastal Seas;

II. Transatlantic Investigation.

These investigations are to be carried out simultaneously, since in this way a more comprehensive view can be obtained of the actual condition of the Atlantic Ocean in summer and winter. After the general survey has been made, special investigations of individual questions can be taken up. To complete such investigations it is important that the countries bordering on the Atlantic Ocean should cooperate. Great Britain and the United States have already cooperated, and France and Canada should also participate. For the investigation of the coastal seas, the following program is suggested.

(a) Quarterly cruises to be made to the *northeastern part of the Atlantic water system*, from Iceland to Spitzbergen, including the North Sea, the Skagerack, the Cattegat and the Baltic.

(b) In reference to the Iceland-Faeroe-Wyville Thomson ridge, the Rockall channel and the mouth of the Channel, it is to be hoped that the former will be investigated by the Scottish, Danish and Norwegian commissions, and the mouth of the Channel by the Irish Fishery Department.

(c) In the sea east and west of Greenland the determination of the conditions with regard to ice is of prime importance. The Danish Meteorological Institute has already done good work in this field.

(d) We do not possess a single hydrographical section through the Labrador current, and

yet this current plays such a prominent part in the water circulation of the Atlantic. Some observations are already being made in connection with the shipping interests.

(e) In reference to the Coastal Sea of North America, discussed under caption (e), it is pointed out that hydrographic observations should be obtained over the area extending 600 miles south 30° east of St. Johns, Newfoundland, returning directly to the Flemish Cape and thence to St. Johns. Also at other points on the "Grand Banks" and neighboring fishing grounds. It is also recommended that quarterly cruises be carried out in the months of February, May, August and November from Cape Lookout to the Bermudas and thence to Florida. Monthly observations should be made on section between southern Florida and Nassau, and between southern Florida and Havana; also in the Atlantic Ocean north of Cape Hatteras.

(f) The Newfoundland Bank and adjacent waters are both scientifically and practically the most interesting area for study, since it is here that we have the conflict between the Gulf Stream and the Labrador current. The bearing of the results obtained on the fishery question would be very direct and very important. The fact that the fishery on the Grand Banks is seasonal would indicate an annual periodicity in the hydrographical conditions. Ways and means are not yet worked out for connecting the study of the Newfoundland Banks with a future, general study of the North Atlantic Ocean.

(g) The Portuguese coast and the Plateau of the Azores can be investigated largely by the Portuguese, who are very much interested in the problem. With the permission of the Portuguese government, two cruisers can make quarterly cruises into these regions.

Transatlantic lines of investigation can be carried out only by direct government aid. To secure this cooperation on the part of the different governments, it is necessary to have a well-arranged program, and to select some "favorable opportunity" for carrying it out. The following program and opportunity are suggested.

The Program

The basin of the Atlantic is divided into two great hollows by a submarine ridge running out from the Cable Plateau. The eastern and western hollows have different hydrographical conditions. The simplest plan would be to draw the transatlantic line of investigation parallel with the degrees of latitude between America and Europe. The northernmost of the three sections should be studied approximately along the fifty-seventh degree of latitude. This would be comparatively simple. The depths of the Cable Plateau are only from 1,000 to 3,000 meters, and this section would cross all of the so-called "Gulf Stream Branches" in the north Atlantic.

The southern sections should be drawn not transversely, but diagonally. One should extend from the mouth of the Channel north of the Plateau of the Azores to the West Indies and the Caribbean Sea. The second should extend from the Straits of Gibraltar south of the Plateau of the Azores to Trinidad.

The study of those two sections would demand a complete equipment for oceanic deep-water soundings, and a staff experienced in such work on board large ships. The best time would be from December to February, since our knowledge of the condition of the sea is especially incomplete in winter.

The Opportunity

It appears opportune that the first Atlantic survey should be made with ships from the Navy, at a time when such vessels are sent out simultaneously from several European countries along the several routes indicated above. Such an opportunity will present itself at the opening of the Panama Canal in January, 1915. European countries will probably be represented by naval vessels, and scientific investigations could be made *en route*, without great expense or serious loss of time.

The Austrian and Italian vessels, coming through the Straits of Gibraltar, could study the southern section. Since a deep-sea sounding requires only about twelve hours, and a sounding of 1,000 meters only a few hours,

the scientific work would not lengthen the voyage more than a week.

The ships sent by the North Sea countries and by Russia, coming through the English channel, could study a section of the Atlantic north of the Plateau of the Azores. The opening of the Panama Canal, which should stand for universal traffic, would likewise form an epoch in the study of the sea, and introduce a future of international cooperation in the scientific activity of nations.

If this opportunity is neglected, it is not likely soon to come again. Experience has taught the difficulties involved in setting in motion an international undertaking of such dimensions; and the opinion is expressed that the time remaining would just about suffice for the diplomatic, scientific and technical preparations.

In preparing the above synopsis the words of the authors are frequently used.

H. C. JONES

SPECIAL ARTICLES

THE POOR NITRIFYING POWER OF SOILS A POSSIBLE CAUSE OF "DIE-BACK" (EXANTHEMA) IN LEMONS

THE disease known as "die-back" in citrus trees has, for many years, worried the citrus growers of Florida and California in this country and has thus far baffled the efforts of the agricultural scientist to discover its cause. The writer has recently made some observations and experiments on several citrus soils bearing trees affected with "die-back," which lead him to believe that a poor nitrifying power on the part of the soil, with the ammonifying power remaining normal, may be the cause of the peculiar manifestations which are characteristic of the disease and which, for the purposes of this preliminary report, need not be described. The theory upon which I am working at the present time, looking toward the solution of this problem, is that in the absence of normal nitrification and in the presence of sufficient ammonification, the tree does not obtain a sufficient quantity of nitrate for its development and is sooner or later forced

to assimilate ammonia compounds as produced by ammonifying organisms in the soil; or in the presence of a sufficient amount of bases in the soil even the ammonia may be set free, thus causing the plant to starve for want of nitrogen. While it is true that some plants can use ammonia compounds just as well as nitrates as a source of nitrogen and further, that some of them even prefer the ammonia compounds, as Kelley has shown is the case with rice, it is very possible that we have in the citrus tree, a plant which is deleteriously affected by ammonia compounds when it is forced to absorb them. As above explained, however, when a soil's power to fix and hold ammonia is very feeble, owing to the presence of bases in excess, a poor nitrifying power and a strong ammonifying power may mean nitrogen starvation for plants on that soil. The writer has examined and tested the nitrifying power of four citrus soils in various parts of California, on which trees were suffering from "die-back," and has found in every case a very slight nitrifying power or none at all. The tests were made by adding to soils, kept at optimum moisture conditions at a temperature of 26 to 28 degrees C. for approximately a month, both dried blood and sulfate of ammonia, but only slight or no increases of nitrates over the amount in sterile checks or dry soil were obtained. The dried blood was used also in varying quantities from 1 per cent. up to 5 per cent. of the dry weight of the soil, but the same results were obtained in all cases. In some of these soils, particularly, the ammonification of the blood proceeded so rapidly as to give an intense odor of ammonia when the Petri dish cover was raised from the tumbler in which the soil cultures were kept.

This theory of the writer's which inclines to account for the "die-back" by the fact that too much ammonia is assimilated by the tree under compulsion in the absence of nitrates, or, under certain circumstances, because ammonia is set free and therefore there is scarcely any nitrogen for the tree to assimilate, would also seem to be in part confirmed by the observations made by Florida investigators on the disease in question, in which it was noted that in all cases the application of organic

manures to citrus groves invariably made conditions worse or increased the amount of "die-back." In accordance with the idea above expressed, and in the absence of nitrification, this would be for the reason that either the added organic matter would be responsible for the formation of so much ammonia, which (through its enforced absorption) would poison the plants or because, under some soil conditions, most of the ammonia would be set free and pass off into the atmosphere in a gaseous form, thus inducing nitrogen hunger.

I feel justified in transmitting this brief preliminary note on the subject in question, before the theory has been fully tested out, by the fact that the disease known as "die-back" has been studied in many different ways without giving encouraging results, and, because, further, this new method of attack related to the chemical and bacteriological conditions of the soil, as affecting plant nutrition and as applied to a problem of this kind, deserves to be called to the attention of other investigators working along this or similar lines. I am vigorously proceeding to test out the theory above given by simultaneous greenhouse and field experiments with citrus trees which are now under way, in which, on the basis of what I have said above, I am not only trying to overcome the disease by variously treating soils in the field, so as to provide a plentiful supply of nitrates and reduce ammonification, but I am also making an effort to produce the disease experimentally in the greenhouse with seedling citrus trees on soils deficient in nitrates by the addition to the latter of various ammonia compounds, and to overcome it by means of adding stimulants for the nitrifying bacteria. The writer feels confident that a definite relationship may be shown between the abnormal soil conditions mentioned and the "die-back" of the lemon and perhaps as well of other citrus trees, when the experiments have progressed far enough. The theory above enunciated is not only in accord with the Florida observations, but also with all other observations with which I have become acquainted in respect to the disease known as "die-back." Moreover, it allows for the production of bad soil conditions which

will result in a poor nitrifying power through a large variety of causes. Such are, for example, the poor physical conditions of soils, unfavorable drainage conditions, the presence of a vigorous denitrifying flora of one kind or another, and many other chemical, physical and bacteriological conditions, not to mention conditions respecting the origin of the soil which would seriously affect the nitrifying power thereof.

These lines for the most part were written about a year and a half ago when I first formulated the theory, and may need slight revision and some additions in the light of many new facts with which we are now acquainted, but, in the main, the theory seems to be better supported in fact at the present time than it was two years ago. Moreover, it seems very probable now, from a large series of tests which we have been making, that not only "die-back," the true *exanthema*, is to be accounted for by the theory under discussion, but also that the equally disastrous, and much more widely spread disease known as "mottled leaf" of citrus trees is capable of being explained in a similar way, if I may regard a large series of tests on various soils in this state as a reliable criterion. Quite unlike the "die-back," the "mottled leaf" condition in citrus trees is to be found in all citrus districts of California, and is at the present time regarded as one of the most menacing factors in the production of citrus fruit for profit here.

The "die-back" and "mottled leaf" conditions of some districts in this state are becoming so bad as to make it imperative to solve these questions as quickly as possible from the practical standpoint alone. One orchard on which, in particular, the writer is working, has a very large proportion of its trees badly affected by the first-named disease, and most trees in the orchard show some manifestation of the disease. The trees are about four years old and had for a time grown vigorously, and then suddenly began to give symptoms of one of the worst and most widespread cases of "die-back" of which we have knowledge in the state. It is hoped that our experiments may serve eventually to remedy such conditions.

A description of detailed experiments will soon appear.

UNIVERSITY OF CALIFORNIA

THE WATER CONTENT OF THE EMBRYONIC NERVOUS SYSTEM

GROWTH and morphological differentiation go hand in hand in the developing organism, but obviously growth alone can not lead to an increase in the complexity of form without itself being differential. The various tissues and organs of the embryo, however, do grow at different rates, and since, in general, rate and extent of growth are measurable in terms of the rate and extent of water absorption, it follows that differential growth must depend on the ability of the embryonic tissues to absorb and hold, relative to their dry substance, different amounts of water. That this must be true at some period in development follows from the comparative dry substance determinations familiar to every one, but how early in the ontogeny differential absorption occurs has not been known, although its importance as a factor in morphological differentiation has been hinted at often enough.

My investigation of this question was begun on the embryos of *Rana pipiens* in the spring of 1913. The methods employed were tedious but simple. In one series of experiments eggs were allowed to develop normally until a time when the body of the embryo could be cut from the yolk by means of a very thin knife. The division was accomplished easily with a minimal loss of material. Unfortunately the various tissues in the separated portions can not be isolated, but even if this were possible, an unavoidable error due to the presence of considerable quantities of yolk within the cells of the nervous system would remain. However, at the stage of development under consideration, it is safe to assume that the operation results in the separation of two masses, one of which is predominantly yolk, the other, predominantly nervous tissue.

The separated masses were carefully weighed in closed vessels after removal of the super-

ficially adhering water. Following the determination of the fresh weight, the material was reduced to absolute dryness in vacuo over P_2O_5 . The results of two series of weighings given in Table I. are:

TABLE I
(*Rana pipiens*)

	Fresh Weight, Gr.	Dry Weight, Gr.	Dry Substance, %	Water, %
24 yolk sacs.....	.0440	.0204	46.4	53.6
31 yolk sacs.....	.0585	.0264	45.2	54.8
Average.....			45.8	54.2
24 nervous systems.....	.0464	.0098	19.1	80.9
31 nervous systems.....	.0714	.0149	20.8	79.2
Average.....			19.9	80.1

Control observations on embryos of *Amblystoma punctatum* were then made, but, owing to technical difficulties, it proved easier to compare the water content of the nervous system with that of the entire embryo rather than with that of the tissues constituting the yolk sac. The results of these preliminary determinations were as follows:

TABLE II
(*Amblystoma larvæ*)

	Fresh Weight, Gr.	Dry Weight, Gr.	Dry Substance, %	Water, %
16 larvæ.....	.0955	.0399	41.8	58.2
15 larvæ.....	.0992	.0406	40.9	59.1
Average.....			41.4	58.6

These figures may serve as a basis for comparison with the water content of the nervous system. As Table III. shows, the values for the latter are identical with those for the frog embryo, and belong to an order of magnitude quite different from the values for the larval body taken as a whole.

Comparing these values with the corresponding ones found for the frog embryos, we may say, within the limits of error, that the larval nervous system of these amphibians is a tissue which contains 80 per cent. of water and 20 per cent. of dry substance.

TABLE III
(*Amblystoma* larvæ)

	Fresh Weight, Gr.	Dry Weight, Gr.	Dry Substance, %	Water, %
52 nervous systems.....	.1756	.0400	22.8	77.2
15 nervous systems.....	.0524	.0106	20.2	79.8
69 nervous systems.....	.2039	.0363	17.8	82.2
Average.....			20.3	79.7

If we wish to institute a comparison between the water content of the embryonic nervous system and the corresponding adult structure, it is more correct to use the water content of the cord, for this is less differentiated than the brain and consequently more nearly resembles the larval condition. Donaldson¹ has given the water content of 12 cords of *Rana pipiens*. The average is 80.5—identical with my value of 80.1 for the larval system.

Comparisons were also made between the water content of the anterior and posterior ends of the embryonic nervous system. For this purpose I divided 125 isolated larval nervous systems of *Amblystoma* in two, as accurately as possible, in the medullary region. Dry substance determinations of the separated portions were then made with the following results:

TABLE IV
(*Amblystoma*)

	Fresh Weight, Gr.	Dry Weight, Gr.	Dry Substance, %	Water, %
125 larval brains.....	.1812	.0342	17.2	82.8
125 larval cords.....	.2102	.0443	21.0	79.0

These results are in the same sense as those reported by Donaldson,² as the water content of the brain of an adult *Rana pipiens* is 84.9 per cent., or 4.4 per cent. higher than that of the cord. My results on *Amblystoma* indicate that the larval brain contains more water than the attached cord.

¹ Donaldson, Henry H., "Further Observations on the Nervous System of the American Leopard Frog, *Rana pipiens*, etc.," *Journal of Comparative Neurology and Psychology*, Vol. 20, p. 2.

² *Loc. cit.*, p. 2.

We may conclude therefore that the nervous system as a whole has a specific capacity for holding water and that this specificity exists from the beginning. This can be the outcome of nothing other than a physical-chemical specificity, and we must suspect that the nervous system differentiates as a morphological entity, because its chemical differentiation endows it with a specific capacity for holding water. Moreover, two regions as sharply distinct, morphologically and physiologically, as brain and cord have each their own specific capacities, and these although not differing as widely, perhaps, as in the adult, are nevertheless at variance in the embryo in the same sense. The thought lies near at hand, therefore, that the gross structural differences between brain and cord brought about during the course of development are definitely related to the fact that their respective rudiments maintain each its own specific relation between the amount of dry substance and the amount of water.

OTTO GLASER

UNIVERSITY OF MICHIGAN,

April 3, 1914

CONFERENCE ON INDIVIDUAL PSYCHOLOGY

FORMER pupils of the department of psychology of Columbia University held a reunion and conference at the university, on April 6-8, and on the latter date gave a dinner to Professor James McKeen Cattell in celebration of the twenty-fifth anniversary of his first appointment as professor of psychology. This first appointment was at the University of Pennsylvania, and Professor Witmer, of that institution, one of Professor Cattell's earliest students, participated in the dinner. On this occasion a volume entitled "The Psychological Researches of James McKeen Cattell: A Review by Some of His Pupils," written by Messrs. Thorndike, Wells, Henmon, Dearborn, Hollingworth and Woodworth, was presented to Professor Cattell.

The program of the Conference follows:

Monday, April 6, at 3 P.M.

Chairman, PROFESSOR CATTELL

"Individual Differences in Sense Discrimination": V. A. C. HENMON (Ph.D., 1905), professor

of educational psychology, University of Wisconsin.

"Individual Differences in Reaction Time": SVEN FROEBERG (Ph.D., 1908), professor of philosophy and psychology, Upsala College.

"Individual Differences in the Judgment of Unitary Colors": A. T. POFFENBERGER, JR. (Ph.D., 1912), instructor in psychology, Columbia University.

"Possible Effects of Practise on Individual Differences": MARY T. WHITLEY (Ph.D., 1911), assistant professor of educational psychology, Teachers College, Columbia University.

"Successive Measurements of Individual Ability": WARNER BROWN (Ph.D., 1908), associate professor of psychology, University of California.

Monday, April 6, at 8 P.M.

Chairman, EDWARD L. THORNDIKE (Ph.D., 1898), professor of educational psychology, Teachers College, Columbia University.

"Individual Differences in School Children": ELMER E. JONES (Ph.D., 1908), professor of the history and philosophy of education, Indiana University.

"The Reliability of Certain Psychological Tests for Determining the Mental Efficiency of Children": FRANK G. BRUNER (Ph.D., 1908), assistant director, department of child study, Chicago Public Schools.

"Feeble-minded Children as a Species": NAOMI NORSWORTHY (Ph.D., 1904), associate professor of educational psychology, Teachers College, Columbia University.

"Correlations between Entrance Examination Grades and College Records": ADAM LEROY JONES (Ph.D., 1898), chairman of the committee on undergraduate admissions and associate professor of philosophy, Columbia University.

Tuesday, April 7, at 3 P.M.

Chairman, R. S. WOODWORTH (Ph.D., 1899), professor of psychology, Columbia University.

"Cranial Measurements in Relation to Intelligence": W. C. RUEDIGER (Ph.D., 1907), professor of educational psychology, George Washington University.

"The Intelligence of Negroes": MARION J. MAYO (Ph.D., 1913), head of department of mathematics, Eastern District High School, Brooklyn.

"The Psychological Point of View in Ethnology": A. A. GOLDENWEISER (Ph.D., 1910), instructor in anthropology, Columbia University.

"A Note on Primitive Association of Ideas": ROBERT H. LOWIE (Ph.D., 1908), associate curator of anthropology, American Museum of Natural History.

"The Measurement of Attention": HERBERT WOODROW (Ph.D., 1909), associate professor of psychology, University of Minnesota.

"The Relation of Recall to Recognition Memory": GARRY C. MYERS (Ph.D., 1913), instructor in psychology, Brooklyn Training School for Teachers.

"Visual Rhythms": KATE GORDON (Ph.D., Chicago, 1903), professor of educational psychology, Bryn Mawr College.

Tuesday, April 7, at 8 P.M.

"Some Applications of Psychological Tests to the Determination of Industrial and Professional Fitness": B. B. BREESE (Ph.D., 1899), professor of psychology, University of Cincinnati.

"Individual Psychology and the Problem of Vocational Guidance": F. G. BONSER (Ph.D., 1910), associate professor and director of industrial arts, Teachers College, Columbia University.

"The Reliability of Judgments of Mental Ability, with Applications to the Selection of Persons for Positions": B. R. SIMPSON (Ph.D., 1912), instructor in psychology, Brooklyn Training School for Teachers.

"Relation of Earning Power to School Performance": D. EDGAR RICE (Ph.D., 1912), secretary, Pratt Institute.

"An Empirical Study in Valuation": E. K. STRONG, JR. (Ph.D., 1911), fellow in advertising, Columbia University, appointed professor of psychology, George Peabody College for Teachers.

"An Empirical Study in Valuation": E. N. HENDERSON (Ph.D., 1903), professor of education, Adelphi College.

Wednesday, April 8, at 3 P.M.

"Traits of the Psychoses from the Standpoint of Individual Differences": F. LYMAN WELLS (Ph.D., 1906), psychologist at McLean Hospital; lecturer on pathological Psychology, Harvard University.

"Indications of a Connection between Accidents, Divorce, Alcoholism, Illegitimate Birth and Mental Defect": SIEGFRIED BLOCK, M.D. (M.A., 1910), Medical Examiner, Children's Court, Brooklyn.

"Further Studies of the Only or Favorite Child in Adult Life": A. A. BRILL (M.D., 1903), chief of clinic, department of psychiatry, Columbia University.

"Individual Differences in Dreams": LYDIARD H. HORTON (M.A., 1911), interne in psychopathology, Boston State Hospital.

"Practical Aspects of Individual Differences in Practicability": H. L. HOLLINGWORTH (Ph.D., 1909), assistant professor of psychology, Barnard College, Columbia University.

"The Activity Attitude and Meumann's Individual Types of Will": MARGARET FLOY WASHBURN, Ph.D., professor of psychology, Vassar College.

Others whose names were on the printed program, but who were unfortunately unable to appear, were Professor Walter F. Dearborn, of Harvard University; Professor S. I. Franz, of George Washington University, and scientific director at the Government Hospital for the Insane, and Dr. Edwin Grant Dexter, director of the Canal Zone Museum at Panama.

R. S. WOODWORTH

DIONIC WATER TESTER

Substitutes an extremely simple measurement of electrical conductivity for the chemical reactions hitherto employed. Entire test takes less than a minute to perform. By the use of this apparatus, any unskilled person can detect and measure traces of impurities so small as to escape chemical analysis. It has been found for measuring slight traces of impurities in distilled water, sewage pollution in rivers, the hardness of water, etc. When it is desired to know how much of a known substance is present in the water, the Dionic Tester gives the answer with a rapidity and simplicity unapproached by any other method.

THE Moscow Natural Eye Model

Pat. Feb. 3, 1914.

A New and Valuable Aid in Teaching Anatomy and Physiology of the Eye

These models consist of a real, natural eye which has been hardened and fixed; then sectioned in half and mounted in a glass cell so as to show all the internal parts of the eye ball. These structures are all held in their normal positions, and may be easily identified by means of the diagrammatic cut, keyed to model, which accompanies each one.

"The Moscow Natural Eye Models are excellent preparations. We find them to be a great help in laboratory work, in Zoology, Physiology, Anatomy, etc., etc." Dr. J. E. Wodsedalek, Professor of Zoology, University of Idaho.

Mounted in ebonized box with hinged cover, which protects the glass cell from injury. Absolutely permanent, and fully guaranteed.

Fuel Solid, Liquid, and Gaseous

By J. S. S. BRAME, F.C.S., Instructor in Chemistry, Royal Naval College, Greenwich, Lecturer on Fuel, Sir John Cass Technical Institute, Aldgate. With 73 Figures and 55 Tables.

Svo. Pp. xvi+372. \$3.50 net. (Weight, 34 oz.)

Endeavor has been made in this book to place before the technical man, who is not a fuel specialist, but who requires a good general knowledge of the subject, as full information on all fuels of importance as space permits: at the same time the scientific principles underlying gas producer practice, combustion, etc., have not been neglected. The application of fuels to other purposes has not been overlooked, but primarily fuels are considered in their relation to power. As far as possible the diagrams have been chosen to illustrate principles and typical forms of plant and apparatus.

Geological and Topographical Maps

Their Interpretation and Use: A Handbook for the Geologist and Civil Engineer

By ARTHUR P. DWERRYHOUSE, D.Sc., F.G.S., Lecturer in Geology in the Queen's University of Belfast. With 90 Figures and 2 Tables. Svo. Pp. viii+133. \$1.25 net. (Weight, 18 oz.)

A text-book dealing with the practical problems which are involved in the interpretation of maps, descriptions and instructions that will enable the civil engineer and the student of geology to draw sections of the country depicted upon maps, and to ascertain the depths and thickness of the various strata of which it is built up, and their relations to the surface of the ground and to each other.

A brief summary of the main structural features of rocks is included, for the benefit of those unable to obtain a systematic course of instruction in geology.

BAUSCH & LOMB Combined Drawing and Photomicrographic Apparatus

Apparatus Arranged for Drawing with
instrument Horizontal

A LABORATORY equipment of exceptionally wide scope, providing primarily for the enlarged reproduction of microscopical objects in several different ways. Its many possibilities include:

1. Drawing with apparatus in either horizontal or vertical position.
2. Photomicrography with camera either horizontal or vertical.
3. Microscopical projection.
4. Gross photography of large sections or of solid objects.
5. Lantern slide projection.

The outfit also provides convenient illumination for general microscopical research work, such as dark ground illumination, etc. Convenient adjustments permit quick interchange in all cases.

THE subject of the address which I am to have the honor of presenting before you this evening was suggested to me on hearing recently a statement to the effect that it is the duty of society to pay for the services of the botanist. It seems to me that there is something to be said on the other side of this question, and, although my predecessors on similar occasions have almost invariably favored you with learned scientific discussions, I shall depart from that ancient and time-honored custom and invite your attention to a consideration of some of the social obligations of the botanist.

A distinguished and honored member of this society has defined botany as that science "that occupies itself with the contemplation of plant as related to plant, and with the whole vegetable kingdom as viewed philosophically—not economically or commercially in its relation to the mineral, on the one hand, and to the animal on the other." From this definition it naturally follows that a true botanist is one who is engaged in research upon plants as such without regard to the relationship they may bear to the welfare and activities of mankind. The history of botany clearly shows that botanists have ever been largely devoted to their science for its own sake, for the pleasure which they might derive from a knowledge of plants. The speculations in which they were absorbed concerned questions of truth and not those of economic values. But throughout the history of the race, the economic aspect of

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

¹Address of the retiring president before the Botanical Society of Washington, March 3, 1914.

plants has been of fundamental importance to man, since upon them he has ever looked not only as the chief source of the three great necessities, food, clothing and shelter, but also as the means whereby he might cure his bodily ills or otherwise contribute to his comfort and satisfaction. As society became more and more highly organized, there emerged groups of men whose interest centered upon some particular phase of plant utilization which through long-continued study and observation became sufficiently developed to be recognized as an art. The lineal descendants of these groups we recognize to-day in our practical gardeners, horticulturists, foresters, agriculturists and pharmacists. The radical difference in the point of view, between those devoted to botany as a science and those engaged in the practise of its art, ultimately led to the development of a species of class consciousness more than traces of which unfortunately are still in existence. The botanist dazzled by continued contemplation of the aphorism "science for science's sake" became unable to see any science in the practise of the art of botany, and relegated its followers to the limbo of tradesmen along with the smiths, the carpenters and the shoemakers. On the other hand, the groups interested in the practical or industrial aspects of plants came to look upon the professional botanist as a harmless individual who succeeded very well in entertaining himself, but whose activities were of little if any significance to those whose primary interest in plants was utilitarian.

This class conscious attitude on the part of those who approached the study of plant problems from such widely different points of view led to results of the most profound significance. Botanists in their zeal to preserve their ideal unsullied, and in their fear lest utility should obscure its luster

devoted themselves almost exclusively to a dendritic development of their science, the industrial branches of which remained rudimentary if they were not wanting entirely. Until within recent years, the concept of the function and content of the instruction in botany given in our colleges and universities was derived purely from a consideration of the philosophical aspect of botany. In some institutions at least the sentiment prevailed that the courses in botany planned primarily to develop the scientific attitude of mind and habits of thought, had as their chief and legitimate goal the training of students to become teachers of botany. But notwithstanding the increase in the number of institutions of learning, and the consequent multiplication of opportunities for the teacher of this subject to secure a position in which he could maintain himself in a modest way, the possibility of earning a livelihood as a teacher became more and more remote, as an increasingly large number of students graduated and became available as teachers of botany. The inevitable consequence was that many men were turned aside from the pursuit of botany as a profession and entered upon other vocations, which promised to be more remunerative.

But at length there dawned a new conception of botany, one destined not only to modify profoundly the opinion of the public at large with respect to this science, and to revolutionize in many respects the attitude of its exponents in the lecture room and laboratory, but also to pave the way for bringing into sympathetic understanding the workers in widely separated fields of botanical activity. The causes underlying the development of this new conception, which in brief is the recognition of the fact that botany may be utilitarian and still be botany—may be reduced to two, one of which is economic, and the other social.

The economic cause is to be found in the tremendous expansion of technological enterprises which is characteristic of this industrial age. Developments in the field of agriculture have created a demand for men who have been trained to deal with plants in their practical aspects. Trade and industry have recognized the value of the aid which is to be had from science, and have fostered schools for education along technical lines. In response to the demands of technology, many scientific workers have directed their attentions to practical problems, and one result of their combined labors is seen in the change of point of view with respect to botany, and the wider recognition of its utilitarian phases.

The existence of what I have called the social cause, as well as the part which it has played in reshaping the conception of the proper sphere of botany, may not be readily granted, but its absolute denial would certainly impugn the motives of many of the most devoted and conscientious workers in this field of science. This cause had its origin in the fuller realization and clearer perception of the social obligations of botanists. By social obligation is not meant the friendly association with fellow-workers, or the attendance on dinners, and dances, or afternoon receptions, but the obligation of the botanist, as a botanist, to society as a whole.

So long as botanists were economically independent, or so long as they found it necessary to rely upon some regular profession for a livelihood and devoted only their leisure hours to the acquiring of knowledge regarding plants, they could justly be held accountable only to themselves for the nature and direction of their studies. But as economic development advanced, and division of labor became more pronounced, many people of leisure and

culture found it necessary to devote their attention almost exclusively to their business affairs, and the number of professional botanists of independent means became absurdly small in comparison with the number of those who received compensation for their services. For society, recognizing that education along broad and liberal lines was of paramount importance in the up-building and perpetuation of our social institutions, has endowed professorial chairs, built commodious structures and supplied the means for securing the extensive equipment necessary for the prosecution of research and the giving of instruction as well as for the support of the teachers and investigators. Thus the economic status of the botanist changed and brought about a corresponding modification in his social obligations, which in turn led to a broader appreciation of the significance of service. Whoever accepts support from another, be that other an individual or society as a whole, does so either upon the basis of charity or upon the condition of giving an equitable return in service rendered. There is no one worthy of the name of botanist who does not scorn the former, and perhaps none who is not satisfied that he is meeting the latter condition. But who is to be the arbiter as to the equitableness or character of the service rendered? The botanist? Yes, if he is deeply imbued with a right sense of his obligation to society, but if not, if he is one of those who mistake knowledge for an end itself instead of a means to the broadening and energizing of human existence, society will sooner or later relegate him to the place now occupied by the astrologer and the alchemist. Society then has the right to demand, and it is the obligation of the botanist to render service that has a distinct and plainly discernible economic or social value. This does not mean that botanists should con-

sider plants only from the industrial point of view, but it does require the abandonment of the dogmatic attitude which has so long been hostile to any union of philosophical interest and industrial needs. It means the obliteration of the class line between the nobility of wild growing plants and the bourgeoisie of cultivated species; it means the recognition and acknowledgment by teachers and investigators that very practical and commonplace subjects, such, for example, as the germination of ordinary garden seeds, often present as profound theoretical problems as those which are far removed from the field of possible utility; it means the recognition of the principle aptly stated by a recent writer in another connection that "It is the interaction of various types of human thought and investigation, and not mutual isolation or contempt, which helps us all, while he does best who works with the profoundest theoretical problems and the most intensely practical interests at once pressing upon him, with the widest and most philosophical breadth of view, and the most faithful special labor, at once demanding attention."²

The socialization of industry and the specialization of almost every line of human endeavor has necessitated fundamental changes in the spirit and methods of education. No longer is the hope held out that more than a fraction of the students that fill our schools and colleges can win a competence in the learned professions, and large numbers must be encouraged to look for their life work in some line of activity closely associated with industry. To such of these as may choose an occupation in which practical knowledge concerning plants will be of benefit, the social obligation of the botanist is clear. He should encourage rather than discountenance in-

vestigations of a very practical nature, relying upon his own endowment with the true scientific spirit to so shape and direct the work of his students that it may lead to the development of the desired scientific attitude of mind toward the fundamental principles of plant life. To be sure it will be objected that in such a course lies the danger that education will become a merchandise and science be degraded into a mere trade. It is feared that the time spent in learning anything which can not be turned into money will come to be considered as lost and that no longer will there be any interest in the search for truth that does not bear the earmark of utility. It seems to me, if there is any danger to the future of botanical science, that it lies in an entirely different direction, that is, in the failure to recognize the great possibilities for the development and stimulation of widespread interest in the more theoretical aspects of this subject, growing out of its relation to the material affairs of men in general, for just as our social workers have learned that religion offers poor comfort to the man whose stomach is empty, and whose body is imperfectly clothed, so botanists must come to see that their philosophy will mean little or nothing to the great mass of society unless it finds some expression along lines of human interest and necessity.

It is a social obligation of the botanist to insist that the standards by which he is to be judged shall be those of personal value rather than the standards of wealth. Measured by the latter, his position in the economic scale may be regarded as comparable with that of the wage-earner or his fellow worker in the trades, whose usefulness to society is largely measured by his ability to adapt himself to the material and often mechanical requirements under which he must perform his task. The usefulness

² Royce, J., *SCIENCE*, N. S., Vol. 38, 1913, p. 584.

of the botanist, however, can not be so measured, for the service which he renders to society is of an order entirely different from that of the craftsman. His work is to explore the boundaries of knowledge in his search for additional truth, to break the bonds of tradition and opinion when they fetter progress in the solution of scientific problems, and through creative thought to advance the science of botany and its useful applications. The value of his service is not necessarily conditioned by his salary, his degrees, his hours of work or the number of his printed pages, but it does depend, in part at least, upon his open-mindedness to truth, upon his ability to direct his efforts along productive lines, upon the validity of the conclusions based upon his researches, upon the contribution which his discoveries make to social welfare, and upon his power to inspire and right to retain public confidence in the value of botanical investigations. Through his deep sense of community of interest and the recognition that his studies may be of service to all mankind, he thus places himself beyond the pale of economic class distinctions, and is entitled to be judged solely by his personal value.

Nevertheless, botanists themselves have a tendency to judge each other by standards which fall far short of those of personal value. Too often is the sign accepted at par value when the thing signified is only debased currency. An array of scholastic degrees and a long list of titles of published articles may gain for the fortunate possessor a recognition wholly disproportionate to the service he is rendering either to science or to society. The much-deplored tendency to "rush into print" on slight provocation or on no provocation at all, and the frequent occurrence of the legend "Read by title" in the proceedings of our societies and associations, is at least

presumptive evidence that judicious advertising is not without its reward to the individual irrespective of any other results that may follow. The objection which may here be made, that men who are widely separated can come to know each other's work only through their respective publications, answers itself, for the argument is entirely against setting up as standards of measurement, degrees, instead of the personal value to society of the man bearing the degree, and against regarding titles of publications rather than the merits of the publications themselves.

When scientific men overestimate the importance of its symbols to the neglect of achievement itself they give hostages into the hands of those who seem to think that scientific activity can be measured according to some fixed standard, and its value expressed in numerical terms. They also limit and restrict their usefulness to society when too much account is taken of those personal distinctions which are often made between workers in different lines of scientific activity and sometimes between those in lines which are closely related. It is necessary to emphasize the standard of personal value and to insist that a clear distinction be made between the nature of the task of the scientist and that of the industrial worker if the former is to remain free from checks and hindrances which are incompatible with true scientific progress, and if he is to be awarded recognition on the basis of his real contribution to the progress of civilization.

It is a social obligation of the botanist to be a man of affairs. The outlook for the future is that the bond between scientific investigation in botany and economic work will become closer and stronger, and that botany, already occupying an important place in the applied sciences and in human affairs, will gain even wider recog-

nition as one of the permanent forces underlying social progress and activity. Time will bring greater and more insistent demands for the extension of inquiry into every field where the application of the fundamental laws and principles developed through the scientific study of botany promises to minister to the needs of humanity. The organization and direction of the botanical work of the immediate future, in a manner that will preserve the proper balance and correlation between scientific research of the broadest and most fundamental character, and investigations undertaken largely or entirely for economic ends can be successfully accomplished by men who are not only broadly trained botanists, but who are men of affairs, as well.

Scientific progress is not accomplished by the mere accumulation of knowledge, but follows only when knowledge is communicated and brought within the grasp of all who are able to utilize it in any phase of human endeavor. The rapidity with which new knowledge makes its way and the extent to which it finds ready acceptance and assimilation depends upon the terms in which it is formulated, upon the clearness and thoroughness with which its relationship to other forms of knowledge is presented, and upon the number and variety of its possible applications which may be pointed out. Manifestly, he who will succeed best not only in securing the fullest appreciation and utilization of the results of his work, but also in obtaining merited personal recognition for his services, is he who retains a broad and liberal point of view with respect to the related branches of his science, and who is able to put himself into sympathetic relations with men who differ widely in interest and activity.

The scientific worker who would remain in the most active lines of modern prog-

ress, and who appreciates the disappointments and discouragements that often fall to the lot of one who has failed to keep in sympathetic relations with the spirit and purpose of the age in which he lives, will find it desirable not only to acquaint himself with developments in lines of scientific investigation widely separated from his own, but also to extend the scope of his mental horizon until he can obtain a clear view of the readjustments and changes which are constantly taking place in the domains of industry and education and in the fields of political and social affairs. The idea here expressed may be regarded as wholly fatuous and incapable of realization, but the fact remains that specialization alone will lead to a dendritic or tree-like development of science, which instead of conducing to general progress, will ultimately operate as a hindrance to it. Indeed, the development of a science is in many respects analogous to the evolution of a species of organisms, for just as the latter make evolutionary progress (I here quote a well-known writer on organic evolution) only through being "connected with each other by an intricate network of descent in the weaving of which the diversities of the members of a species have a definite physiological value," so will a science approximate the maximum limit to its capacity for progress only through the continuous interaction of the ideas and the integration of the principles developed in its various phases and aspects.

It is a social obligation of the botanist to study processes, to penetrate more deeply into the mighty forces of organic nature to the end that they may be brought more completely under the control and direction of man. The satisfaction of human wants is in a large degree dependent upon processes which have been slowly built up by plants through countless ages of

gradual development, and since the laws governing them are not sufficiently well understood, these processes have played a small part in the advancement of industry. We have no choice, for the most part, but to accept such products as the plant may yield, instead of being able either to fully control its activities, or having discovered the secret of its processes, to utilize them in the direct production of desired materials. The problems here involved are fundamental in character and can be solved only by scientific research of the highest order. It is not a question of applied science, but a search for the underlying principles which may lead to a full understanding of the functioning of plants, and the scientific worker who achieves success in this field will not only make a noteworthy contribution to science itself, but will also make possible profound and advantageous changes in the world of industrial affairs.

No less important than the investigation of the processes of plants themselves is the study of the processes by which they have come to be what they are. In this lies one of the most fundamental problems of modern botany, a problem which involves no less than the ultimate elucidation of the laws which have determined the evolution of the vegetable kingdom. The successful solution of this problem promises results of profound significance, and advanced workers in this line of botanical activity have predicted that the time is almost at hand when our present system of classifying plants will be supplanted through "the discovery of a system which shall depict plants in their evolutionary sequence."

The botany of the future will be more and more concerned with a study of the very recent stages in the descent of the living flora, and there can be no doubt that

this line of research will be greatly stimulated by economic considerations. The efforts to bring under control those processes by means of which improved species or varieties may be originated, will lead to a much wider study of plants, and to a critical study of their relatives from widely separated situations. In arboreta and botanic gardens as well as in the great herbariums there will be brought together collections of materials for use in the investigation of genetic relationships. For the future, it is not too much to hope or expect that in proportion as our knowledge of these relationships increases corresponding advances will be made toward a solution of some of the complex problems of evolution and heredity.

It is a social obligation of the botanist to be efficient. Stein³ in his brilliant work on the philosophy of society observes that "The sense of obligation can never be derived from biology." It would seem to be self-evident that the complex facts of human life and experience can not be rightly interpreted by the same natural laws which govern the growth and development of a biological organism, although the latter view has not been without its exponents and followers. But public opinion, though long suffering, can not be depended upon to forever countenance those scientific workers whose attitude toward society is expressed by the old doctrine, "mind your own business," and whose rule of conduct recognizes no influence or appeal that lies beyond the limits of their science. The service of highest efficiency, however, will be rendered by those who through experiment, observation and generalization, succeed in dispelling the mists of shadowy suggestion which have prevented a clear view of many facts of nature, and who at

³ Stein, "Die soziale Frage im Lichte der Philosophie," 1897, s. 222.

the same time prepare the way for their widest application and utilization.

The efficiency of the scientific worker bears a very direct relation to the motives which guide him in his work. The temptation to follow the line of thought or study that for the time appears most attractive is very great and for some irresistible, and advance in one direction proceeds only until a new and more inviting path is crossed, but the scientist who pursues such a wavering course is apt to be like the aeronaut, very much in the air. The most effective workers are those who have the greatest power of sticking to a subject until every means of forcing the truth to reveal itself has been exhausted. As the necessity increases for a general attack upon the more difficult and fundamental problems, the greater is the demand for patience and perseverance in the prosecution of investigation. The homely, but expressive saying, "It's dogged as does it," which was often quoted by Darwin, illustrates a mental characteristic which has led many a man to overcome apparently insurmountable difficulties.

It is also easy to fall into the error of assuming that the collection of data is science and that whoever actively and industriously accumulates a large collection of observations on various natural phenomena thereby contributes largely to scientific progress. But the application of thought in lines that lead to definite and tangible results, and the collection of data to some useful purpose, "will always have as their guiding motive the testing of some tentative hypothesis needed for the explanation of our experience." The shelves of our libraries bear many a musty tome in which are recorded countless observations on the phenomena presented by plants, but many of these observations have little meaning for science to-day either because they

were not made with sufficient discriminating care and precision to give them scientific accuracy, or because they lacked the correlation with well established facts necessary to their interpretation in harmony with later discoveries. Other observations have remained in oblivion or conscious neglect, either because of the accident of their place of publication or because they did not appear in one of the "recognized" mediums of scientific utterance. It seems reasonable to assume that the scientific accuracy or validity of published observations or conclusions depends upon the efficiency of their author rather than upon the place of publication. Those who regard a restricted group of books and journals as a canon to which alone they look for authentic scientific utterance, and regard all others as apocryphal do but perpetuate the ancient schism between the botanists, on the one hand, and the gardeners and horticulturists on the other.

Efficiency implies not only a wide knowledge of facts, but also a breadth of view which will enable the relations between various categories of facts to be seen clearly. How the lack of understanding of the known phenomena and facts may operate to retard the diffusion of knowledge is well illustrated by the failure of contemporary scientists to understand and accept the discoveries of the early plant breeders. While the gardeners were making discoveries the importance of which was not recognized until nearly a century later, the real scientists were occupied with the recognition and classification of species. The failure of botanists to give credence to the early investigations in plant breeding has been variously explained, but we may well accept the view of Focke⁴ that "these discoveries did not fit into the idea of nature then

⁴ Focke, W. O., "Die Pflanzen-Mischlinge," 1881, s. 433.

current, for they could not be reconciled with the known facts and therefore were disregarded."

The obligation to be efficient in the avoidance of error is by no means to be taken lightly. The young writer who excused his carelessness of statement and inaccuracy of citation by saying "everybody makes mistakes" no doubt uttered a truism, but he also displayed his profound ignorance of the difficulty with which a misstatement is rectified when once it has gained a footing in literature. There is perhaps no more striking example of the strange fabric that may be woven with the warp of truth and the weft of oversight or error, than the biological principle known as Von Baer's law.

Von Baer is renowned as the originator of the theory that the embryo of every higher animal during its development passes through successive stages in which it simulates the adult forms of the lower animals in the same phylogenetic series. But Von Baer did not originate this theory, indeed he was its most vigorous opponent. What he really taught was that the embryos of different animals are similar to each other in that they adhere to the same plan of development, but through the failure of some of his contemporaries to be precise and discriminating, the ideas of another man were mistaken for those of Von Baer, and the latter was thereby placed in a false light in respect to the contribution which he made to science.

Manifestly a high degree of efficiency is just as desirable in interpreting and citing the writings of other workers, as it is necessary in planning and successfully conducting the work of experimentation, and the scientific worker who renders the best service both to himself and to his science will be as zealous in avoiding the perpetua-

tion of error as he is ardent in his search for truth.

It is a social obligation of the botanist to strive for a better organization of his science. It is not my intention to raise that much-discussed question "What is botany?" the answers to which are approximately as numerous as those who are or who think themselves botanists, although I deprecate the contrariety of opinion which exists with respect to what may properly be included in the domain of this science. Some maintain the old distinction between pure and applied science, and would exclude from the science of botany such subjects as plant breeding, economic botany and plant pathology; others think botany is largely an applied science, consisting in part of mere applications of other sciences; some conceive the science as largely restricted to one of its phases, as, taxonomy, morphology or physiology; and still others maintain that botany is not a single science but a group of distinct sciences with nothing in common except the fact that they are concerned with the phenomena presented by plants.

Segregation and specialization in various lines of botanical activity seem to be a natural process necessarily attendant upon scientific progress. Competition between these lines, each of which seeks to gain the ascendancy, and to become recognized as the true representative of the science, also seems not only natural, but necessary to normal and progressive development. There exists, however, a sufficiently close analogy between the evolution of a science and certain phases of organic development to justify the consideration of a well-established biological principle in discussions of the relative importance of different branches of the science, or the promise which they hold out of contributing most to its advancement. This prin-

ciple states that "the point of departure of the progressive lines of one period of time has not been from the terminal types of the lines of preceding ages, but from points farther back in the series." The evidence is not wanting that the new and progressive lines of botanical activity do not originate directly from the most highly specialized branches of the science, but from the more unspecialized portion. Thus arose ecology, pathology and genetics, and so doubtless will the future see the origin and development of other important and vigorous branches of this science.

It seems inevitable that from time to time each branch of the science will pass through eras of reconstruction unless, indeed, "it is assumed that the existing order is a closed system within which men can and should rationalize their conclusions, but only within that system and ever under its authority." But such a philosophy is incompatible with the modern spirit of progress, which is constantly utilizing accumulated experience in the development of new points of view and demanding a frequent readjustment of the relations existing between allied lines of investigation. The organization of the science, however, implies much more than the harmonious adjustment of relations between its various branches, or agreement as to their proper sphere of activity. It requires that botanists realize that their duties are not fulfilled by investigation alone, but that there is also incumbent upon them the obligation to give serious consideration to what for want of a better term may be called the business affairs of the science. If the great body of investigational work now in progress is to have continued growth and opportunity for unrestricted expansion, the means must be forthcoming to provide for its support, and to assure the protection of its interests. Society must be looked to

as the source of these means, and how freely they are given and what restrictions or limitations are imposed with respect to the manner in which they are to be applied will depend largely upon the degree to which there is developed in the public at large a sympathetic appreciation of the aim and purpose of the science of botany.

It is relatively easy to obtain financial support for a scientific enterprise which promises speedy returns in kind, but when the energy expended in such an enterprise is devoted solely to securing showy and immediately practical results, then does scientific education become a mere matter of merchandise and science itself is degraded to the level of a trade. Public support to scientific enterprise must be secured on some other basis than that of annual dividends. Results of great and permanent benefit to society may rightfully be expected, but they must be looked for in the better understanding of the forces of nature and their application to the promotion of human welfare, in the development of constructive habits of thought, which tends to forecast the future by an analysis of the facts of the present, and in the social progress which will be favored by a clearer perception of the relations existing between plants and man.

It is fruitless merely to affirm that more attention should be given to the claims of science, or to condemn the non-scientific classes for estimating the importance of scientific work according to its money value. I am persuaded that the much-deplored tendency to look for immediate and practical returns from scientific work is due less to crass and sordid motives than to a lack of right understanding of the manifold ways in which science exerts a beneficent influence upon the affairs of men. This disability, however, is not beyond remedy, and will be much less in evidence

when greater attention is given to the education of the individual along lines which will lead to a better perception of the real meaning of science. Organization and unity of spirit and purpose directed to the scientific education of the public are essential if practical men are to be brought to see that their interests will be furthered by encouraging scientific work and if society is to be depended upon for its liberal support.

Finally, it is an obligation of the botanist to recognize the beneficent influence of personal association. The inspiration gained by participation in the annual meetings of our scientific societies and associations is too well appreciated to need elaboration or comment. Similarly, the importance of the close personal relation between the student beginning research and his instructor is clearly understood. But it is of the possibilities which lie in the closer personal association between the junior and the senior members of this society that I would speak. It is sometimes said that the younger generation is inclined to be dogmatic, self-sufficient and somewhat disregarding of the wisdom and knowledge acquired by their elders. If this be true, it is largely because the printed page has been substituted for the more natural means of communication between individuals. But the printed page transmits very imperfectly the intangible something we call personality, that power to kindle in others the fire of enthusiasm, to develop that point of view which leads to creative thinking, and to point the path to that insight and vision which has been attained by those of riper wisdom. The younger generation needs the personal inspiration and guidance which it is within the power of their elders to give, nay, more, they stand alert and expectant awaiting the time when their natural leaders may signify their will-

ingness to give them counsel and instruction. When the senior members of this society raise the banner of wisdom and experience, and sound the assembly call, they will find their juniors quick to desert the paths which, like those in a woods, end nowhere, or which lead over the heights of purely intellectual gratification, or through the picturesque valleys of individualism, and, rallying to their standard, be content to march together along the broad road of co-operation, and united effort, which ultimately leads to the heights of progress. And then when our leaders shall approach the end of life's journey, they will have the satisfaction of knowing that although their printed works may soon be superseded or sink into oblivion, the influence of their inspiration and personality, perpetuated through their friends and fellow-workers, will endure for all time.

W. W. STOCKBERGER

U. S. DEPARTMENT OF AGRICULTURE

PREMEDICAL EDUCATION

IN Cincinnati on January 17, 1914, a conference was held under the auspices of the faculty of medicine of the University of Cincinnati. Representatives of many medical colleges and of academic institutions had been invited to be present at the meeting and to participate in the discussion upon what has been called, very widely, "premedical education." The object of this conference was to draw together the academic and medical institutions for the sake of more satisfactory preparation of students for medicine.

In opening the conference the chairman spoke as follows:

In a lecture to his students in 1821, Dr. Graves said that the practise of medicine can not be taught or learned by hearsay. Later in his introductory lecture at the opening of the session of 1837-38 he enlarged upon his former remarks, and said: "No profession requires a sounder preliminary education than ours, and in none ought education to be more studiously directed to promote

the activity and development of the mental powers, especially those connected with the habit of observation as well as with the judgment and memory." Dr. Graves realized the importance of individual judgment which must be based upon trained observation, and the dangers of the memory method which is always founded on authority. He was interested in premedical education.

This conference has been arranged for the purpose of centering your attention upon the problems of medical education, and especially of premedical education. It is evident to those of us who are medical teachers that if we are to keep medicine what it is said to be and what often it is not—one of the learned professions—we must have the assistance and the active cooperation of the colleges of liberal arts and sciences. It is to the colleges of arts and sciences that we must look for sound preliminary education for medicine.

For exercise and development of the powers of observation the sciences, physics, chemistry and biology, are most important. The laws of these are constantly applied during the whole life of the physician. Without them the study and practise of physic becomes an affair of memory instead of being one of reason. More and more the problems of medicine are coming to be chemical problems—biochemical, if you please. Biochemistry is the chemistry of the tissues and fluids of the body. These materials belong to that comparatively new class which we call colloids which are investigated most satisfactorily by physico-chemical methods. Physics and chemistry are therefore the basis of the study of the phenomena of life. There is not room in the medical curriculum for these subjects. They must belong in the premedical years—to the courses in colleges of arts and sciences, and in such colleges they must be thoroughly studied in laboratory courses. They can not be studied in lecture courses. We therefore wish to discuss the matter of satisfactory courses in physics, chemistry and biology.

It is almost unnecessary to say that with this science training, language work should not be neglected. This is especially true of English. Many of our otherwise well-trained students are deplorably ignorant of their own language. They need German and French, to be sure, but they need to be able to use their mother tongue. We wish to discuss the matter of English, German and French.

So much for the subject matter of premedical courses.

The quality of the students is just as important. The medical schools of the first grade are inter-

ested in teaching a few good students, not in teaching large classes. The United States is already overstocked with doctors. It needs no more physicians, but it needs better ones. The influence of these facts is shown already in the attempts of certain schools to limit the number of students in their classes. With good students in small classes we expect to obtain better results than we could possibly expect even with good students in large classes. Mass teaching is never successful.

Small classes of good students in medical schools will be useful in another direction. The teaching will improve. The colleges of arts and sciences can affect the character of medical teaching by sending only well-prepared students to medical schools. Good students are critical and teachers are very susceptible to criticism.

So, for the good of both colleges of arts and sciences and of medical colleges, a cooperative arrangement should have the greatest value, and such an arrangement should ultimately affect to a considerable extent the whole medical profession and, through it, the general public.

There is another important aspect in this proposed closer association of medical schools and colleges of arts. You know that, as a rule, the state standards for practise tend to lag behind—to be influenced by medical schools of the lower grades. If the colleges of arts will let it be known to their students that without two specified premedical years in college science they can not practise in the Dakotas, in Iowa, in Minnesota, Colorado, Indiana or Kentucky—that is to say that certain states will not consider them sufficiently well-educated to practise—the colleges themselves will be benefited; the medical schools will be helped; the schools of a low grade will be embarrassed, and the state boards will be stimulated to be more active in enforcing standards which will make it more possible to protect the public from the half-educated doctor.

I hope that at this conference we may be able to come to some understanding which will make it possible for us all, and for others who are not here to-day, to work toward the ends which I have suggested. It is for the benefit of all the people that we are working. The people are subject to ill-prepared doctors; they are preyed upon by quacks and charlatans. "The higher the standards of education in a profession, the less marked will be the charlatanism."

Following these remarks a series of short prepared papers were devoted to the methods

used and the scope of "premedical" courses in biology (Professor Guyer, of Wisconsin), in chemistry (Professor Jones, of Cincinnati), in physics (President Ayres, of Tennessee) and in modern languages (Professor Brandon, of Miami). Following these papers the meeting was opened for general discussion in which many members of the conference took part.

The gist of the discussion appeared to be that certain preliminary work was necessary for medicine, and that certain other preliminary work was advisable. Furthermore, it seemed that the necessary work should lie in biology, physics, chemistry and a modern language, preferably German; that a substantial enough knowledge of these sciences could not be acquired in a single premedical year; and that while it might be acquired in two years' of college work, no time was allowed in a two-year course for various studies, such as psychology, logic, economics and other advisable subjects. Also, it was said that even at the present time the average age of graduation in medicine was about 27.5 years, and that there was evidence of wasted time somewhere. Again it was urged by some members of the conference that a sharp uniformity of preparation was not a wise thing to accomplish, but that some latitude should be allowed in preparation, provided only that students who intend entering upon the study of medicine should be well equipped with a working knowledge of the fundamental sciences, and enough of the humanities to insure breadth.

Before adjournment a resolution was adopted and sent to every college represented at the conference. Later other colleges and even a few individuals were included in the list. The resolution follows:

In view of the ideas expressed in this conference,

Be it Resolved, That the representatives of the various colleges confer with their respective faculties to ascertain:

1. What courses of a premedical nature are offered by them in chemistry, physics, biology and languages.

2. What changes, if necessary, can be made to establish uniformity of essentials in premedical training.

3. Whether it is possible to reduce the total time now required to obtain the M.D. degree, by eliminating duplication of work existing in graded schools, high schools, colleges and medical schools. Your committee is of the opinion that this is feasible.

4. What arrangements are made for granting the bachelor's degree after satisfactory completion of two or three years' college work and one or two years in a Class A plus medical school, and,

Be It Further Resolved, That the action taken by the various faculties be reported to Paul G. Woolley, University of Cincinnati, chairman of the general conference committee, for tabulation, and that this committee may, at its discretion, call another general conference of the colleges interested in this movement.

(Signed) M. F. GUYER, *Chairman*,
HARRY H. HOLMES,
LAUDER W. JONES,
HENRY MCE. KNOWER,
E. L. RICE

By the time that the resolution was ready to be mailed a communication had been received from Professor Holmes, of Earlham College, which it seemed might furnish an excellent basis for faculty and departmental discussion. Accordingly, Professor Holmes' letter was embodied in a communication sent to each college. This letter was as follows:

My Dear Sir: The following remarks have come from Professor Holmes, of Earlham College, who was a member of the Cincinnati Conference on Pre-medical Education. It seems to me that these suggestions furnish a very thorough basis for the discussion of Premedical Courses in Colleges of Arts and Sciences.

"I want to suggest that our committee (or yours) map out a fairly definite three years' course of college work and persuade a large number of colleges to grant the degree of B.S. or A.B. on the satisfactory completion of this and one year's work in a 'Class A Plus' medical school. It does not meet the situation to arrange this unless nearly all the work is rather strictly outlined. Three years of general elective work could be a very poor preparation for medicine and the whole effect could be a hodge-podge not deserving the A.B. or B.S. degree. We must have a consistent major *medical and pre-medical*, for this period.

"The present 'Class A Plus' requirements of only two years college work, even though certain needed subjects are specified, cuts short the foun-

dation of chemistry so desperately needed in medicine, permits of but one modern language (because of limited time), and yet both German and French are required at Johns Hopkins and needed everywhere, and if the student attempts to take both chemistry and biology during these two years he can carry physics only at the expense of loading with three sciences at the same time—questionable in college. This plan doesn't allow for general culture.

"How much better to have the student of medicine splendidly prepared in all the fundamental essentials of his profession by three years in a college atmosphere with a little time for broader culture. Many who are not willing to spend four years for a college degree or three years as indicated would do so if they were to be rewarded with such a degree after the first year in the medical school. The standard of medicine would be raised and colleges themselves hold their students longer than at present. A few who now take four years might stop with only three, but this would be more than made up by the two-year students who remain for three years.

"Of course the state universities and some others have an arrangement for granting the B.S. to their own men after three years in college courses and one in their own medical school but what we need is a uniform standard for a large number of colleges, a standard that forces full training in the essentials. We save a year and gain much.

"Since I am not a biologist, I leave the details of that subject to be filled in by the rest of you. The laboratory time is measured, not by any credit system, for that varies, but by actual required periods of work. The electives possible should not be permitted in science or mathematics. This insures a broader training. If we get a score or more colleges to agree to this arrangement we may persuade the American Medical Association to publish a list of 'Class A Plus Pre-medical Colleges.' Why not?"

The following is Professor Holmes's schedule of the three years' work:

FIRST YEAR

Chemistry, General.—At least 72 hours of lectures.

At least 144 hours of laboratory.

Physics.—Same as chemistry.

German.—At least 144 lectures.

Mathematics.—Algebra and trigonometry, at least 72 hours.

Rhetoric.—At least 72 hours.

SECOND YEAR

Chemistry.—Must include some qualitative and quantitative analysis. At least 72 lectures and 144 hours laboratory.

Biology.—Similar to chemistry.

German.—At least 108 lectures.

Elective.—108 hours outside science and mathematics.

THIRD YEAR

Chemistry.—Must include organic: lectures, 72; laboratory, 96 hours; any other chemistry laboratory, 48 hours.

Biology.—Similar to chemistry.

French.—144 hours.

Elective.—108 hours outside science and mathematics group.

Note.—Hours refer to the entire year. The above is merely the minimum and in many cases could be increased slightly.

The results of the correspondence are interesting, not so much because so many institutions responded, as on account of the nature of the responses. As is usual in such instances those who were really interested continued the discussion, the uninterested dropped it. This again is of interest because evidently from the letters, there are some very much needed reforms.

One institution took faculty action on the resolution, and returned the following:

Be it resolved, etc.,

1. That we are glad, in so far as it is possible, to arrange our courses in biology, chemistry and physics so as to meet the admission requirements of the best medical colleges. That we are now doing this is evident from the fact that our graduates are readily admitted to the medical school of Johns Hopkins University.

2. That we will cooperate with the medical schools in every way practicable to eliminate duplication of work in college and medical school whenever such duplication exists.

3. That we do not regard a year in a medical school as having the same purpose or being in any sense equivalent to the senior year in college; that we regard the two fields of education as essentially different and distinct. We are therefore opposed to any plan whereby the bachelor's degree shall be given upon the completion of less than four years of college work.

One would only remark in commenting upon

this resolution that it all depends upon what the senior year is devoted to, whether it is or is not equivalent to a year in medical school. The senior year at Purdue in the course leading to the "B.S. in Science" is the equivalent of a medical college year and not "essentially different or distinct." Also, one might suggest that the meaning of equivalent should be stated if the paragraph is to be forceful. Moreover we shall point out later, the main difficulty in duplication is not between college and medical schools, but between college and high schools.

Other responses have come from presidents of institutions. Between these there is a world of difference. One is as follows:

The National Educational Association has a committee out on this question [reform of the whole system of public schools]. It would be undesirable for the medical schools to take any definite action in conflict with the recommendations of this committee, or with the action of the N. E. A. I think that the best we can do at the present time is to accept the public school system as it is and build on it. Referring to the recommendations of Professor Holmes, of Earlham College, I beg to say that I do not believe that it is desirable to attempt to tie down colleges as to the character of their work for their degrees; I think the colleges would resent any attempt to impose such uniformity on them. I think, further, that the consensus of opinion at our conference, including the opinion of Dr. Welch, was that such stereotyped uniformity was undesirable. No two men would probably agree on exactly the relative distribution of time between the various subjects, or on the most desirable choice of subjects themselves. I, therefore, think it will be wise to keep out of the way of such complications and difficulties that would beset us if we attempted such uniformity.

The writer of this letter misunderstands Professor Holmes schedule, which was suggested as the form of a course. In carrying out such a scheme no limit is placed upon the individuality of teacher or student. The "relative distribution" of time is one thing, the essentials of premedical teaching is another. There is a *least* time in which the essentials can be covered by the average stu-

dent and the schedule is made for the average. Allowance is always, I hope, made in colleges at least for the brilliant students for whom no schedule can ever be made.

Another presidential letter follows:

I will answer first the questions formulated by your committee.

1. We offer everything required in the regular premedical course, that is, we fulfill the two-year requirements of the American Medical Association and besides this have just adopted an agreement with Western Reserve Medical College for a combination course—three years at our own school and four years at Cleveland.

2. I believe that the only way in which uniformity of essentials in premedical training can be obtained is by the adoption by the American Medical Association of standard requirements for a three-year course. Our faculty believes that the course suggested by Professor Holmes, of Earlham College, is an excellent one with possibly one or two minor additions. We are, at present, giving everything in this course and should be glad to publish in our catalogue a regular three-year premedical course if sanctioned by the Medical Association.

3. Our faculty believes that duplication of work is practically unavoidable in view of the quality of teaching done in certain secondary schools in the country. We believe that the best way to get efficient teaching in these schools so that work done there need not be duplicated in college is to increase considerably the requirements for those who wish to teach in such schools. Our idea is that the present system of examination required of teachers in many subjects tends to an unwise dissipation of energy on the part of the candidate. We should advise much stricter requirements in that particular line in which the candidate wishes to teach, with a thorough examination, and, at the same time, elimination of a dozen or more odd subjects now required in Ohio teachers' examinations. We believe that this method would make for the securing of well-prepared specialists in the various departments of secondary schools.

4. As stated above, we have made formal arrangements for a combination course only with Western Reserve Medical School. We are, however, prepared to enter into the same combination with any school in the A plus class of the American Medical Association. Our requirements are: Three years spent in residence at . . . ; the pass-

ing of at least 96 semester hours of work here, with a total of 128 hours for graduation; also the completion of the necessary major and minor requirements in any of the courses laid out in our catalogue. If these conditions be satisfied, we will give a Bachelor's degree to students in combination course after one year's work in an A Plus Medical School.

I proceed now to answer your second letter containing the course of study proposed by Professor Holmes, of Earlham College.

I may say at the outset that our faculty is heartily in sympathy with Professor Holmes's ideas and believes that the establishment of a definite premedical course with a list of approved premedical colleges would be of extreme value.

As stated in answer to your first letter, we are perfectly willing to adopt combination courses giving a college degree after three years spent with us and one year in an A plus medical school, provided that the student has three years of residence in . . . ; passes 96 hours of work here and a total of 128 hours for graduation and provided also that he fulfills the major and minor requirements of one of our regular courses. We already have made such an arrangement with the Western Reserve Medical School.

Our faculty begs to signify its approval of a three-year schedule as submitted by Professor Holmes with the following suggestions: That the various colleges be allowed a certain latitude as to the year in which certain subjects are given. Our courses in physics, for instance, are not open to freshmen and could not be taken in the first year. Possibly a general statement of requirements in each subject would meet more general approval than a definitely laid out program year by year and would allow various colleges a little more latitude in arranging courses. Our faculty is also unanimous in its feeling that at least 103 semester hours of psychology should be required in every premedical course, since this subject is practically indispensable to a well-equipped medical man of to-day.

With the above suggestions, we are heartily in agreement with the proposed plan and are willing to adopt it should it receive the sanction of the American Medical Association.

In this letter the quality of teaching in the secondary schools is mentioned. This I shall comment upon later. I wish, however, at this point to emphasize the method suggested for improving the teaching ability and therefore

the quality of the teaching in secondary schools. The question of psychology is also touched upon. Certainly a course in psychology should be a prerequisite for graduation in medicine. Without it there is little value in courses on mental diseases, but any introductory course should be supplemented later by a brief course in experimental psychology, and, for those who desire to go more deeply into psychiatry, a thorough course should be offered.

Among the letters which have been received, there are two from deans which deserve quoting. The first begins with an outline of the work offered for the degree B.S. It then says:

We have had one case granted the privilege of being absent during the senior year, counting the work of the medical college as equivalent to our senior work. It did not appeal to us very strongly for several reasons. First, the difficulty of getting the reports of standing at proper times and controlling thesis work. This, of course, was a minor difficulty, but none the less annoying. Second, was the fact that high-grade students are not as a rule interested in such a scheme. With us it has apparently applied to an unstable group of students, restless under university restrictions and apparently constitutionally unable to remain in any institution for more than a year or two. Such men are neither good representatives of the college from which they go nor desirable candidates for the medical college in which they matriculate.

May I suggest another possible solution? Suppose we realize that four years is not a divinely appointed length of time for either baccalaureate or medical degree. Suppose we recognize the fact that the degree represents a definite amount of work satisfactorily done. Suppose that we also allow men of sufficient mental strength, industry and eagerness to do the work in three years, either in the college or in the medical school. If this were done, would not the same, if not a better, result be reached? Certainly high-grade men would be rewarded for their ability and industry and a short cut to two degrees would not be offered to all sorts of candidates. Whether in university or in medical college there seems no good reason why a man should not have one or two ways of obtaining credit, either by taking the subject or by examination.

As it stands, all of our courses of study are arranged for the average man, and the average intellect of five hundred people does not come very high. An easy inference is that many bright men, both in the university and in the medical college, are merely marking time. A method such as I suggest has nothing against it save the sanctity we have thrown around the four-year idea of the amount of work required for a degree. If requirements for a degree were measured in quantity and quality of work, instead of in time, many of the difficulties of which we complain would disappear.

I have no sort of objection to the plan as outlined. It is substantially that put in practise in 1895 by a number of institutions maintaining premedical courses by private arrangement with medical colleges. I will present the communication to the faculty for consideration and action, but I doubt if we would care to advertise a three-year-in-and-one-year-out-degree. That a baccalaureate degree should not be given for work done in absentia is almost a necessity if the degree is protected.

A scheme which will give the man of exceptional ability a chance would appeal to me. At present our educational systems favor the average man and penalize the exceptional man. We spend too much time trying to put a polish on a buckeye which should be given to mahogany. However, count on me to attempt to put anything through the committee agrees upon. I feel it is about time we are getting down to fundamentals in this joint between university and professional schools. If the fundamentals are not such, then what I have said is without significance; but being in close contact with medical and university education makes me absolutely certain that any attempt to shorten the time before the degree of M.D. can be secured, by elimination of English and other cultural studies, is basically wrong and foredoomed to failure.

This letter is to me an exceptionally strong one, for I feel that it hits the nail exactly and evenly on the head. The "divinely appointed length of time" occupied in the various divisions of an individual's educational career needs consideration. Let us by all means measure a man first by the quality of his work, and second by the quantity, and then help him in the way he should go, and if he deserves it, if he is mahogany—polish him; if he is a nut—give him what polish we can

spare from the finer work, or plant him in another soil.

The second letter that I wish to quote in this connection is from a medical dean of a university where two courses are offered in preparation for medicine, a one-year and a two-year course, the latter leading with additional medical years to the degree B.S. This letter says that when conditions change, they in that university are prepared to make a rearrangement which will, the dean believes, be an improvement. And further,

The most serious problems with us arise from the inefficiency of the high schools, especially in the elementary science and language courses. So few of our high schools (and I think the conditions are essentially the same throughout the greater portion of the South) give acceptable courses in science and modern languages that for practical purposes they may be left out of consideration. The result is that the college courses must necessarily be more elementary in character and of lower grade than they otherwise should be. A course in general chemistry, for instance, arranged for students who have had in the high schools an elementary course in general chemistry with laboratory work would be of a much higher grade than a course arranged for students without such preliminary training. So long as this condition exists there will be very little improvement in "chemistry 1" or "zoology 1" or "physics 1." The weak elementary courses strike at the foundations of a sound science training and so long as chemistry 1 is weak, chemistry 2, 3 . . . x will not be all that we expect of them. The problem with us is therefore the strengthening of chemistry 1.

In the absence of adequate high school courses one obvious remedy is the introduction into the college curriculum of a group of elementary science courses supplementary to the high school course. This has been done in the modern language department here. Such an alternative will necessitate an additional "college year" which for many reasons is objectionable. The college should do less rather than more of the high school work.

This letter calls attention to the fact that high schools offer courses in physics, chemistry and biology, and that they offer incomplete courses, which, however valuable they may be to the individual who is not going to study medicine, waste the time of the one who

is going to. The remedy is obvious. The high school should limit its incomplete scientific work for the many who do not expect to follow scientific courses in college, and either offer complete courses for those who do expect to do scientific work, or leave the introductory science to the college. Such a program would mean a certain amount of individual work along the lines of vocational guidance, a thing which is being done more and more in preparation for the trades, and with excellent results. It has not been applied to the professions. As the age of graduation has increased it has become evident that some method must be devised which shall save the time of the student in order that he shall be prepared for his life work before he reaches senility. I have already called attention to a possible method of applying guidance methods to pre-medical students in high school and grammar school, but so far as I know the experiment has never been made.

There is a method which might be used certainly in college and even in high school. My attention was called to it by my colleague, Professor Fischer, who designated it as the Missouri plan. It is based upon a system which allows a student who does excellent work in a subject additional credit. The following extract from the University of Missouri Bulletin 1913-14 will elucidate the method:

In order to encourage students to do the best work of which they are capable, the faculties of the college of arts and science and of the school of education credit their work in proportion to the grade received, thus enabling the most industrious students to graduate in three years. For each recitation hour for which the grade of excellent is recorded, the student will receive thirty per cent. additional credit. For each recitation hour for which the grade of superior is recorded, he will receive fifteen per cent. additional credit towards graduation.

The faculty further recognizes that those students who are inferior to seventy-five in a hundred, but whose work is not estimated by the teacher as a complete failure, are entitled to some credit. Students will, therefore, be given four fifths of the normal credit towards graduation for each recita-

tion hour for which the grade of inferior is recorded.

In order to do entire justice to the needs of the students coming to the University of Missouri, the faculty adopts the method of instruction to the students of average ability. Those who are of somewhat less ability will thus receive some benefit from the instruction and some credit. Those who are of superior ability and will devote their best energies to their work will accomplish much more than the average student, and will be given for this, not empty honors, but recognition of their accomplishments by additional credit.

There is one letter which attacks the general elective system. In this letter the writer says that he has been opposed to the free elective system. His "contention has been that the undergraduate should be free to select his own aim, such as law, medicine, commerce or engineering; but that we should prescribe the program of work for its attainment." "Your letter," this professor says, "gives one a new incentive for a renewal of the contest; but this time for a three-year program."

Personally I believe in this stand on the subject of electives. I believe there should be a very definite program outlined for each student who has chosen his field—not a time schedule, but a subject schedule—in which there shall be some space for electives. And I believe, as I have said elsewhere,¹ that the earlier in the educational career of a student this schedule can be put in force, the better. There is too much to be known in all professions to waste time in indeterminate grazing.

The letters from professors, all from heads of departments, are as strong as those already quoted. In almost every instance the writers insist upon thoroughness and upon essentials rather than time consumed. Every one insists (though indirectly in certain cases) that three years of college work is the least in which the average man can obtain the essentials of medical preparation and the other things which, while not essential for medical practise, are essential for breadth and wide understanding. It was this thing that I have called breadth which made our fore-

¹ *Lancet-Clinic*, 1914.

runners in medicine what they are to us. Without a wide and deep social vision the doctor of the future will not be what he should be. Medicine is becoming more and more social. Its function is becoming more and more one of prevention. And a deeper insight into human nature, and a keener understanding of all the sciences, particularly the biologic, will be demanded of the man who will succeed.

PAUL G. WOOLLEY

UNIVERSITY OF CINCINNATI

*PROFESSOR THEOBALD SMITH AND A NEW
OUTLOOK IN ANIMAL PATHOLOGY*

THE recent announcement of an additional endowment to the Rockefeller Institute for Medical Research, for the establishment of a department of animal pathology, marks a far-seeing and helpful recognition of the importance of a phase of research now scantily supported, yet full of promise for the physical and economic welfare of mankind and the well-being of animalkind also. But as the success of such an undertaking is after all more a matter of men than of money, the news that the projected department is to be organized and conducted by Professor Theobald Smith, of Harvard University, is of the happiest augury.

Though long in the foremost rank of the notables of science in America, the work of Professor Smith has not often secured, or suffered, popular exposition. But he has had the uncommon satisfaction of seeing, many times, the lines of thought and research which he has opened lead sooner or later to far-reaching theoretical development and practical achievements.

Thus while Dr. Smith was yet a subordinate in the Bureau of Animal Industry in Washington, he had occasion to study the Texas fever of cattle, then the cause of great economic loss to the farmers and cattle-men of that as well as other states, and of countries the world over. He found at last that the disease was incited by a protozoan parasite so small that it found a spacious abode within the purlieu of a single red cell of the blood, which it ruthlessly destroyed.

Smith and Kilborne announced also that this piroplasma, as it was called, is conveyed from animal to animal through the intervention of a cattle tick in which the protozoan undergoes a developmental cycle upon which the perpetuation of its kind depends. They further learned that cattle recovered from the fever had become immune, and though well, might indefinitely carry the piroplasma in the blood and be a perpetual source of infection for cattle fresh from another district.

This surprising, unprecedented, and, as it seemed to many at the time, unnecessarily complex and rather preposterous mode of infection made good its claims, and Texas fever leads the line of infectious diseases in men and animals, in which some insect acts as intermediary host and sole conveyancer of infective microbes from their sources to fresh victims. Thus in malaria and in yellow fever it is the mosquito which is to blame, and its suppression in any country insures virtual emancipation from these diseases. Thus have Cuba and Panama been rescued, and the way is open for the control of other tropical infections in other lands. Thus also the infective agents of plague and typhus and other communicable maladies are harbored and dispersed by insects which are the vulnerable links in the chain of infection often most easily broken through sanitary control.

The story of all these practical achievements in disease prevention through the knowledge and control of insect pests, leads back twenty years and more to the hot and gloomy garret in Washington, then the laboratory of the Bureau of Animal Industry, and to Dr. Smith's parasitic cattle tick harboring its own invisible protozoan parasite. And Texas fever no longer exacts its toll from man or beast; or if it does it is the man's fault. These immune cattle, bearers of the, to them, innocuous parasite, head the procession of "carriers" of infective agents, in which humans are now known to hold a conspicuous place, and are the bugbears of preventive medicine to-day.

Almost as soon as Koch had shown the world how easily and accurately to cultivate bacteria, more than thirty years ago, in the very

earliest of the eighties, the laboratories got intensely busy in the search for new species of germs; and as fast as forms were discovered which incite disease, the knowledge of how they look and what they do and how they may be restrained or destroyed was turned to the service of man and beast.

But the researches were not long content to spy upon the performances of the germs. What the living threatened body does to protect itself against them when once they gain a foothold became a subject of wide and fruitful inquiry. So the facts and doctrines and guesses relating to immunity and to infection, either natural or acquired, came to the front.

Pasteur had got some wonderful results in the experimental conference of immunity to infection, by gradually adapting animals to disease-inciting germs, which were living, but whose virulence and potency had been artificially reduced. It was then supposed that only the subtle action of the living germ could conjure forth the remarkable protective power apparently created in artificial immunity. Many others were at work on these and kindred lines; Dr. Smith among them. But he noticed, and was the first with Salmon to announce in 1886, that animals could be immunized not only by living germs but by cultures of these which had been sterilized and every vestige of life destroyed.

This announcement did not seem to start even a ripple in the bacteriologic pool. But the thing was in the air. There were many busy workers, and sooner or later such a record helps more than is commonly realized another explorer who is heartened to find his pathway not quite untrod.

Very soon it had been shown that immunity to diphtheria may be secured in animals not only by the living germs, but by the sterile products of their life processes. Thus with the names of Loeffler, Behring, Roux, Yersin and many others, opens the story of diphtheria antitoxin and its marvellous benefactions to mankind.

And so again, every horse which is turned to the uses of suffering mortals and gets his dosage of sterile diphtheria culture broth for

the manufacture of antitoxin, is but another exemplar of the principle which first crystallized in the light of the response which Dr. Smith's pigeons made to the sterile hog-cholera bacillus cultures, at that early day, close to the dawn of the bacteriologic era in biology and medicine.

Dr. Smith has devoted a great deal of time and energy to the study of diphtheria and other antitoxins, both as professor of comparative pathology at Harvard and as the director of the antitoxine and vaccine laboratories of the Massachusetts State Board of Health. As is the case with most acute observers in these uncharted fields of bacteriology and immunity, he has encountered many striking phenomena which the lore of the time had not satisfactorily classified or accounted for. One of these carries a little story.

When Ehrlich was in this country in 1904, Professor Smith called his attention to the singular fact that guinea-pigs which he was using to test diphtheria antitoxin, sickened and died upon being injected with normal horse serum several weeks after they had been injected with diphtheria antitoxin. Guinea-pigs usually do not mind normal horse serum at all. Such an extraordinary sensitiveness to normal serum, following earlier injections seemed something new and unaccountable, and when Ehrlich got back to Frankfort he gave the problem to Dr. Otto, who labored with it and presently wrote a paper on what—with an attitude of undismay toward stately adjectives that is characteristically German—he called the “Theobald Smithsche Phänomenon.” Nowadays the yearly lists of the achievements of research in infection and immunity fairly swarm with studies on “anaphylaxis,” a phase of immunity of which Professor Smith's guinea-pigs afforded one of the first recorded examples.

In the early days of bacteriology Dr. Smith called attention to the value of a bent glass tube, closed at one end, such as was already in use by the chemists, for the purpose of cultivating many types of bacteria and studying their biological characters. This is of especial value in the culture and study of the class of

bacteria known as anaerobic, whose activities are intolerant of the presence of oxygen. "Smith's culture tube" has long been held in high esteem in the outfit of the bacterial laboratory.

But as early as 1890, Dr. Smith called attention to the fact that anaerobic bacteria are exacting not only in their relations to oxygen, but in their food requirements also; and he suggested, and proved, that attention to the latter gave promise of important results in the study of this class of germs. He then, and has repeatedly, urged that the addition to the fluid media in the tubes in which such organisms are commonly grown, of small pieces of sterile animal organs, such as the kidney, fulfil the required nutrient conditions. The repeated hint remained practically unheeded for some twenty years. Then through its adoption Noguchi, at the Rockefeller Institute, was able for the first time to cultivate the spirochete which is the inciting agent of syphilis, as well as several others of its class which have hitherto resisted all the wiles and blandishments of the most accomplished bacteriologists, in the framing of the conditions of culture and the tender of food. With these cultures available Noguchi has made practicable and safe a test—the luetin test—for the most subtle and obscure forms of syphilis. Thus the way is now open for the more ready detection of this sinister disease, for the study on a solid basis of the conditions under which it is manifested; how its protean characters are determined; and what rational methods for its cure may be conducted. Similarly, scarcely more than a year ago, Flexner and Noguchi, by an adaptation of Dr. Smith's long ignored suggestion about the food requirements of anaerobes, have been led to the discovery of the nature of the virus of infantile paralysis, isolating it in cultures maintained through many generations and clearing the way toward a hopeful outlook for the prevention and perhaps the cure of this pitiful malady.

One of Professor Smith's striking achievements is the establishment, through long and patient studies, of a type of the tubercle bacillus which has become especially adapted to

cattle and now is known as the "bovine type" of the tubercle bacillus. The delimitation of this organism and its differentiation from the human type have made possible a series of exact researches by others on the frequency of the occurrence of the bovine bacillus in man. And thus to-day those who are engaged in the long and stubborn fight against the spread of tuberculosis are on firm ground when they enter the field of meat and milk contamination, to determine the measures which must be taken to safeguard them at their source.

These are some of the landmarks in Dr. Smith's achievements during this quarter of a century of incredible activities on every hand, in the discovery of microbic disease incitants, of the things they do, and the reactions of those individuals of the higher sort who in the vicissitudes of life may become their hosts and their victims.

As the eye ranges over the stately bibliography which marks these years of Dr. Smith's scientific activities, it rests upon many titles with stories in them, of a period or a halting point, in the growing knowledge of disease and its incitants, upon which the author's wide range of thought, his unventuresome sagacity, and breadth of vision have cast helpful and inspiring light.

While Professor Smith gets down to the humdrum details of exact research and record when it is necessary—and it often is necessary in all the ups and downs of the common road of fruitful biological research—the quality which is perhaps most characteristic is the larger view impressed upon all his problems. The biological point of view, if the reader please, in which the individuality of the living thing Dr. Smith sees bears in every feature the marks of its heredity and environment. The tubercle bacillus, for example, is to him not something which has just happened, in the human and animal kind. The bacillus gets his day in court, and is as much a part of the scheme of things as is his more imposing host. What happens when they meet in a many-sided conflict of adaptation, and the problems which gather about it are to be

solved only by sustained attention to all its many aspects.

This larger vision, the ability to set the pace on a high plane, the capacity for work, the power of constructive leadership—these are the qualities which lead those who know Professor Smith and his achievements to rejoice that he is now to center his activities in a field so full of promise as is animal pathology to-day; and this with the opportunities which the Rockefeller Institute affords those who share its aims, to carry forward their chosen work unhurried and unhindered.

T. M. P.

SCIENTIFIC NOTES AND NEWS

DR. S. J. METZER, head of the department of physiology and pharmacology of the Rockefeller Institute for Medical Research, has been elected president of the Association of American Physicians in succession to Dr. Simon Flexner.

At its annual meeting, held on May 13, the American Academy of Arts and Sciences voted to award the Rumford Premium to William David Coolidge for his invention of ductile tungsten and its application in the production of radiation.

THE Franklin Institute, Philadelphia, on May 20, presented its Elliott Cresson medals to Dr. Edgar Fahs Smith and Dr. Orville Wright. Addresses were made on "Scientists from the Keystone State," by Dr. Edgar Fahs Smith and on "Stability of Aeroplanes," by Dr. Orville Wright.

HONORARY degrees are to be conferred by the University of Glasgow on Dr. Archibald Barr, late regius professor of civil engineering and mechanics in the university; Colonel Sir William' B. Leishman, F.R.S., professor of pathology in the Royal Army Medical College, and Sir Ernest H. Shackleton.

ON May 4, a company of men and women, forest lovers, gathered in Harrisburg, at an informal luncheon, to present a testimonial to Dr. J. T. Rothrock on his retirement from the Pennsylvania Forestry Commission. There were sixty-five present, among whom were

Governor J. K. Tener; Mr. John Birkinbine, president of the Pennsylvania Forestry Association; Mr. A. B. Farquhar, president of the Pennsylvania Conservation Association; Mr. J. Horace McFarland, president of the American Civic Association; President H. S. Drinker, of Lehigh University, president of the American Forestry Association; Mr. C. F. Quincy, chairman of the executive committee of the American Forestry Association; Professor J. A. Ferguson, director of the forestry department, Pennsylvania State College; Hon. R. S. Conklin, commissioner of forestry, Pennsylvania, and Dr. S. R. Dixon, state health commissioner of Pennsylvania. The governor presented in behalf of two hundred and fifty donors, a beautiful loving cup, and Mr. Farquhar, Dr. Drinker and Mr. Conklin spoke of Dr. Rothrock's work and personality. Dr. Rothrock spoke feelingly in reply.

At the annual meeting of the Boston Society of Natural History the following officers were elected for the ensuing year: *President*, Charles Sedgwick Minot; *Vice-Presidents*, Robert T. Jackson, Nathaniel T. Kidder, William A. Jeffries; *Secretary*, Glover M. Allen; *Treasurer*, Edward T. Bouvé; *Councillor for two years*, Alfred C. Lane; *Councillor for three years*, Thomas Barbour, Henry B. Bigelow, Miss Cora H. Clarke, William G. Farlow, George H. Parker, John E. Thayer, Charles W. Townsend, William F. Whitney. Reports were made on the work and progress of the year and an illustrated paper was presented by Dr. Hubert Lyman Clark on his experiences as a member of the Carnegie Institution's expedition to Torres Strait and the Great Barrier Reef of Australia. The two annual Walker Prizes, awarded for the best memoirs submitted on subjects in natural history, were voted as follows: a first prize of \$60 to Miss Marjorie O'Connell, A.M., of the department of geology, Columbia University, for her essay on "The Habitat of the Eurypteryda"; and a second prize of \$50 to William J. Crozier, of Cambridge, for his essay on "The sensory reactions of *Holothuria surinamensis*."

DR. ZENTARO KAWASE, professor of forestry in the University of Tokio, Japan, is in America to make observations in original forest areas, especially those in the southern Appalachian Mountains.

DR. E. L. EKMAN, assistant in the botanical department of the National Museum at Stockholm, recently visited the New York Botanical Garden for nearly two weeks on his way on an exploration for two years to Santo Domingo and the state of Pernambuco, Brazil.

MR. A. N. HALL has been appointed government curator of the ancient monuments of Rhodesia. His headquarters will be at Great Zimbabwe, but he hopes to spend four months of each year in examining or searching for other remains.

DR. A. G. WEBSTER, professor of physics, Clark University, gave on May 8 a lecture on "Sound and Its Measurements," before the Columbia chapter of Sigma Xi.

ON April 23 and 24, Dr. Oscar Riddle, of the Carnegie Institution, lectured before the Sigma Xi Societies of Indiana University and Ohio State University on "The Determination of Sex and Its Experimental Control."

HIRAM PERCY MAXIM lectured on "The Annihilation of Noise" and demonstrated the Maxim silencers before the Middletown Scientific Association at Wesleyan University on May 12.

PROFESSOR CHARLES H. HASKINS, dean of the graduate school of Harvard University, delivered the annual address before the Zeta chapter of Phi Beta Kappa and the student body of Oberlin College, on May 8, on the subject "The Medieval Scholar."

THE retiring president of the Geographic Society of Chicago, Professor Henry C. Cowles, gave on May 8 before the society an illustrated account of his observations and experiences in guiding a party of distinguished plant geographers through the western United States in the summer of 1913.

THE Halley lecture for 1914 will be delivered at the University of Oxford by Colonel C. F. Close, director of the Ordnance Survey, on

May 20. Subject, "The Geodesy of the United Kingdom."

THE celebration of the seven hundredth anniversary of the birth of Roger Bacon will be celebrated at the University of Oxford on June 10.

MR. ROBERT KAYE GRAY, an electrical engineer, active in the promotion of scientific research in England, died on April 28, at Brighton, at the age of sixty-two years.

M. PAUL LOUIS TOUSSAINT HEROULT, known for his work with aluminum and the electric furnace, died on May 10, aged forty-one years.

THE Liverpool School of Tropical Medicine plans to establish a permanent laboratory in Sierra Leone for the purpose of carrying on research work.

THE old chateau at Les Eyzies (Dordogne) has been purchased by the French government and will be converted into a museum of prehistoric archeology.

Nature calls attention to an arrangement now established at the Royal Botanic Gardens, Kew, whereby a competent guide accompanies visitors on week days through the gardens and explains the objects of botanical interest. A small charge is made for the services of the guide, 6d. for each person attending a **morning** tour, and 3d. for each person attending an afternoon tour. The present arrangements are of the nature of an experiment, and their continuance beyond September next will depend on the extent of the public demand for the services of the guide.

WE learn from the *Journal* of the Society of Arts that preliminary steps have been taken for the establishment of an institute of oceanography for the study and exhibition of marine life and products at Ste. Adresse, a suburb of Havre, overlooking the Bay of the Seine. Plans for a handsome building, about 275 feet long and 40 feet wide, have been drawn up by a well-known Paris architect. It will be constructed in a park of 323,000 square feet. It is estimated that the building and equipment will cost about \$150,000. It is hoped to have the building completed and opened in time

for the meetings of the scientific congress to be held in Havre in the autumn of 1914. The most interesting feature of the institute will be an aquarium which will offer instruction and entertainment to the inhabitants of Havre and the vicinity, as well as to the numerous tourists who visit the district.

THE University of Chicago Press has assumed the American agency for the *Internationale Monatsschrift für Anatomie und Physiologie*, published at Leipzig by Geirg Thieme. Professor Robert R. Bensley, of the department of anatomy in the University of Chicago, has been made American editor of the journal. The University Press has also announced the addition of two journals to the list of nine it publishes in America for the Cambridge University Press, England. The journals are *Annals of Applied Biology* and *The Annals of the Bolus Herbarium*, the former of interest to workers in entomology, plant disease, diseases of animals, and forestry, and the latter dealing with the flora of South Africa. In addition to these twelve journals of research for which the University of Chicago Press is the American agent, it now publishes itself sixteen other journals.

THE department of archeology, Phillips Academy, Andover, Mass., has conducted research work in the state of Maine for a number of years. In June, it is planned to send an expedition of ten or eleven men from the headwaters of the St. John River to its mouth—a distance of over three hundred miles. The expedition will then proceed to the head of Mattawamkeag stream and travel south some fifty miles, and then explore the Upper Grand Lakes, the Lower Grand Lakes and the Ste. Croix basin. A side expedition will move eastward into central New Brunswick. The total distance traveled in canoes will be over six hundred miles. The object of the expedition is, so far as possible, to trace the limits of the so-called Red Paint Culture, and to map prehistoric and historic sites in the regions visited. Excavations will be undertaken where it seems advisable. In case large or important sites are discovered the expedition will work out such in more or less detail, and if neces-

sary, will postpone further reconnaissance until next year. The archeological material discovered, together with observations on historic sites, should enable students to better understand the relationship between the various eastern cultures, and may shed some light on prehistoric migrations. The plans have been approved, and in the absence of the director of the department, Dr. Peabody, in Europe, Curator Moorehead will conduct the expedition. Most of the members of the survey have seen previous service in Maine, and it is hoped that important results will be obtained. Francis B. Manning, of Harvard, will be first assistant; and Ernest Sugden will act as surveyor. The total number of Indian sites mapped by the department in Maine in past years is over two hundred. About 5,300 stone and bone artifacts have been taken from excavations at various points. The department is compiling a bibliography of references to Maine Indians. At present there are over three hundred titles, and the work is not completed.

DR. J. E. WALLACE WALLIN, who since the winter of 1912 has occupied the position of professor of clinical psychology and director of the psychoeducational clinic in the school of education of the University of Pittsburgh, has been appointed to the position of director of the psycho-educational clinic in the St. Louis public schools. The clinic will be organized at the beginning of the next school year. It will be located on the grounds of the Harris Teachers College, with which institution it will be closely affiliated. Lecture courses on abnormal children by the director will be offered in the extension division of the college. Students may matriculate in these courses whether or not they reside in the city of St. Louis. The clinic will be organized as an independent bureau in the educational division of the school and not as a minor division of the department of school hygiene or medical inspection. But it will work in close cooperation with the latter department. The clinic will exercise administrative control under the regulations of the superintendent's office over the examination, classification, education,

placing and transfer of the mentally exceptional children in the public schools. The actual supervision of the work in the special classes will be done by a special supervisor working under the direction of the clinic. St. Louis has already segregated about 500 pupils in special classes, and it is expected that the number will now rapidly be increased to at least 1,000. Each child will be given a psychological, sociological, pedagogical, hereditary and medical examination. It is expected that a staff of assistants commensurate with the growing needs of the clinic will gradually be organized, and that, eventually, the clinic organization will include a bureau of vocational guidance. The clinic aims to serve as an educational, social and vocational clearing house for the community. The St. Louis authorities have carefully studied the situation and believe they have effected the best form of organization, linking the clinic, on the one hand, with the training school for teachers, and, on the other hand, making it an integral part of the educational division, with supervisory control of the special classes.

ALMOST every conceivable use to which land may be put is represented in the permits reported by the forest service for special projects on the national forests. Some of the uses shown range, alphabetically, from apiary through brickyard, cannery, cemetery, church, cranberry marsh, fox ranch, marine railway, rifle range and turpentine still, to wharf and whaling station. There are 15,000 permits in force for such special uses, which are distributed geographically from Alaska to the Mexican line, and east to Florida. This figure does not include any of the 27,000 permits in force for grazing cattle and sheep on the forests; nor the 6,000 transactions for the sale of timber, and the more than 38,000 permits issued last year for the free use of timber by settlers, miners and others in developing their homesteads and claims; nor the nearly 300 permits for water power development. California led all the national forest states in the number of these special use permits, followed by Arizona, Colorado, Montana and New Mexico in the order named. The largest single class of permits was for special pas-

tures or corrals, to be used for lambing grounds, shearing pens, and the like. Next came rights of way for conduits, ditches and flumes, practically all of these being free. Various agricultural permits come third, telephone lines fourth with more than a thousand permits for 6,500 miles of line, and drift fences for the control of grazing animals, fifth. In both of these latter classes, too, practically all of the permits are free. Reservoirs for which more than 600 free permits were issued for the occupation of more than 100,000 acres come sixth. The rest of the uses are not classified though there are a large number of apiaries, camps, summer hotels and schools. The use of the government's lands for schools is given free; for hotels a charge is made. The principle which governs the charge is based, according to the forest service, on whether or not the use of the land is sought by the permittee for a commercial purpose. If it is the intent of the user to make money from a resource which belongs to the whole people, the service holds that he should give a reasonable return for that use. If, on the other hand, farmers want to use government land for their own telephone lines, irrigation works and schools, the government gives them that use without cost.

INTEREST attaches to the study of the fossil floras of the Arctic regions, for they indicate climatic conditions very unlike those now existing there. In place of the present almost perpetually frozen soil which supports but a handful of depauperate plants, the conditions from at least late Paleozoic to middle Cenozoic geologic time made possible at least during certain periods, an abundant and luxuriant vegetation, consisting of ferns and palm-like plants that could grow only in a mild and probably frostless climate. Although these lands are now so inhospitable, and hence but rarely visited, an astonishing amount of information concerning their fossil floras has been accumulated, and to this knowledge Alaska has contributed its full quota, says F. H. Knowlton, a paleontologist of the United States Geological Survey, in a short paper on the "Jurassic Flora of Cape Lisburne," just published as Part D of Professional Paper 85.

The fossil plants described by Mr. Knowlton were collected by A. J. Collier, a geologist of the Survey, while engaged in the study of the coal resources of the Cape Lisburne region. The coal deposits are extensive and are the only mineral resources of the region known to be of commercial importance. A little mining has been done by vessels short of fuel, which occasionally lie off shore and load on a few sacks of coal. This, however, is a rather dangerous practise, as there is no harbor. Cape Lisburne is the bold headland which marks the northwestern extremity of a land mass projecting into the Arctic Ocean from the western coast of Alaska between latitudes 68° and 69°. It lies 160 miles north of the Arctic Circle, about 300 miles directly north of Nome, and is the only point in Alaska north of Bering Strait where hills above 1,000 feet in height approach the sea. The Jurassic section to which the name Corwin formation has been given is said by Collier to consist of shales, sandstones, conglomerates and coal beds. Fossil plants occur in the shale beds wherever they have been examined. This formation reaches the enormous thickness of over 15,000 feet and contains 40 to 50 coal beds which range in thickness from 1 or 2 to over 30 feet, ten of them being 4 feet thick and suitable for mining. The various beds aggregate at least 150 feet of coal. Mr. Knowlton correlates the Jurassic flora of Alaska with that of eastern Siberia and concludes that the land connection between North America and Asia at this early period of the world must have been practically continuous. In reviewing the character and geographic range of Jurassic floras, especially as developed in Arctic and Antarctic regions, he states that the wide areal distribution of Middle and Upper Jurassic floras has long been one of the marvels of plant distribution. The living flora of to-day, of course, affords many individual examples of wide distribution, such as those found throughout the tropics of both hemispheres, and others, chiefly weeds, that have, largely through human agencies, spread widely over temperate lands, but altogether these plants form but an insignificant part of

the whole flora, whereas in Jurassic time a large percentage of the whole flora was practically world-wide in its range. Even Cape Lisburne is by no means the northern limit of this nearly tropical vegetation; it has been found, preserved in the rocks, 180 miles northeast of Cape Lisburne.

UNIVERSITY AND EDUCATIONAL NEWS

MRS. HELEN H. LE FEVRE has made to New York University a gift of \$10,000 in memory of her husband, the late Dean Egbert Le Fevre. The gift is in the form of a trust to be known as the Dr. Egbert Le Fevre Deanship Fund.

The trustees of the University of Chicago have announced the appointment of a committee to decide on the date and character of the celebration of the twenty-fifth anniversary of the founding of the University. The University of Chicago was incorporated on September 10, 1890.

The New York State College of Forestry has announced plans for the establishment of a course in paper and pulp making.

It is stated in *Nature* that the British chancellor of the exchequer in explaining his budget proposals said that the education grant is to be reconstituted on the principle of making a distinction between the richer and the poorer areas, and between the areas that spend much and those that spend little on education. The increased cost of the exchequer of the education grant will be £2,750,000, but this year the grant will be confined to the necessitous school areas. The government is to contribute one half of the cost of the feeding of hungry school children, and also to make grants for physical training, open-air schools, maternity centers and technical, secondary and higher education. Referring to these grants, Mr. Lloyd George said: "The grants for technical, secondary and higher education are to make it more accessible to the masses of the children, and to extend its sphere of influence where children show any aptitude to take advantage of it. We compare very unfavorably with Germany and the United States of America in this respect.

There there is adequate provision for technical training, secondary and higher training for every child who shows any special gift for taking advantage of it, and I consider that this fact is a greater menace to our trade than any arrangements of tariffs."

At Cornell University Assistant Professors O. A. Johnson and M. F. Barrus have been promoted to full professorships in the department of entomology and the extension department of plant pathology, respectively.

At Hamilton College Professor Nelson Clark Dale, assistant professor of geology at Princeton University, will succeed Professor W. J. Miller, who goes to Smith College.

Mr. C. G. DARWIN, eldest son of the late Sir George Darwin, has been appointed mathematical lecturer at Christ's College, Cambridge.

DISCUSSION AND CORRESPONDENCE

TWO UNDESCRIBED SPECIMENS OF *CASTOROIDES OHIOENSIS* FOSTER FROM MICHIGAN

THERE are two specimens of *Castoroides ohioensis* in the collection of the museum of geology, University of Michigan, that were found in the state and have not been recorded. One of these was discovered near Owosso, Shiawassee County, in December, 1892, by A. G. Williams. It is represented by the base and upper part of the right mandible with the incisor and all of the molar teeth in position, the base of the left mandible, and the left incisor tooth. The incisors are well preserved and show the longitudinal striæ and cutting edge, but the tip and base of each are broken. The row of molar teeth is 75 mm. long.

The second specimen, a skull without the mandibular bones, was exhumed in a tamarack swamp in Pittsfield township, Washtenaw county, by J. B. Steere, in 1902. It was lying on a bed of gravelly marl and beneath three feet of peaty soil. The skull is hard, of a rich dark brown color, and is little damaged. The left zygomatic arch is broken, and the teeth, with the exception of the last molar on the left

side and the right incisor tooth, are missing. Nearly the full length of the right incisor is represented, the only damage to the tooth being an injury to the outer surface and the loss of a few millimeters from the base. The double nature of the internal nasal orifices is well shown. The measurements are as follows:

	Mm.
Length of skull from occipital angle to forward end of nasals	280
Length of skull from occipital angle to forward end of maxillaries	293
Width of skull across occiput	168
Width of skull across zygomatic arches	230
Height of skull at occiput	68
Height of skull at last molars	98
Length of nasals	116
Greatest dimensions of zygomatic arch..	67 × 115
Width of occipital foramen	36
Length of molar tooth row	73

The writer is indebted to Professor E. C. Case, of the department of geology, University of Michigan, for permission to publish these records.

NORMAN A. WOOD

MUSEUM OF ZOOLOGY,
UNIVERSITY OF MICHIGAN

SCIENTIFIC BOOKS

Outlines of Chordate Development. By WM. E. KELLICOTT. New York: Henry Holt & Co. 1913.

In this volume Professor Kellicott endeavors to give a compact though comprehensive account of the development of the Chordates, such as will be suitable for the student of general embryology. For this purpose the frog is taken as representing the type, or rather, one should say, the mean, of chordate development, and a full and connected account is given of its early development and organogeny. This account is, however, preceded by an excellent statement of the embryology of *Amphioxus*, the author believing that whether or not this represents a truly primitive type of development, "it affords, in simple diagrammatic style, the essentials of early Chordate development," while its specialized later stages "may serve to put the student upon his guard

against a too exact phylogenetic interpretation of embryological facts." While admitting the correctness of the first of these statements, from the point of view of the student seeking an outline of the principles of Chordate development one may question the pedagogical propriety of adding a number of more or less irrelevant facts for the purpose of enforcing a conclusion which may be deduced with even greater clearness from the more pertinent embryological phenomena of the higher chordates.

Following the account of the frog, the early development and organogeny of the chick is considered, and the book ends with a chapter on the early development of the mammalia, special attention being devoted to the development of their embryonic membranes and to that of the external form of the human fetus. It is unfortunate for the continuity of the descriptions that no mention is made of the early processes of development of the Reptilia, since these in several particulars afford a much clearer transition to the specialized mammalian conditions than do the similar stages of the chick. The account of the later stages of *Amphioxus* might well have been replaced by a description of the early stages of reptilian development.

But, on the whole, Professor Kellicott's book is an excellent one, both in its conception and execution. The descriptions are clear and without redundancy and are illustrated by numerous well chosen illustrations. Extensive bibliographic lists are appended to the various sections and there is an excellent index.

J. P. McM.

Chemical Technology and Analysis of Oils, Fats and Waxes. By Dr. J. LEWKOWITSCH. In three volumes. 5th edition. Volume I. Macmillan Company. 1913. \$6.50.

This volume has increased from 542 to 668 pages: the chapters on the Constituents and on the Examination of the Mixed Fatty Acids being increased by nearly one third. In view of the encyclopedic character of the book, one is surprised to find no mention of the absolute viscosimeter; of Dunlap's excellent

method of purifying alcohol for alcoholic potash; of T. W. Richards' apparatus for distilling in vacuo by electricity, all of which are admirably adapted for work with fats and oils. The information regarding the Saybolt viscosimeter, too, is not the latest, although perhaps the latest published.

The reviewer regards the treatment of the subjects as most thorough and eminently satisfactory. It is wisely critical, showing evidence of investigation done under the doctor's own eyes. It is approached by nothing in any language, as is attested by the fact of its translation into French and rewriting in German. It is invaluable to every one having to do with fats, oils and waxes.

It will be noted with deep regret by all in this branch that the appearance of the book in this country closely coincided with the death of its author.

A. H. GILL

SCIENTIFIC JOURNALS AND ARTICLES

THE April number (Vol. 15, No. 2) of the *Transactions of the American Mathematical Society* contains the following papers:

Maurice Fréchet: "Sur la notion de différentielle d'une fonction de ligne."

J. H. M. Wedderburn: "A type of primitive algebra."

C. T. Sullivan: "Properties of surfaces whose asymptotic curves belong to linear complexes."

E. W. Chittenden: "Relatively uniform convergence of sequences of functions."

H. S. Vandiver: "Note on Fermat's last theorem."

E. R. Hedrick and Louis Ingold: "A set of axioms for line geometry."

G. C. Evans: "The Cauchy problem for integro-differential equations."

THE March number (Vol. 20, No. 6) of the *Bulletin of the American Mathematical Society* contains: Report of the twentieth annual meeting of the society, by F. N. Cole; Report of the winter meeting of the society at Chicago, by H. E. Slaughter; "Shorter Notices"; Zorretti's *Leçons sur le Prolongement analytique* and Scheffers's *Serret's Lehrbuch der Differential- und Integralrechnung*, by Frank

Irwin; Meyer's Theorie benachbarter Geraden und ein verallgemeinerter Krümmungsbegriff, by E. B. Cowley; Hilbert's Grundlagen der Geometrie and Grundzüge einer allgemeinen Theorie der linearen Integralgleichungen, by T. H. Gronwall; Lebon's Gabriel Lippmann, Moritz's College Mathematics Notebook and College Engineering Notebook, and Harris's Gravitation, by E. B. Wilson; "Notes"; and "New Publications."

THE April number of the *Bulletin* contains: "An unpublished theorem of Kronecker respecting numerical equations," presidential address, by H. B. Fine; "Two convergency proofs," by Arnold Emch; "Some properties of the group of isomorphisms of an abelian group," by G. A. Miller; Review of Landau's Handbuch der Lehre von der Verteilung der Primzahlen, by T. H. Gronwall; Review of Fisher's Purchasing Power of Money, by E. B. Wilson; "Shorter Notices"; Clebsch-Lindemann's Geometrie, by Joseph Lipka; Weyl's Die Idee der Riemannschen Fläche, by F. R. Moulton; "Notes"; and "New Publications."

THE May number of the *Bulletin* contains: Report of the February meeting of the society, by F. N. Cole; "A non-enumerable well-ordered set," by A. B. Frizell; "Note on the Fredholm determinant," by W. A. Hurwitz; "Time as a fourth dimension," by R. C. Archibald; Review of Bützberger's Bizentrische Polygone, Steinersche Kreis- und Kugelreihen und die Erfindung der Inversion, by Arnold Emch; "Shorter Notices"; Loria's Poliedri, Curve e Superficie secondo i Metodi della Geometria descrittiva and Darstellende Geometrie, zweiter Teil, by Virgil Snyder; Czuber's Differential- und Integralrechnung, by L. W. Dowling; Ciani's Lezioni di Geometria proiettiva ed analitica, by E. B. Cowley; Hessenberg's Transcendenz von e und π and Bolza's Variationsrechnung, by T. H. Gronwall; Picard's Das Wissen der Gegenwart in Mathematik und Naturwissenschaft, by J. B. Shaw; Sturm's Maxima und Minima in der elementaren Geometrie, by J. V. McKelvey; Norris and Craig's Advanced Shop Mathematics, by P. F. Smith; Czuber's Wahrschein-

lichkeitsrechnung, by H. B. Phillips; Lord Kelvin's Mathematical and Physical Papers, volumes IV., V. and VI., and Love's Problems of Geodynamics, by E. B. Wilson; Annuaire pour l'An 1914 publié par le Bureau des Longitudes, Combebiac's Les Actions à Distance and Abbe's Mechanics of the Earth's Atmosphere, by E. W. Brown; "Notes"; and "New Publications."

SPECIAL ARTICLES

THE SYSTEMATIC POSITION OF THE MYLODONT SLOTHS FROM RANCHO LA BREA¹

IN the excavation work carried on by the University of California in the Pleistocene of Rancho La Brea, a considerable percentage of the material obtained represents ground-sloths of the mylodont group. Twenty-seven skulls, representing the family Mylodontidae, are now in the collection of the department of paleontology. Of these, nineteen are well preserved and show the dental series on both sides. Many lower jaws are also available, several of which are associated with the skulls. In a preliminary consideration of this extensive series of specimens, certain suggestions as to the relationship of some of the mylodont genera have presented themselves. It seems desirable, therefore, to make this information available for other students of the group.

The writer is indebted to Professor John C. Merriam for kind assistance during this study.

The genera *Mylogodon* and *Paramylodon*, to which the Rancho La Brea material has previously been referred, are the members of the family Mylodontidae definitely recognized in the North American Pleistocene. A fragmentary lower jaw, originally described by Harlan from Big Bone Lick, Kentucky, was referred to *Mylogodon* by Owen in 1840. In 1903 Brown² established the genus *Paramylodon* on a skull and lower jaw with associated skeletal material obtained from Pleistocene deposits near Hay Springs, Nebraska.

¹ Read at the fifth annual meeting of the Paleontological Society, Princeton, N. J., January 1, 1914.

² Brown, B., *Bull. Amer. Mus. Nat. Hist.*, Vol. XIX., Art. XXII., pp. 569-583, 1903.

In 1909 Cockerell³ briefly described a skull from Walsenburg, Colorado. Brown believed it to be distinct from *Paramylodon* and assigned it to the genus *Mylodon*. Some doubt as to the validity of the genus *Paramylodon* was subsequently expressed by Osborn,⁴ though Allen,⁵ in a recent paper, accepts the determination of Brown.

The diagnostic characters of the genus *Paramylodon* were stated by Brown as follows:

Skull elongate; muzzle inflated; dentition $\frac{4}{3}$; first upper molar the largest of the series; last lower molar trilobate; first lower molar without opposing tooth.

The nineteen skulls from Rancho La Brea are similar to the Nebraska and Colorado specimens in the elongation of the head and the inflation of the muzzle. In several of the California specimens the teeth have fallen from the sockets, the study in such cases being restricted to the alveolar outlines. The series arranges itself as follows:

1. Four skulls with four teeth on both sides.

2. Six skulls with four teeth on one side and five teeth on the opposite side.

3. Nine skulls with five teeth on both sides.

The superior dentition varies, therefore, from four to five teeth on each side; and this variation appears to be independent of the age of the individual. It follows from the variable presence of the first tooth, that it is the second superior tooth which is the largest of the series. Upon the presence of the first superior tooth depends, also, the nature of occlusion with the first inferior tooth.

The fourth inferior tooth, in a series of five lower jaws, is most distinctly trilobed in an individual of the first group. The tooth appears slightly less trilobed in individuals of the second and third groups, and may be two-lobed in the last group.

Judging from the variation in the large

series from Rancho La Brea, the form described by Brown, as well as the remains from the asphalt deposits, should apparently be placed in the genus *Mylodon*. The earlier authors would probably have arrived at a similar conclusion, had this extensive collection been available. Allen considers the Colorado skull as belonging to *Mylodon harlani* Owen. Possibly the specimens from Nebraska and Colorado are closely related specifically to the Rancho La Brea remains. At present the writer will only state that the inferior dental series of several mandibles from Rancho La Brea bear a close resemblance to the type specimen of *M. harlani*.

A third type of ground-sloth from North America, which has been considered with the *Mylodontidae*, is the genus *Morotherium* described by Marsh⁶ in 1874 from remains found in Alameda county, California. Marsh considered *Morotherium* closely related to *Mylodon* and *Megalonyx*. It was distinguished from *Mylodon* by the absence of the depression in the head of the femur for the ligamentum teres. The humerus of *Morotherium* differed from *Megalonyx* in the absence of the supracondylar foramen. In 1899 Merriam⁷ described a humerus from Pleistocene strata near Tomales Bay, California. It resembled closely the known portion of Marsh's specimen and was referred to *Morotherium*, although the validity of the genus was questioned by the writer.

A comparison of the Tomales Bay humerus with several specimens from Rancho La Brea indicates that the former specimen undoubtedly belongs to *Mylodon*. The writer has not seen the type (femur) of *Morotherium*. As stated by Marsh, it resembles *Megalonyx* in general shape. The specimen, as figured, appears to be quite different in shape from the *Mylodon* femurs of the asphalt deposits. The absence of the notch for the ligamentum teres can hardly be considered as generically distinctive of *Morotherium*, as it may be absent

Soil Bacteriology

Bacterial Activities and Crop Production: P. E. BROWN.

The importance of correlating the results of bacteriological tests with known facts regarding soil fertility is emphasized. The improvements in methods for the bacterial examination of soils has made possible the study of the relation between bacterial activities and crops produced. Thus the determination of the ammonifying power, the nitrifying power or the azoifying power of soils may be an indication of their fertility or crop-producing power, or at least of the relative fertility of several soils.

Soils under varying rotations and under different treatment have been studied during the past three years, and the results secured show in practically every case a similar, definite relation between the crops produced on the various plots and the ammonifying power and the nitrifying power of the soils determined by the fresh soil-casein method for the one and the fresh soil-ammonium sulfate method for the other.

It is evident that the bacterial activities in soils determine very largely the crop-producing power of the soils. If the bacterial mechanism which brings about the solution of insoluble plant food is inadequate, crops will suffer for lack of food. In soils where improper rotations and poor treatment is practised the conditions very quickly become unsatisfactory for optimum bacterial growth and crops immediately feel the effect of this diminished growth in a reduced supply of food. The work, as a whole, therefore, points toward the value of bacterial tests as a measure of the crop-producing power of soils.

The Environment of Soil Organisms: F. H. HESSELINK VAN SUCHTELEN.

¹ Abstract of papers presented.

Growing out of the importance of the action of media on organisms a study of soil as a cultural medium was undertaken. So far as our present knowledge concerning soils extends, the only means at our disposal for judging the cultural medium of soil organisms is drainage water. It may be expected, however, that the soil solution as it exists in the soil differs quantitatively from the drainage water.

A method was devised for obtaining this soil solution based on its displacement by inactive substances (paraffine oil, vaseline, etc.). Work by means of the determination of osmotic pressure and electrical conductivity was undertaken, which demonstrated the value of such a displacement.

The absolute amount of soil solution obtained by the above-mentioned method varied from 100-435 c.c. solution. As an example of the successful extraction the following data may be quoted. From 7.949 kilograms of sandy loam with a total water capacity of 24.6 per cent. containing 14.3 per cent. water (all figured on the basis of dry soil), there was obtained 330 c.c. of soil solution. The concentration of the soil solution bears a resemblance to the very first portion of drainage water obtained by careful percolation through a large quantity of soil.

Besides an extensive study of the soils employed in our experiments, there were made physico-chemical and chemical examinations of the liquid obtained by the foregoing displacement process, together with a determination of the number of microorganisms found by the plate method. It was ascertained that different soils, soils closely adjacent and the soils of different layers, contained soil solutions of different compositions. Detailed results will appear in a future publication.

A New Medium for the Quantitative Determination of Bacteria in Soil: H. JOEL CONN.

Three special media for soil work have been proposed during the last few years: by Hugo Fischer,² by J. G. Lipman³ and by P. E. Brown.⁴ Recently an asparaginate agar containing wholly chemicals of known composition has been prepared at the New York Experiment Station. A fifth medium, a soil-extract gelatin, has been compared with them, because it has been found to give a very high and regular count. The composition of these media are as follows:

² *Centbl. f. Bakt.*, II., Ab. 25, p. 457.

³ *Id.*, 25, p. 447.

⁴ *Id.*, 38, p. 497.

	Asparag. Agar	Fischer's	Lipman's	Brown's	Soil-Extr. Gelatin
Water.....	1,000	—	1,000	1,000	900
Soil-extract.....	—	1,000	—	—	100
Agar.....	12	12	20	15	—
Gelatin.....	—	—	—	—	120
Peptone.....	—	—	.05	—	—
Albumin.....	—	—	—	.1	—
Na. Asparag.....	1	—	—	—	—
Dextrose.....	1	—	10	10	1
MgSO ₄2	—	.2	.2	—
K ₂ HPO ₄	—	2	.5	.5	—
NH ₄ H ₂ PO ₄	1.5	—	—	—	—
KCl.....	.1	—	—	—	—
CaCl ₂1	—	—	—	—
FeCl ₃	Trace	—	—	—	—
Fe ₂ (SO ₄) ₃	—	—	—	Trace	—

In the asparaginate agar the reaction should be carefully adjusted to 0.8 per cent. normal acid to phenolphthalein. The dextrose and asparaginate should be added just before tubing.

Some thirty-five comparative tests of the gelatin with one or more of the other media have been made. Various soils have been used for inoculating. Incubation has been at 180° C. for seven days with gelatin and fourteen with agar, which allows a very high count (5-50 million in normal field soil). The following figures (referred to in terms of colonies on asparaginate agar as 100) represent instances that seem to be typical:

	Asparag. Agar	Fischer's	Lipman's	Brown's	Soil-Extr. Gelatin
Case 1	100	170	68	57	113
Case 2	100	85	75	Irregular	93

About forty other tests have been made to determine the best proportions of the various constituents in the asparaginate agar. None have proved more satisfactory than the above formula.

As a result of this work the asparaginate agar is highly recommended. The only medium which seems better, either in respect to count or to the colony differentiation, is soil-extract gelatin; and because of the addition of soil extract this gelatin is not one that can be readily duplicated. The only one of the media investigated which gives a higher count than either of these is Fischer's soil-extract agar, which does not allow good colony differentiation. The detailed results of this work are to be published as a technical bulletin of the New York Agricultural Experiment Station.

Antagonism Between Salts as Affecting Soil Bacteria: CHAS. B. LIPMAN.

With Loeb's conception of physiologically balanced solutions as a basis, the author has carried on experiments dealing with a phase of the subject hitherto regarded as of little significance, namely, the antagonism between anions. The most striking results have been obtained with such antagonism between anions through the use of the so-called alkali salts which commonly include sodium chloride, sodium carbonate and sodium sulfate.

Results of antagonism between the anions of these salts show that both as regards ammonification and nitrification, it was possible to improve the soil as a medium after it had been made toxic for the bacteria in question, by means of any one of these salts, through the addition of any other of the three salts mentioned. Thus briefly, it was possible at times to triple and quadruple the total salt content of the soil and still make it a better medium for ammonification and nitrification than it was with one third or one fourth of the total salt content consisting, however, of but one salt. The author claims for this great significance in the direction of the management and control of alkali land.

Sulfocation in Soils: P. E. BROWN AND E. H. KELLOGG.

Recent work has shown that considerably larger amounts of the element sulfur are removed from soils by the growth of crops than has been supposed. The inaccuracy of the old method used in the determination of the sulfur in crops explains the discrepancy. Soils have been shown to contain in most cases only a limited supply of sulfur, usually a smaller amount than of phosphorus. The problem of the sulfur feeding of plants is therefore coming to be of considerably more importance than it has been in the past. The natural means of returning sulfur to the soil is by the use of farmyard manure or green manure and in these materials it is added in a complex organic form in the proteins. The sulfur in these must be transformed into sulfates to be of use to plants.

Here is where the sulfifying bacteria appear. They are the agents which bring about the change of organic sulfur into sulfates. Many questions immediately arise in a consideration of this point. Do soils have a sulfifying power? Can this be determined? How? What is the relation of the sulfifying power of soils to the sulfur feeding of plants? etc. This work deals with the first question and shows that soils do have a definite sulfo-

fyng power which varies with the type of soil, soil treatment, etc.

The sulfofying power of soils may be determined in the laboratory in the following way:

100 grams of fresh soil obtained with all precautions that it shall be representative and uncontaminated are weighed out in tumblers and thoroughly stirred. Then 0.1 gm. of a sulfide (Na_2S) or sulfur is added. Moisture conditions are brought up to the optimum by additions of sterile water. The soils are incubated for 4-5 days at room temperature. At the end of that time the sulfates are leached out by shaking for six hours with water in a shaking machine. The sulfate content of the soil itself is determined and the purely chemical oxidation of the sulfide occurring upon shaking the sulfide for six hours with the soil is also ascertained.

The sum of these two is subtracted from the total sulfate content of the soil after incubation and the difference gives the sulfofying power of the soil, or the physiological efficiency of the sulfoxidizing bacteria in the soil. Many difficulties have been met in the work and largely overcome. Details regarding these will appear in a future publication. The point to be emphasized by the results so far is that soils have a definite sulfofying power which is determinable in the laboratory and therefore the efficiency of fertilization of soils with organic sulfur compounds may be ascertained for any soil.

Further Studies with Some Azotobacter: DAN H. JONES.

Viability of Azotobacter in Stock Cultures.—Equal quantities of azotobacter growth were taken from cultures grown on Ashby's agar for varying periods of time and plated out in beef gelatin. The relative colony counts were as follows:

Culture 16 days old	9,000 colonies
Culture 2 months old	8,000 colonies
Culture 5 months old	5,000 colonies
Culture 7 months old	4,500 colonies
Culture 1 year and 4 months old...	2,200 colonies
Culture 2 years and 2 months old ..	60 colonies

This work was duplicated with the four varieties of azotobacter under observation with approximately same results.

Thermal Death Point of Azotobacter in Stock Cultures of Different Ages.—The cultures used for the viability test were tested for their thermal death point, by mixing one loopful of culture in 10 c.c. of Ashby's solution and then held in water bath for 10 minutes at the required temperature.

All cultures heated up to 55° C. gave good growth.

All cultures heated up to 65° C. and over gave no growth.

Involution Forms.—Involution forms of azotobacter varying very much in shape and size may appear in cultures grown in Ashby's solution and Ashby's agar at any temperature within growth limits. This tendency to produce involution forms is comparatively slight at 20°-25° C., but excessive at 37° C. Involution forms taken from an Ashby agar culture 2 months old were tested for their power to reproduce in Ashby's agar in moist chambers. Fifteen were held under observation for four days, but during that time only one reproduced. Normal cells present in the same fields produced colonies which overgrew the involution forms.

Azotobacter and Plant Growth.—It was decided to test the power of azotobacter to fix sufficient atmospheric nitrogen for plant growth. Special vessels were designed for the purpose. These were filled with well-washed quartz sand, sterilized, soaked with Ashby's solution and inoculated with azotobacter, controls being kept. After two weeks, grains of wheat were sown in the pots of sand. These all germinated and gave growth-producing plants 16 inches high in one month, but no difference was observed at this time between the culture plants and the controls.

A Possible Improvement in the Technique of Determination of the Ammonifying Power of Soils: T. D. BECKWITH AND A. F. VASS.

One of the difficulties met with in determining the ammonifying power of soils is that part of the ammonia was lost under the older methods. We have found it possible to determine the total amount of ammonia given off by soils by a very simple method of laboratory technique. The soil, generally 100 or 200 grams in content, is placed in a 1,000 c.c. Erlenmeyer flask. In the top of the flask is inserted a two-hole rubber stopper. The air is allowed to enter the flask through the inverted U-tube. The outer tube is made of a simple elbow placed in the other hole of the stopper. This flask thus prepared is connected with a water pressure filter pump. In the series between the soil flask and the pump is placed a wash bottle containing $\text{N}/10 \text{ H}_2\text{SO}_4$. For purposes of an indicator this acid solution is colored slightly with cochineal. When soil and the material to be ammonified is placed in the soil flask, air is drawn through the system by the filter pump. The ammonia is intercepted by the acid. The indicator in the wash bottle shows the point of neutralization.

When neutralized another wash bottle with an aliquot portion of acid is substituted. A final determination of the amount of ammonia in the soil flask plus that of the acid in the wash bottle shows the exact amount of ammonia given off. A large series of flasks and wash bottles may be served by the same filter pump, using appropriate connections of Y and T tubes with heavy-walled rubber tubing. It is necessary to use screw pinch cocks throughout the system in order to regulate the flow of air through the wash bottles and to see that none are cut off. Such a system should be used and adjusted for at least twenty-four hours before the soil and material to be ammonified are added in order to make sure that all is in perfect working condition.

A Bacterial Disease of the Larvæ of the June Beetle, Lachnosterna Spp.: ZAE NORTHERP.

During the summer of 1912, the larvæ of the June beetle, *Lachnosterna* spp. committed serious depredations to crops. Specimens sent in to the entomological department by the farmers were found to be diseased and were turned over to the bacteriological laboratory for the determination of the etiology of the infection, and, if practicable, to use the living parasite as a remedial measure.

This disease which is characterized by a blackening of the affected parts, was found to be due to a micrococcus, which was found microscopically in smears and in sections from diseased tissue. This organism was isolated from the affected tissues of a living grub and liquid cultures were used for the inoculation of the soil in which healthy larvæ were then placed. Oftentimes infection occurred within a short time; the most marked infection occurred when an incision was made in the integument, a characteristic lesion developing within twenty-four hours. It was discovered that an excessive amount of water in such inoculated soil favored the rapid progress of the disease. This seems to be one of the most important factors in determining the fatality of the infection. This disease may be transmitted characteristically to larvæ of the southern United States June beetle, *Allorhina nitida* and to the American cockroach, *Periplaneta americana*, but is non-pathogenic to rabbits or guinea-pigs. The black pigment characterizing the disease is probably produced directly or indirectly by the activity of the bacterial cells within the larval tissues; the cocci and the integument cells in which they are imbedded do not take the ordinary or the Gram stain but remain dark brown in color. From the characteristic lesions produced by this organism it has been

named "*Micrococcus nigrofaciens*." No results have as yet been obtained in trying out this organism as a remedial measure for the destruction of the white grub. Cultures of the micrococcus have been sent to Porto Rico for this purpose.

Sanitary Bacteriology

A Numerical Comparison of the Organisms Producing Gas in Lactose Bile Isolated from the Baltimore City Water Supplies: J. BOSLEY THOMAS AND EDGAR A. SANDMAN.

The water supply of Baltimore city is derived from two streams which flow through a rather populous rural district. The larger stream, which has an average daily flow of about one hundred million gallons, drains a watershed supporting many large dairy farms, while the other, with a flow of twenty million gallons per day, is derived from a watershed supporting fewer dairy farms in proportion to its area, but known to be subject to a greater extent to possible sewage pollution. It, therefore, occurred to us that there might be shown in one of these supplies the presence of a different relative proportion of certain types of organisms than in the other supply; and a pollution derived largely from dairy-farms and creameries is obviously of a less serious character than a pollution caused principally by the introduction of sewage. For the classification of these organisms four sugars, in addition to the customary use of gelatin, were used, viz.: lactose, dulcitol, saccharose and dextrose. Endo's agar was used for isolating the organisms in pure culture, and the results of a study of the character of colonies formed on this medium is given in the original paper. The average number per c.c. of the several types of organisms was estimated by considering the number of positive and negative tests in each dilution and following the method described by Phelps before the American Public Health Association in 1907. The results of this work, embracing 383 isolations from untreated water, show an average number of 2.79 organisms per c.c. giving cultural characteristics of *B. coli communis* and *B. coli communior*, and 9.31 organisms per c.c. giving cultural characteristics of *B. (lactis) aerogenes* and *B. acidilactici*, in the Gunpowder River, which is exposed to pollution from dairy-farms, in comparison with 5.12 organisms of the former types and 4.98 of the latter types in the Jones Fall supply, which is more exposed to sew-

age pollution. It is, therefore, seen that although the total number of these organisms is about the same in either supply, there are nearly twice as many *B. coli*-like organisms in the supply subject to greater sewage pollution than in the Gunpowder River.

Notes on the Bacteriology of Air and Its Sanitary Significance: C. E. A. WINSLOW.

Both mouth spray and dust contain buccal bacteria and at times pathogenic forms, and might theoretically constitute sources of appreciable atmospheric pollution. Whether they actually do so or not can only be determined by quantitative studies of the bacteria actually present in air and particularly of the characteristic organisms of the mouth. Two sets of results bearing upon this point are here reported.

A series of 684 examinations of school room air in New York City made by Professor Chas. Baskerville and the writer gave an average of 96 microbes per cubic foot. This includes all organisms developing on litmus lactose agar in five days at room temperature. Two hundred and sixty-eight samples gave counts under 50, 178 between 51 and 100, 112 between 101 and 150, 39 between 151 and 200, 23 between 201 and 250, 12 between 251 and 300, and 17 over 300. Lactose fermenting streptococci (characteristic buccal forms) were found 52 times in 174 cubic feet of air giving an average of 30 per 100 cubic feet of air.

The second series of results includes 64 samples of outdoor air (mainly from New York City streets) examined in the course of a somewhat detailed study of air bacteriology now being carried on by the New York State Commission on Ventilation. The average 20° count of 64 samples was 59 microbes per cubic foot. Twenty-four samples showed less than 25, 18 between 26 and 50, 8 between 51 and 100 and 14 over 100. The maximum count was 395. At 37° in two days the average count was 48 microbes per cubic foot. Thirty-six samples were below 25, 9 between 26 and 50, 9 between 51 and 100 and 7 over 100. Acid forming streptococci were absent from 12 cubic feet of air examined for their presence.

The Usefulness of Dried Stained Smears of Milk as a Means of Determining the Sanitary Quality of Milk: ROBERT S. BREED AND JAMES D. BREW.

A number of tests of the method of making milk smears devised by Prescott and Breed⁴ have

been made at the Geneva Experiment Station with a view of determining the sanitary quality of milk. It has been found to be a very rapid and efficient method of determining the total germ content where milk contains 100,000 or more bacteria per c.c. The results secured probably represent the real conditions so far as total content is concerned better than those secured on agar or gelatin plates. By means of this test it is possible to separate milk as received at a milk station into two classes by a rapid examination of the prepared smears. The first grade of milk is that in which no bacteria are seen in 5 to 10 or more fields of the microscope. In all but eight of the sixty samples in which no bacteria were found the agar plate count was less than 100,000 per c.c. and seven of the eight which exceeded this figure were less than 200,000 per c.c. Such milk would sell in the New York City market as Grade A, selected pasteurized if properly pasteurized. Inasmuch as a large proportion of the milk received at the particular milk station where the tests were made was of this quality this test would have been used to great advantage because it would have enabled the dealer to raise this part of his milk from Grade B to the Grade A class at no expense to himself or to the farmers supplying the milk except the cost of making the tests, which is fortunately not great enough to be prohibitive.

The second class of milk would be that in which bacteria are readily found with the microscope. Such milk under present regulations would go on the market as Grade B milk if properly pasteurized. The great advantage of this test over plate methods of examinations or other bacterial methods that require an incubation period, is that results can be secured in a very few minutes and a large number of samples can be handled by a single person. Any person sufficiently skilled to handle a microscope can learn the technique and apply the method successfully. The chief weakness of the method at present is that it is so new and has been tried out so little in a practical way that no one knows as yet how the results secured should be interpreted. The bacterial counts obtained are much higher than those obtained from the ordinary plate counts and there is no constant relationship between such counts where single comparisons are made. When a long series of comparisons are made between plate counts and these microscopic counts, it is found that greater discrepancies occur when the total number of bacteria is low than when the total number of bacteria is high. A detailed report on this work will

⁴ *Journal of Infectious Diseases*, 7, p. 632, 1910.

be published in a technical bulletin of the New York Experiment Station.

Field Organization and Laboratory Technique, Canadian Section—International Joint Commission Pollution Investigation, 1913: F. A. DALLYN.

Period of investigation—April 10 to October 10, 1913.

Field laboratory located at nine (9) bases, from Fort Frances, Ont., to Kingston, Ont.

Equipment at each base comprised:

- 2 incubators — 18° C., — 22° C. and 37° C., designed to hold maximum number of samples.
- 2 sterilizers, one for glassware and the No. 3 Bramhall Deane Autoclave.
- 400–500 petri dishes with copper cases, 4 copper 25 c.c. pipette cases containing 30 pipettes each, 3 copper 1 c.c. pipette cases containing 60 pipettes each, 300–400 6-oz. glass stoppered sample collection bottles.

Apparatus for obtaining deep samples. Several hundred Dumas bulbs, necessary table apparatus and media-making equipment.

Twelve thousand eight hundred (12,800) samples were collected and examined. The determination of the total bacteria count on nutrient agar (+10) at 18°–22° C. (48 hours), the count at 37° C. (24 hours), and the quantitative estimation of *B. coli* as indicated by fermentation in lactose bile at 37° C. (48 hours), not less than four (4) dilutions used for the latter—usually 1, 5, 25, 50 c.c. were tubed (1/1000, 1/100, 1/10) only when required. Sample collection points were located on straight lines by a time interval method (checked by different landmarks, buoys and light-houses). Stoppers and necks of sample bottles protected from contamination by a rubber dam held by a band. The dam was dipped in mercuric chloride solution before being re-used.

Each field laboratory examined on an average of 52 samples per day. Max. amount 103 samples per day for 3 days in succession. Ten (10) to twenty (20) daily samples taken at each sample collection point. Special paragraphs on tabulation, accounting system, plating and tubing technique, handling of media, media reaction and washing of glassware.

The Virulence of the Resistant Minority: FRANK SCHOFIELD.

The work described has been done in an endeavor to obtain facts which would give a satisfactory basis for answering the following questions: Considering bacteria of the same species, have those which exhibit the greatest resistance to germicidal action a corresponding increase of pathogenic power over their fellows which succumb?

Or, are the few which survive exposure for long periods to detrimental conditions practically innocuous?

In the experiments done swabs were inoculated from pure culture of *B. Diphtheria* and placed in the sunlight and others in the dark. At the same time definite quantities of special broth were inoculated, incubated for two days and varying amounts injected into guinea-pigs of known weight. Cultures were made from the inoculated swabs at different periods such as 30 days and number of colonies developing noted, for instance 100, then again at 35 days when number of colonies might be 50. By careful manipulation the time when but two or three organisms capable of growing on the culture media were left could be estimated. Such colonies would represent the most resistant of the strain used. From such colonies broth was inoculated and incubated under similar conditions, as at the beginning of experiment. Guinea-pig inoculation was made and results compared with results recorded at commencement of experiment. A series of eleven experiments such as these were undertaken and the results warranted the following conclusion: That cultures made from the most resistant individuals of a strain usually exhibited pathogenic properties similar to the less resistant organisms of same strain, the virulence neither being increased nor decreased materially.

The Influence of the Hypochlorite Treatment of Water upon the Development of Algæ: CARRIE M. DERICK.

Professor Derick briefly reported some general observations incidentally made by a graduate student, Miss Clare Miller (Mrs. Wasteney), in the course of a study of the Algal Flora of the Island of Montreal, in 1911 and 1912. Collections of algae made in October and November, 1911, were maintained in sixty or more aquaria in the botanical laboratories of McGill University. In addition to series in various media, parallel cultures were grown in ordinary tap water. At that time, the city water was being regularly treated with hypochlorite of lime, less than one part to a million parts of water being used. The development of deleterious bacteria being thus prevented, the cultures of algæ in this water, which contained all the necessary mineral nutrients, were unusually vigorous and long-lived. At temperatures about 20° C., blue-green algæ, especially *Oscillatoria tenuis* Ag., *O. splendida* Grev. and *Rivularia hamatites* Ag., flourished. *Anabaena*, on the contrary, usually died or passed into a resting condi-

tion within a few days. In March, however, it reappeared and grew well. Desmids, such as *Cozmium*, *Closterium* and *Micrasterias*, as well as *Mougeotia*, *Ulothrix* and *Stigeolium*, which were collected in the spore stage, germinated and grew readily at a temperature of 20° C. *Spirogyra*, *Vaucheria* and *Cladophora* were most successfully grown at a temperature of 5° C. or less. The majority of the Chlorophyceæ collected grew vigorously in city water, provided that the temperature was between 5° C. and 20° C. *Vaucheria*, *Scenodermus* and other Protococceæ flourished throughout the year. *Edogonium* and *Chato-phora* developed freely towards spring. Diatoms, such as *Navicula*, were plentiful at low temperatures. By periodically renewing the water to prevent the concentration of the mineral contents and by guarding against excessive exposure to strong light, many aquaria were kept in good condition during the following summer and supplied much material used for class-work throughout the winter of 1912-13. Towards spring, in 1913, *Scenodermus* and a few other types crowded out less resistant groups, and the cultures were allowed to die during the summer of 1913.

Algae similarly treated in the autumn of 1913 have not developed well. The summer was unfavorable to the majority and they were not in good condition when collected. *Spirogyra* and other Conjugatæ, several of the Protococceæ and *Edogonium* began to grow after a few weeks. But in December, practically all of the aquaria contained species of *Bacillus*, *Spirillum* and *Vibrio*, as well as one or two water molds. Several factors probably contributed to this result. A less rigorous use of hypochlorite of lime in the treatment of the city water was suggested as a partial explanation by Dr. Adami during the discussion which followed the reading of the paper. It is obvious that when water-supplies are freed from bacteria by means of hypochlorite of lime, such a free development of algae is permitted as to require treatment by copper sulphate or other measures to prevent pollution.

Toxic Products in Food and Their Detection:
CHAS. H. HIGGINS.

Outline of necessity for the formulation of a method which could be used as a standard in routine examinations connected with the administration of the Meat and Canned Foods Act.

Three forms of poisoning in meat food products recorded by Edelmann. These are: (1) poisoning resulting from an infection by the *Bacillus enteritidis* (Gärtner); (2) poisoning resulting

from the toxic products of the *Bacterium coli*, *proteus* species, etc., (3) poisoning resulting from the *Bacillus botulinus*. These food poisonings are the result of a direct bacterial infection or the poisoning from toxic products formed during their growth. Methods of detection are bacterial, such as Rosenau's, the *boiling test*, judgment depending upon the odor and the various feeding tests, principally with mice. None of these meet the requirements of routine examinations, as the individual element is an important factor and one that can not be standardized. The method employed is through the preparation of a solution of the material under consideration; in the case of commercial gelatines a ten per cent. solution, and following the method of Rosenau injecting this subcutaneously in amounts of 1 c.c. to 10 c.c., which contain from 0.1 to 1.0 of the original gelatine. For other meat food products the method is similar save that the food is leached with normal saline or distilled water, either proving equally satisfactory. In every case ten guinea-pigs are used, preferably of 250 grams weight, these having been shown to be most suitable for this purpose.

This method was used on upwards of two hundred samples. In one instance untoward effect occurring in sixteen persons, was directly traced to gelatine entering food product. In other cases untoward effect was found to be due to faulty methods of handling.

Proteid products have not interfered with the results and have not led to uncontrollable factors. Judgment depends upon the presence of illness or death among the inoculated animals. Period of observation, five days.

A. PARKER HITCHENS,
Secretary

(To be continued)

SOCIETIES AND ACADEMIES

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and seventieth regular meeting of the society was held at Columbia University on Saturday, April 25. The attendance at the morning and afternoon sessions included forty-four members. Ex-president Böcher occupied the chair, being relieved by Vice-president Eisenhart, Ex-president Fiske and Professor Tyler. The council announced the election of the following persons to membership in the society: Dr. T. H. Brown, Yale University; Dr. Josephine E. Burns, University of Illinois; Professor C. F. Gummer, Queen's University, Kingston, Ontario; Mr. G.

M. Hayes, College of the City of New York; Dr. W. L. Miser, University of Minnesota; Professor Maximilian Philip, College of the City of New York; Mr. S. A. Schwarz, College of the City of New York; Professor A. G. Smith, State University of Iowa; Mr. W. A. Wetzel, College of the City of New York. Ten applications for membership in the society were received.

Professor L. E. Dickson was reelected a member of the editorial committee of the *Transactions* for a term of three years. It was decided to hold the annual meeting this year in New York.

The society has recently published the Madison Colloquium Lectures, by Professors L. E. Dickson and W. F. Osgood, being volume 4 in the Colloquium Lecture Series.

The following papers were read at this meeting:

A. R. Schweitzer: "An extension of functional equations."

L. P. Eisenhart: "Transformations of conjugate systems with equal point invariants."

H. H. Mitchell: "The subgroups of the quaternary abelian linear group."

R. D. Beetle: "On the complete independence of Schimmack's postulates for the arithmetic mean."

H. S. Vandiver: "Extension of the criteria of Wieferich and Mirimanoff in connection with Fermat's last theorem."

E. G. Bill: "Note on the curvature of a regular curve in non-euclidean space."

S. A. Joffe: "Triangles whose sides are three consecutive integers and whose area is an integer."

G. D. Birkhoff: "The restricted problem of three bodies. Second paper."

A. B. Coble: "Cremona groups determined by point sets."

Anna J. Pell: "Non-homogeneous linear equations in infinitely many unknowns."

Louise D. Cummings: "On a method of comparison for triple systems."

C. L. E. Moore: "A geometry whose element of arc is a linear differential form."

C. L. E. Moore: "On the centers and radii of curvature of curves traced on a surface in an n -space."

J. E. Rowe: "Invariants of the rational plane quintic and of rational curves of odd order."

J. K. Lamond: "Some applications of a theorem of W. H. Young."

Maxime Böcher: "On a small variation which renders a linear differential system incompatible."

R. C. Archibald: "Euclid's book on division of figures."

C. E. Wilder: "On the degree of approximation to discontinuous functions by trigonometric sums."

E. J. Miles: "Transversality and orthogonality of space extremals."

P. R. Rider: "Broken extremals in space."

R. L. Moore: "Linear order in terms of point and limit."

T. H. Gronwall: "Triply orthogonal systems containing one family of minimal surfaces."

The summer meeting of the society will be held at Brown University, on September 8-9.

F. N. COLE,
Secretary

THE PHILOSOPHICAL SOCIETY OF THE UNIVERSITY OF VIRGINIA

At the regular monthly meeting of the Scientific Section of the society on February 16 Dr. W. J. Humphreys, Professor of Meteorological Physics, U. S. Weather Bureau, delivered an address entitled "Volcanic Dust and other Factors of Climatic Control."

On March 23 Professor Graham Edgar presented a joint paper by himself and Mr. S. H. Diggs entitled "The Influence of the Concentration of Potassium Iodide on the Rate of Diffusion of Iodine in Potassium Iodide Solution."

On April 20, 1914, Professor J. S. Grasty presented a paper on "The Shore Lines of the Ore Beds of the Clinton Formation in Alabama."

L. G. HOXTON,
Secretary

THE AMERICAN PHILOSOPHICAL SOCIETY

A PAPER read before the American Philosophical Society on April 3, by Ambrose E. Lehman, "Explorations in the Hudson Bay Region, with Reference to Unusual Topographic and Hydrographic Features and Mineral Deposits," announces the discovery of rich molybdenite ores, at a point immediately south of the new National Transcontinental Railway, in the northern section of the Province of Quebec, 440 miles northwest of Quebec, Indian Peninsula, Keewagama Lake.

Molybdenite crystals and flakes occur in persistent quartz veins traversing the granite and pegmatite rocks of the Laurentian formation.

Exploration and development of the deposits thus far exposes the ore near the surface, in such quantity as to warrant the belief in the magnitude of the find being greater than any heretofore discovered and developed of this rare metal.

New High Vacuum Piston Pump

Made by
E LEYBOLD'S NACHFOLGER

The Gaede High Vacuum Piston Pump, as shown at the recent exhibition of the American Physical Society in Washington, may be easily driven by hand, and requires no auxiliary pump.

It will evacuate a moderate sized X-ray tube from atmospheric pressure until it gives off hard X-rays in less than two minutes, without the use of drying tubes. Accessory apparatus is fitted directly to the standard ground nozzle, thereby avoiding rubber connections.

It will be found useful in lecture rooms, for demonstration purposes, and in experiments requiring high vacua, as a number of striking phenomena, which cannot be obtained in closed tubes, can easily be realized with the aid of this pump.

THE Moscow Natural Eye Model

Pat. Feb. 3, 1914.

A New and Valuable Aid in Teaching Anatomy and
Physiology of the Eye

These models consist of a real, natural eye which has been hardened and fixed; then sectioned in half and mounted in a glass cell so as to show all the internal parts of the eye ball. These structures are all held in their normal positions, and may be easily identified by means of the diagrammatic cut, keyed to model, which accompanies each one.

The Moscow Natural Eye Models are excellent preparations. We find them to be a great help in laboratory work, in Zoology, Physiology, Anatomy, etc., etc. Dr. J. E. Wodsdalek, Professor of Zoology, University of Idaho.

Mounted in ebonized box with hinged cover, which protects the glass cell from injury. Absolutely permanent, and fully guaranteed.

A NEW INVENTION

The Leitz Binocular Microscope with Single Objective

This instrument causes quite a revolution in the microscope technique.

The Binocular Microscope can be used with low and high powers, including Oil-Immersion.

In viewing with the Binocular Microscope, the increase in quality of the image is remarkable.

One can see the preparation so much clearer, and has the impression of observing more details than are usually noticeable with the Monocular type of microscope stand.

Very seldom are both eyes the same in strength, or in power of accommodation, but in binocular vision when it is possible for them to compensate for one another, both eyes can utilize their optical properties to the fullest extent. One eye may be more inclined as far as sensitiveness for color is concerned, and the other with reference to penetrating power; and in making use of both eyes at the same time, these faculties combined increase to a great extent the distinctness and brilliancy of the image.

If we compare the image of a Monocular Microscope with an image obtained with both eyes, we are mistaken in claiming that we see the object more clearly, but we do observe the image with more life, and the impression of the presence of an increased brilliancy is created.

After endeavoring to give a brief description of the possibilities and effects obtained with the "*New Leitz Binocular Microscope with Single Objective*" we deem it advisable to summarize the advantages in the following:

- 1st. Binocular vision even with eyes of different refraction.
- 2d. Oculars can be adjusted to any inter-pupillary distance.
- 3d. One ocular allows for adaptation, so as to overcome any difference of refraction in the observer's eyes.
- 4th. Greatest restfulness to the eyes, and accordingly an increase in quality of microscopical examinations.
- 5th. The vividity (expression for brilliancy and life in images under observation) is carried to a remarkable degree, not obtained to any noticeable extent in microscopes of monocular vision.
- 6th. Apparent stereoscopic effect, suggested to the observer's eyes, due to the brilliancy, life and contrast created in binocular vision.
- 7th. Any existing microscope objective, from lowest to highest power, can be utilized, thus making unnecessary an investment in a special optical equipment—with the exception of oculars only.

The descriptive circular lists Duty Free prices on the Microscope stand as well as suitable Achromatic Semi-Apochromatic and Apechromatic Equipments.

Garrison's History of Medicine

THE BAEDEKER OF MEDICAL HISTORY

This book presents the history of medicine from the earliest ancient and primitive times, on through Egyptian medicine, Sumerian and Oriental medicine, Greek medicine, the Byzantine period; the Mohammedan and Jewish periods, the Mediaeval period, the period of the Renaissance, the revival of learning and the Reformation; the Seventeenth Century (the age of individual scientific endeavor), the Eighteenth Century (the age of theories and systems), the Nineteenth Century (the beginning of organized advancement of science), the Twentieth Century (the beginning of organized preventive medicine). There are also Appendices covering Medical Chronology (data on important diseases, drugs, therapeutic procedures, surgical operations), Bibliographic Notes for Collateral Reading, and Test Questions.

The illustrations will stimulate the reader's interest in the picturesque aspects of medicine and in the personalities of its great leaders. The biographies are confined to the important facts and to interesting personal traits. Each period is followed by a survey of its social and cultural phases.

The Lancet, London

"A careful study of Dr. Garrison's book warrants us in saying that it is the best general history of medicine at present to be found in the English language."

A FEW FEATURES

All the important facts in medical history in compact form.

The only work in which the *modern period* is exhaustively treated to date. One half the volume deals with the Nineteenth and Twentieth Centuries.

A *biographic dictionary* of the men who have "done things," arranged alphabetically.

An album of *medical portraits*, many of them rare.

Full *bibliographic references* to all the discoveries and experiments of importance.

A very complete *medical chronology* (data on important diseases, drugs, therapeutic procedures, surgical operations).

A series of *test questions*.

Octavo of 763 pages, with many illustrations. By FIELDING H. GARRISON, M.D., Principal Assistant Librarian, Surgeon General's Office, Washington, D. C. Cloth, \$6.00 net; Half Morocco, \$7.50 net.

Philadelphia and London

New Scientific Journals

The Annals of the Bolus Herbarium. Edited by H. H. W. PEARSON, Harry Bolus Professor of Botany in the South African College, Capetown; Hon. Director, National Botanic Gardens, Kirstenbosch.

The *Annals* will be mainly concerned with botanical work directly or indirectly inspired by Dr. Bolus and with investigations conducted in or in connection with the Bolus Herbarium and contributing to knowledge of the vegetation of South Africa—in particular of its taxonomy, ecology, economic and geographical botany.

Subscription price, \$3.75; single copies, \$1.25

Annals of Applied Biology. Edited for the Association of Economic Biologists by Professor H. MAXWELL LEFROY.

A quarterly journal devoted to the interests of scientific agriculture. It is of special importance to advanced workers in entomology, plant disease, diseases of animals, and forestry, and of great practical value to agricultural colleges, experiment stations, and departments of public health.

[Subscription price, \$6.00; single copies, \$2.00

The Journal of Ecology. Edited for the British Ecological Society by FRANK CAVERS.

An international quarterly journal which aims to give a comprehensive review of progress in the entire field of ecology—including in its scope not only the relationships of plants to their environment but also the interrelationship between plants and animals.

Subscription price, \$3.75; single copies, \$1.25

Subscriptions are received for volumes only. Prices on back volumes vary, and postage from London is charged on back volumes and single numbers.

THE papers read before the American Association of Museums during the eight years of its life have covered a wide range of topics, reaching, one might imagine, the whole circle of museum interests. Yet there is one question, antecedent to all others, which has never been asked, and but once approached, in your presence. This is the question: Just what use are all these papers? We meet to develop and exchange our ideas; but when we separate, what power have we to put into effect what we have concluded and learned? We have the voice here. How much voice have we at home?

This question of official scope we share with every similar association; and with several it has recently become a burning question. Just a year ago there was formed an association of university professors for the determination and maintenance of professorial rights; and last winter the American Political Science Association and the Philosophical and Psychological Associations appointed committees to consider and report upon like matters.

A problem of problems like this offers appropriate matter for an initial presidential address; and its simultaneous agitation elsewhere suggests treating it in the broadest possible way—as a concern, not of one profession, but of all professions. Thus amplified, the topic becomes that of the present and future status of the specialist in the United States. Far as this theme stretches beyond the work of the permanent

¹ Presidential address, given at the ninth annual meeting of the American Association of Museums, held in Milwaukee, May 19–21, 1914.

public exhibitions we call museums, the inquiry into the day of the expert is one that vitally touches the whole official activity of every museum worker. The inquiry naturally divides itself into four:

What has been the position of the expert among us?

What change suggests itself?

What are the bearings of change?

What are the prospects of change?

We shall offer replies to these questions in succession: (1) by arguing that the prevailing attitude of institutions of the humanities in this country toward their expert employees is out of date; (2) by specifying a reform that would bring it up to date; (3) by meeting criticism of the new order; and (4) by noting its approach. We shall describe an outgrown condition, state and defend an adjustment, and report progress toward it. A glimpse of the past will lead to a glimpse of the future.

By expert will here be meant a person whose achievements demand special aptitudes long exercised; and by his day a time when these developed abilities are used to the best advantage of the community.

For the expert in this country, to-day, according to frequent remark, is not such a time; but there are signs that to-morrow will be.

Here and now, the work of the expert is largely carried on as a branch of corporate activity. Our men of science, pure and applied, our lawyers, doctors, educators, clergymen, social workers, artists and students of art, while they may practise their specialties alone, very commonly also serve some corporation, and in great numbers serve a corporation exclusively, as do most of us assembled here.

A corporation is a body of men empowered by the state to join in a certain purpose, and held responsible for its due fulfilment. At the end of his brief and hamp-

ered career as premier of England, Lord Rosebery is reported to have said: "Responsibility without power is hell." To be discharged successfully, duty must be coupled with corresponding authority. This is the foundation principle with which any study of the corporate sphere of the expert must begin.

A corporation engaging the aid of a staff is responsible at once for every detail of their action in its service, and for every detail of their outside life, in so far as this reacts upon their official activity; and hence possesses equivalent rights of control, subject only to law and custom.

Rights of total control presuppose in turn competence for total control. To ensure it, two methods of selecting the membership of a corporation are possible. In giving a certain purpose into the sole charge of certain persons, regard may be had either to the purpose chiefly, or to the persons chiefly; to their special competence, or to their general competence.

In the history of this country, the choice among men of the professions concerned was a colonial method; that among men of ability, however displayed, has been our national method.

The colonial method was an inheritance from the old world. Leonardo da Vinci is spoken of as the last European to take all knowledge for his province. With the development of the sciences and the arts after him, even men of commanding powers became specialists. Following the example of the mother country, the colonies placed their first colleges under the control of educational experts—in the main their clerics par excellence, or clergymen. An interpretation of the charter of Harvard College of 1636 given later by the colonial legislature, affirmed that the corporation was restricted to members of the teaching force; as the corporations of Oxford and Cambridge in

England still are. The charter of Yale College was issued in 1701 to ten clergymen, and provided that their successors should always be clergymen.

At the birth of our nation, the emphasis turned from purposes to persons, under the compelling force of two causes: the parity of our voting citizens, and the conditions of a new national life.

From the beginning of the new union one man was as good as another at the polls. Every vote cast was given the same weight. It followed that the recognition of the likenesses of men became dominant, and the recognition of their differences obscured. Leading men came to be thought of as like exponents of the sense and efficiency of the community. The acknowledgement of competence took the form of an acknowledgment of general competence. We of the United States have been nurtured in the belief that a man who has distinguished himself in any one direction will also distinguish himself in any other.

Our early national experience confirmed the belief at every turn. Pioneer conditions bring out the all-round man. The solid citizen in a new community is called on to be at once a farmer for sustenance, a manufacturer for clothing, a builder for shelter and a soldier for defence; often also a lawyer for justice, a doctor for the body, an educator for the mind or a teacher for the soul. The nascent civilization of the United States had its Leonardo da Vinci in Benjamin Franklin. Nor has our later progress yet thoroughly dislodged the ideal of the all-round American, fit for any task. The subjugation of a continent is in the main a business matter, and an able man may learn a business in all its branches. The practise of naming any capable person for any office has maintained itself among us because surpassing excellence has not for the most part been essen-

tial. We have fought successful wars with citizen soldiery and grown great in peace with practical men as intellectual guides. To Amiel our democracy announced an era of mediocrity; Schopenhauer called us a nation of plebeians; an Austrian royal visitor missed among us the sense of personality—the perception of that delicate but real differentiation that makes each man himself and no one else. This is the mark left on the society of the United States by our day of small things.

That day is now past; and it behooves us to examine the foundations of the emphasis which our methods of assigning responsibility impose upon persons instead of upon purposes, upon general repute instead of special fitness. When examined, our course proves an aberration from that of colonial times learned in Europe. We must go back upon history; but only to go on to a new social ideal which shall square at once with our political creed and our existing national conditions.

First, as to our political creed. The parity of voters obscures, but also implies the difference of men's capacity. In affirming that persons of a certain sex and reaching certain mental, moral and economical standards should be counted alike in the process of government, it presupposes others who do not possess these qualifications and are not to be counted at all. The conception of the equal distribution of capacity among men is negated by the political device itself which fostered it.

It may be asked: What then becomes of the belief that men are created equal? If that renowned assertion does not mean that one man is as good as another, that all persons would show like capacity with like opportunity, what does it mean? Something totally different. Did it claim that every babe newborn might under favorable circumstances become what any other may, it

would seek to persuade us that males might become mothers. Instead of this and other absurdities but little less glaring, it proclaims the logical postulate that all real differences of human capacity are sensible facts of the present world. In Jefferson's glowing words, the inhabitants of this created frame bring none of their disparities with them from the invisible. There are no such things as divine rights, withdrawn from human scrutiny. The doctrine of equality affirms that only those persons who show themselves different should be treated differently. Its motto is the Roman challenge "*Aut tace, aut face*"—in modern American "Put up or shut up." True democracy is scientific method applied in politics. It accepts as inevitable in the political sphere also what Huxley called the great tragedy of science—"the slaughter of a beautiful theory by an ugly fact." The belief that a man who has shown exceptional powers in any one direction will also show them in any other is such a beautiful theory, exposed by our political creed to slaughter by ugly facts. Within narrow limits they confirm it. A capable farmer or efficient selectman will in all probability prove a good teacher of the rule of three, or a good postmaster. Beyond narrow limits they disprove it. Probably neither could teach Abelian functions well, or manage a wireless station. But whether verified or falsified, it is not the generalization itself, but the test of it, which is the sum and substance of the principle of equality. This is a doctrine of method, not a statement of results. It repeats in modern words the ancient injunction—"By their fruits ye shall know them." It is the merit system generalized. Admitting all verifiable disparities of human capacity, and excluding all mystic disparities, the equality of the Declaration is simple common sense. Denying them all

indiscriminately, the equality of its interpretation is literally nonsense.

Second, as to our national conditions. They are no longer those of pioneer life. The task of leading the civilization of the United States has ceased to resemble a business. No man, however able, can learn it in all its branches. Growth, as it is wont, has developed heterogeneity from homogeneity. The arts we now practise have become as long as the lives we can devote to them. Our farmers, our manufacturers, our builders, our soldiers, our lawyers, our doctors, our educators, our religious leaders, are now different persons, each given wholly to his work. The era of the all-round man has at last gone by for us also, as centuries ago it went by for the old world. The excellence that comes alone from the long exercise of special aptitude is everywhere demanded, and the demand is everywhere being met. The era of mediocrity, the nation of plebeians, is on its way to bringing forth aristocracies of demonstrated ability, and the sense of personality—the recognition of that delicate but real differentiation that makes each man himself and no one else—will not long delay its advent.

The democracy of individuality, the democracy that accepts all proven differences and no others, is the new social ideal, squaring at once with the creed of our fathers and our own conditions. With our political creed, for the doctrine of equality, in denying all supersensible differences, stops short at the sensible world. Personality is its presupposition. With our national conditions, for the all-round man is bested in every line by the exceptional man in that line, and only the best has become good enough for us. The Jack-of-all-trades is master of none, and our progress calls for masters everywhere. Finally, the democracy of individuality makes for the union

in which there is strength. The new ideal is not that of a society of persons increasingly like each other, and hence increasingly sufficient each to himself, but of persons increasingly different each from the other, and hence increasingly necessary each to the other. While the Declaration proclaimed our independence of other peoples, it assumed our interdependence among ourselves. A citizenship of similars is like the sand, composed of particles each as complete as any and with no tendency to cohere; and a political house built upon it will fall. A citizenship of dissimilars is like the rock, composed of particles supplementing and cleaving to each other; and a political house built upon it will stand.

But we have not yet acquired the courage of our fundamental political conviction, nor yet thoroughly adjusted ourselves to our larger life. The administration of collective enterprises in the United States is at present in a state of unstable equilibrium. The question of the corporate sphere of the expert is not yet settled because not yet settled right.

While the actual fulfilment of corporate purposes has in general grown beyond the competence of any but those of special aptitude long exercised, our national habit persists of placing these purposes in charge of men of ability however displayed. Any conspicuous success, especially financial success, opens the way to a position of corporate authority. The necessary result is a permissive system of control. A corporation among us executes its trust by choosing paid assistants of the special ability required, and permitting them to carry out its purposes more or less in their own way. This situation of power perforce in abeyance is one of unstable administrative equilibrium. What is permitted can also be forbidden, and may at any time be forbidden by an authority alive to its responsibility

and conscious of its power. In this event two rights to control come into conflict: the right based on capacity and the right based on law. The uncertainty of the situation is plain in the case of institutions of the humanities. Only an Orientalist can determine what antecedent study should be demanded for a course in the Vedas, only a technician whether quaternions should be used in teaching engineering, only an experimenter when a culture should be transferred from sun to shade, only a librarian what system of shelf numbering is applicable to fiction, only a surgeon how to conduct an operation in tracheotomy, only a religious leader to what spiritual exercise to invite a soul in need, only a curator how to install an ecological exhibit or make a collection of prints tell on the public, only an alienist how to control *melancholia agitans*, only a social worker how far the same methods of help are fitted to Syrians and Chinese. Yet others make up the boards on whose responsibility, by whose authority, and at whose option such decisions are taken. The permissive system settles the question of the corporate sphere of the expert but temporarily; leaving competence subject to impotence. It presents a problem, and one only to be solved by the union of the two potentially opposing rights. In the end, capacity must be given a legal standing. The skill demanded of the employee must be represented among the employers.

In contrast with the permissive system of control, that exercised according to this conclusion by a mixed board may be called the positive system. The terms refer respectively to the power of veto and the power of fiat. The positive system proposes that a corporation shall be constituted with a competence as all-embracing as its authority. Concretely, and considering charitable foundations only, it proposes that pro-

fessors in our colleges and technical schools shall be represented among the trustees of those institutions, librarians and heads of departments among those of libraries, scientific men among those of institutions of research, physicians among those of hospitals, clergymen among those of religious establishments, directors and curators among those of museums, social workers among those of foundations for popular betterment. In the most general terms it claims that any corporation should include members embodying in their own persons the special types of skill essential in carrying on its work. This claim is based on the conditions of permanent efficiency in collective enterprises. Its recognition is growing among us and will one day be general. That day will be the day of the expert.

Such a change in the make-up of corporations in this country may be said to round out an organization which practical sagacity has already partially developed in foundations of private origin and public aim among us. The men of general repute which it has been our custom to choose for positions of charitable trust have acquired by the logic of events their special necessary function in the fulfilment of these trusts. This function is that of winning support for the institutions they control. In our own country more than in any other, corporations not for profit are the fruit of private initiative. The first requisite for their establishment and maintenance is the selection of a board of trustees whose names, with those of their successors, will be an earnest of coming gifts because a guarantee of their safe and conscientious handling. Before we can do anything, we must have something to do with. But although ample and assured support is a condition necessary to the success of an institution, it is not a condition

sufficient to success. A function equally necessary, and with support sufficient, is that of the accomplishment of purpose. This is the second and no less exacting half of the task; with us overshadowed by the first, because the accumulation of our wealth has outrun our provision of knowledge and skill to utilize it. The positive system of control repairs this omission, now out of date. It supplements our present provision of means by providing also for ends. It would impose the total charge of an institution upon a body fitted to bear both halves of it. Neither the men of social and financial standing who now compose the boards of our charitable institutions, nor the specialists now active in their aid, but now commonly excluded from those boards, are equal to the whole duty. Only men of affairs are competent to the business management of their trust. Only men in comparison withdrawn from the public eye in the long exercise of special aptitudes are competent to its professional conduct. The men of means and the men of ends must join forces in order to the best achievement of their common purpose.

The practical application of the principle of control by mixed boards presents various questions.

Is the demand that all the different forms of professional skill utilized by a corporation shall be represented therein an ideal realizable in the instance of large institutions? Theoretically no; practically yes. All the expert ability employed will in a measure be represented by each professional member; and by rotation in office among them, the recurrent grasp by the board of the affairs of the foundation may be extended to minutiae in any degree.

Again, is it wise to place experts in charge of experts? The point may be debated, but is irrelevant. The positive sys-

tem does not propose to do so, but to give them a share in controlling others. The question—Who shall decide when doctors disagree?—finds its answer when another equal authority is present to add considerations beyond the scope of either. Such deciding voices are provided for in the mixed boards contemplated in the positive system. Its ideal is that every form of consideration which enters into the work in hand shall have its representative in the body which controls.

Again, should the experts employed by a charitable corporation be eligible thereto, or ought its professional membership to be chosen outside? Choice from the staff suggests a double doubt. Suppose a superior officer and his subordinate chosen; would not their equality on the board weaken the administrative control of the superior? No; for the equality is that of ultimate authority. The superior exercises his control as the delegate of the inferior as well as of himself and others. The inferior who disputed it would question his own right. There is no surer means of interesting any one in subordination than to give him power.

The doubt has another bearing. It also reflects the importance of the individual interests at stake in the case of employees. Will not their concern for their pay, as a rule, dominate their concern for their work?

The democracy of similarity says yes. The craving for money is the dominating motive in all men at all times. The democracy of individuality says no—basing its reply on a distinction. As social affairs are now arranged, some money is a perpetual necessity to us all, hardly less inexorable than the air we breathe. Else why should men and women still starve among us? But more money is an increasing luxury, the desire for which may be outweighed by many other interests. The *auri sacra fames* is an

illegitimate child of the hunger for bread. In the case of the paid expert in a charitable corporation, some money is at most times assured, and motives are at all times present capable of tempering the desire for more. There are thus two reasons why his interest in his pay will not certainly dominate his interest in his work. His salary, while always moderate, is within limits safe; and the long exercise of his special aptitudes is at once fruit and source of motives apart from those of gain. The patience with which the specialist follows his task is the result of the fascinating germinal power of the ideas upon it of which his brain is the theater, and which his hand transfers to real life. They may become an efficient anti-toxin for the *cacoethes habendi*. Those who have had much to do with experts can echo the statement of Renan—"The reason why my judgments of human nature are a surprise to men of the world is that they have not seen what I have seen." To admit a rule by which experts when paid shall be excluded from charitable boards is to commit the absurdity of at once recognizing the exceptional man and treating him as if he were like all other men. Other grounds of bias—the desires for honor and power—unpaid members share with him. The receipt of pay as well will not disqualify those worthy of it.

Again, how are the permissive and the positive systems, respectively, related to the rights of free thought and free speech? These universal rights, so-called, are in essence duties of men in power. They should see to it that they do not so uphold the social order as to bar its advance. While all authority, therefore, is obligated to reduce to a minimum its repression of ideas and their utterance, no organization of control will absolutely prevent all danger of too high an interpretation of this minimum.

But a system by which seekers after truth in corporate service themselves share in the management tends to keep it within bounds. The positive system of corporate control thus obviates a danger to freedom inherent in the permissive system. It comes to the aid of free thought and free speech, entails a liberation of the spiritual forces within a nation.

The inclusion in charitable boards of men experienced in the actual accomplishment of their purposes is not new in this country either as a fact or an ideal. Their representation, never wholly lacking, is growing, and its extension is advocated with authority.

Frequently, if not commonly, a single chief executive officer, the head of the staff, is included in the board of trustees. The old ideal of the all-round man lingers in this provision, here swollen to impossible proportions. The admitted difficulty of finding satisfactory executive heads for institutions of the humanities is the sign of an unreasonable demand upon human capacity. No single executive, however active and talented, can embody in himself various types of modern professional knowledge and skill. The due representation of men of ends in any considerable corporation will always be a number greater than unity. A fair fraction of the board must be selected from their ranks. The demand upon the executive is thereby decreased to the manageable proportions of a business leadership, either with or without a special professional function.

Specialists have found a place already in a number of our scientific and artistic corporations. The charter of a noted scientific school, affiliated with a university, stipulates that of the corporation of nine, one third shall always be professors or ex-professors of the school. In another institute a larger proportion are persons in im-

mediate control of the scientific work. No commanding need of appeal to the community for financial support existing in these cases, the men of ends have taken their natural place in the management along with men of means. Among museums of art more than one has chosen trustees from its own working staff and those of neighboring institutions.

In our chief universities, it has become the practise to allow the alumni a large representation in the board of trustees. Of the two bodies of persons concerned in the actual achievement of the teaching purpose—the teachers and the taught—this practise accords to one—the taught—its share in ultimate management. The step suggests, and may be believed to announce, a second, by which the other body—the teachers—will gain a similar representation. The class of alumni trustees has for its logical complement a class of faculty trustees; a class more indispensable to vital university success than their predecessors, in that they represent not the subjects but the source of university discipline.

The step has found prominent advocates. In the *Atlantic Monthly* for September, 1905, President Pritchett asks "Shall the university become a business corporation?" He suggests that the business of graduating men has little to do with the art of educating them, and concludes

In the settlement of the larger questions of administration . . . may not some council composed of trustees and faculty jointly share the responsibility to advantage? . . . To-day we need, in my judgment, to concern ourselves in the university with the spiritual side of administration.

In articles entitled "University Control" published in *SCIENCE* in 1906 and 1912, Professor Cattell proposes that professors should take their place with alumni and interested members of the community in the corporation of a university, and re-

ports favoring opinions from a large majority of those holding the most important scientific chairs in the country. In his report for 1911-12 as president of Cornell University, Dr. Schurman writes:

The only ultimately satisfactory solution of the problem of the government of our universities is the concession to the professorate of representation on the board of trustees or regents.

Such agreement in a recommendation is a prophecy of its acceptance.

When the day of the expert arrives, every corporation employing specialists will have its class of professional members, whether in a majority or a minority, whether chosen within or outside the staff, whether for limited periods or without term. Historical causes have both denied and begun to restore to expert ability in this country a place in the corporations to whose work it is necessary. The system of positive control by mixed boards is a final settlement of the question of the corporate sphere of the expert because the right settlement, granting to competence its share in the management of competence. The day of the expert brightens on the horizon. Let us welcome its advancing beams. Either we ourselves, or our early successors; will be called to labor in its full sunshine.

BENJAMIN IVES GILMAN

April 15, 1914

A TRIBUTE TO DR. HENRY P. WALCOTT

THE following letter was presented to Dr. Henry P. Walcott on the occasion of his retirement from the Massachusetts State Board of Health:

TO HENRY P. WALCOTT, M.D., LL.D., CHAIRMAN,
MASSACHUSETTS STATE BOARD OF HEALTH;
FROM TWENTY-TWO HUNDRED MEMBERS OF THE
MEDICAL PROFESSION OF THE STATE,—GREETING.

Sir: On the 19th day of May, 1914, your term as a member of the State Board of Health ends, and we understand you are not a candidate for reappointment.

Such an occasion can not be allowed to pass unnoticed, at least by those citizens who, as a class, should be most competent to gauge the value of such services to the state as yours have been.

The best appraisal of those services is the mention of some of them, with a brief statement of your relations to the board.

Your connection with the board began in 1880, 33 years ago, when, after ten years of independent existence, it had been merged with the conjoined Board of Lunacy and Charity, and you were unanimously elected its health officer. At this time, you served on a commission for the sanitary improvement of the Blackstone River, a precursor of your subsequent labors on similar problems.

In 1886, by an act of the legislature, the Board of Health once more entered upon an independent existence. You were appointed a member for a seven years' term by Governor Robinson, a Republican, with the advice and consent of the senate, and became the chairman. You have since been re-appointed three times for terms of seven years: once by Governor Russell, a Democrat, in 1893; once by Governor Crane, Republican, in 1900; and once by Governor Guild, Republican, in 1907. Since 1886, you have always continued as chairman of the board.

Early in 1894, you began to consider the advisability of establishing a laboratory for the free production and distribution of diphtheria antitoxin; and such curative serum was actually distributed early in 1895, being the first so distributed in any state. This was made possible through the co-operation of Harvard University, secured by your influence, at the Bussey Institution, and was carried on for nine years—during this time as well as later under the personal direction of Dr. Theobald Smith—until 1903, when the legislature enacted a law authorizing the State Board of Health to produce and distribute antitoxin and vaccine virus. Again through your influence, a laboratory was built on the grounds of the Bussey Institution where the preparation of antitoxin and animal vaccine was carried on together.

Within the last four years, you have served as chairman of two state commissions appointed to consider various important tuberculosis problems: one in 1910, and one in 1912. Reports were made to the legislature and printed as public documents.

It is impossible to separate your work in connection with the Board of Health from that in connection with the North and South Metropolitan Sewerage Systems, the Charles River Valley System, the Charles River estuary improvement, the

Metropolitan Water Supply, and numerous other similar problems of perhaps secondary importance, such as the improvement of the Neponset River Valley, of the Concord and Sudbury rivers, of the sanitary conditions as respects water supply, sewerage, and sewerage disposal of many cities and towns which have been devised by the committee on water supply and sewerage of the Board of Health, of which Mr. Hiram F. Mills is chairman, and carried out in connection with its recommendations under your chairmanship of the board.

Since the reestablishment of the State Board of Health in 1886, under your chairmanship, it has been the custom of the legislature to refer all important sanitary questions to that board for investigation and advice, instead of creating special commissions, as obtains in many states. This custom, under your wise administration, has doubtless saved much money to the state and, at the same time, secured sanitary improvements recognized in all civilized countries as the best of their class.

The investigations and recommendations of the board have commended themselves to the legislature and in general have been carried out ultimately as presented.

From 1886 to the present time, you have been constantly and steadfastly facing these great and grave problems. Since 1895 when the State Board of Health made its report to the legislature, presenting a plan for the water supply of the city of Boston and the surrounding cities and towns, have been added to your responsibilities those of a commissionership on the Metropolitan Water Board. You have borne the responsibilities both of recommendation and of execution. . . .

You have met the responsibilities then assumed with such wisdom, discretion and rare modesty, as to make the task of your successor who would uphold the standards bequeathed to him a difficult one indeed.

*THE EIGHTH REPORT OF THE CARNEGIE
FOUNDATION FOR THE ADVANCE-
MENT OF TEACHING*

THE eighth annual report of the president of the Carnegie Foundation for the Advancement of Teaching shows a total endowment of \$15,325,000, and an expenditure for the year ending September 30, 1913, of \$658,431. Of this \$519,440 were distributed in retiring allowances to professors, and \$80,949 in pensions to their widows, a total of \$600,390. Thirty-three allowances were granted during

the year, making the total in force 403, the average annual payment to an individual being \$1,703. The total distribution from the beginning has been \$2,936,927. The educational work of the foundation was separately endowed in January, 1913, by a gift of \$1,250,000 from Mr. Carnegie through the Carnegie Corporation of New York. This body, which is endowed with one hundred and twenty-five million dollars for "the advancement and diffusion of knowledge and understanding," has five ex-officio trustees, of whom one must always be the president of the Carnegie Foundation for the Advancement of Teaching.

In connection with the foundation's work as a center of information concerning pensions, the president discusses pension systems that are maintained by half a dozen colleges, the development of new systems at Brown University, the Rockefeller Institute, and the American Museum of Natural History, the new federated pension system of the English universities, and the proposed system for the clergy of the Episcopal Church. Among pensions for public school teachers the report discusses the misfortunes of the New York City system, and commends the plans of the new state system in Massachusetts.

Much of the report is devoted to the development of the educational work of the foundation into a separate division of educational enquiry. Its recent work includes a study of education in Vermont at the request of the Vermont Educational Commission, of legal education at the request of a committee of the American Bar Association, and of engineering education at the request of a joint committee representing the national engineering societies.

The study of education in Vermont, already distributed, represents the first survey that has been made of a state's educational activities as a whole. The study of legal education has been begun by a first-hand enquiry into the bar examinations of every state, a special study of legal teaching by Professor Josef Redlich, who came from Vienna for the purpose, and by a personal examination of each of the 160 law schools in the country. Plans for

the study of engineering education are now being completed. The earlier educational work of the foundation is continued in the report by commendation of the present tendency of college entrance requirements toward both elevation and flexibility. The need for further improvement is shown by the fact that only 55 per cent. of the students now in our colleges are high school graduates. The decrease in the number of medical schools in the country from 162 in 1910 to 115 in 1913, and the rapid improvement of the better schools are commented upon with appreciation. A general study of the problems of the state regulation of higher education is illustrated by a detailed account of the recent crisis in educational affairs in Iowa.

The report further presents a study of the financial status of college teachers as compared with the situation presented in a similar study published five years ago. The ordinary salary of a full professor in the institutions associated with the foundation is now \$3,000. During the last five years the salaries of instructors have risen by about \$80; those of junior professors show a gain of from \$120 to \$225; those of full professors show an increase from \$125 to \$350.

The report concludes with a frank criticism of contemporary college catalogues. It is accompanied by the annual report of the treasurer. Copies may be had by addressing the Foundation at 576 Fifth Avenue, New York City.

THE PRELIMINARY ANNOUNCEMENT OF
THE SAN FRANCISCO MEETING OF
THE AMERICAN ASSOCIATION
FOR THE ADVANCEMENT
OF SCIENCE

THE American Association for the Advancement of Science has decided to hold a general meeting of the association in San Francisco and vicinity on the occasion of the Panama-Pacific International Exposition, in 1915, and has appointed a Pacific Coast Committee of thirty-two members to make the necessary arrangements. This Committee has recommended, and the American Association has

approved, that the sessions of the meeting shall begin on Monday, August 2, and terminate on Saturday, August 7. It has been decided that:

(1) The general sessions of the meeting shall be held in San Francisco.

(2) The general evening lectures shall be delivered in San Francisco.

(3) The sessions for the presentation of addresses and papers in the separate divisions of science shall be held chiefly at the University of California, Berkeley.

(4) Sessions for the presentation of addresses and papers in the separate divisions of science shall be held on one day at Stanford University.

Subcommittees of the Pacific Coast Committee will in due time supply information to the members of the American Association and to the members of such other scientific societies as desire it: on transportation, by railroads and by steamers, including the Panama Canal route; on living accommodations in San Francisco and vicinity, and at other Pacific Coast points; on excursions; on the leading features of the Panama-Pacific International Exposition, and on other subjects of interest.

Holding in mind that the San Francisco events of 1915 are in commemoration of the union of the Atlantic and the Pacific, through the medium of the finished Panama Canal, and that the Pacific region is hereafter to be in closer relation with the states and nations lying east of the Cordilleras of North and South America, and with the nations of Europe, the Pacific Committee on Scientific Program has adopted the following resolution:

In view of the fact that the occurrence of scientific meetings in San Francisco in 1915 is in a manner a part of the celebration commemorating the opening of the Pacific to the peoples bordering the Atlantic it seems fitting that the program of meetings held in connection with this celebration should relate, as far as possible, to problems of world interest which pertain especially to the Pacific area.

The committee desires to add, by way of comment, that this resolution is not intended to discourage the presentation of worthy

papers on any subject whatsoever, but is merely to lay emphasis upon the desirability of papers on subjects concerning the Pacific region.

There will be four general sessions for the delivery of addresses by eminent men on subjects of wide interest. There will be many simultaneous or alternating meetings for the presentation of addresses and papers in the principal division of scientific knowledge. It is proposed that certain half days or whole days of the week be left free from scientific programs in the respective divisions in order that members and others in attendance may visit the exposition and other points of special interest in the vicinity.

The Pacific Coast Committee hopes that the 1915 meeting of the American Association, at a point so far removed from the usual meeting places of the general and special scientific societies of America and from the homes of their members, may be remarkable for the number of members of these societies in attendance and for the wide interest and high standard of the addresses and papers presented.

Please address correspondence to Albert L. Barrows, University of California Library, Berkeley, California.

SCIENTIFIC NOTES AND NEWS

A COMMITTEE has been formed in France, under the patronage of M. Poincaré, president of the Republic, for the erection of a monument in honor of J. H. Fabre, the famous entomologist. The idea is, not only to erect a monument at Serignan, but to preserve and to convert into a museum the estate of Harnas, the dwelling of the great naturalist. Subscriptions are asked from naturalists all over the world, and may be sent to the president of the committee, M. Henri de la Paillette, mayor of Serignan (Vaucluse), France.

THE medical faculty of Turin has decided to erect a memorial to the distinguished physiologist, Angelo Mosso, in the institute in which he taught for many years. The memorial will be unveiled on November 14, 1914,

the fourth anniversary of Mosso's death. Contributions should be sent to Professor Alberto Aggazzotti, Corso Raffaello, Torino.

REAR ADMIRAL ROBERT E. PEARY, U. S. N., retired, has received the gold medal conferred upon him by the French Geographical Society on April 24.

DR. BEVERLY T. GALLOWAY, newly appointed director of the New York State College of Agriculture, Cornell University, has formally resigned his office of assistant secretary of the U. S. Department of Agriculture.

In addition to the Elliott Cresson medals presented by the Franklin Institute, Philadelphia, to Dr. Smith and Mr. Wright, noted in the last issue of *SCIENCE*, medals were awarded and forwarded through the department of state to Professor Linde and Professor Eder. The grounds of the awards are stated by the committee as follows:

Karl Paul Gottfried Linde, Ph.D., in recognition of his scientific investigations of the processes of refrigeration and the liquefaction of gases and of his inventions of machinery for applying these processes in the manufacture of ice and for the purposes of cold storage.

Edgar Fahs Smith, Ph.D., Sc.D., LL.D., in recognition of his leading work in the field of electrochemistry, of his many contributions to the literature of chemical science, and of his great service in university education.

Joseph Maria Eder, Ph.D., in recognition of his important original researches in the science of photo-chemistry and of his many valuable contributions to the literature of that science and of the graphic arts.

Orville Wright, B.S., LL.D., in recognition of the epoch-making work accomplished by him, at first together with his brother Wilbur and latterly alone, in establishing on a practical basis the science and art of aviation.

LEWIS E. MOORE, professor of civil engineering at the Massachusetts Institute of Technology, has been appointed engineer of bridges and signals of the Massachusetts Public Service Commission, and resigned from the faculty of the institute.

DR. G. M. GUITERAS, of the Public Health Service, has been called to Tampico, Mexico, with the consent of the constitutional forces,

now in control of that place to "clean up" the city.

PREVOST HUBBARD, in charge division of roads and pavements, The Institute of Industrial Research, Washington, and Arthur H. Blanchard, professor of highway engineering at Columbia University, have been elected by the council of the International Association for Testing Materials the American members of a commission on "Standardization of Methods of Testing and Nomenclature of Road and Paving Materials."

SELSKAR M. GUNN, professor of biology in the department of sanitary biology and public health at the Massachusetts Institute of Technology, has been made managing editor of the *American Journal of Public Health* succeeding Dr. Livingston Farrand, formerly professor of anthropology at Columbia University, now president of the University of Colorado.

PROFESSOR DAVID EUGENE SMITH will represent Columbia University and the Bureau of Education at Washington at the Bacon Septenary celebration at Oxford on June 10, and at the Tercentenary Napier celebration at Edinburgh on July 22. He will spend the academic year 1914-1915 in travel abroad.

DR. J. P. IDDINGS, of the U. S. Geological Survey, will lecture at the University of London from June 4 to 9 on "Problems of Petrology." Mr. Iddings is on his way to the Netherlands, Indies and the islands of the South Pacific to study igneous rocks, traveling under the auspices of the Smithsonian Institution of Washington.

PRESIDENT R. C. MACLAURIN, of the Massachusetts Institute of Technology, is making a visit to the Pacific coast.

MESSRS. FREDERICK G. CLAPP and Myron L. Fuller, of the Associated Geological Engineers, Pittsburgh, are engaged in the examination of the northern parts of Chili and Shensi provinces in China for petroleum for the Standard Oil Company.

DR. ELWOOD S. MOORE, professor of geology and mineralogy at the Pennsylvania State

College, has been granted a year's leave of absence for 1914-15, and plans to spend it traveling abroad. He will sail from San Francisco on June 23, for Australia, in order to attend the annual meeting of the British Association for the Advancement of Science. After six months spent in Hawaii, New Zealand, and the East Indies he will study the balance of the time, until the fall of 1915, at the University of Berlin with Professor Krusch, of the department of economic geology.

THE annual stated meeting of the American Medico-Psychological Association is being held in Baltimore this week. A symposium on "Paresis" was announced for May 26. On the following day the annual address was delivered by Dr. Lewellys F. Barker on "The Relation of Internal Medicine to Psychiatry," and on the fourth day there was a symposium on "Eugenics."

MR. W. F. HILLEBRAND, chief chemist of the U. S. Bureau of Standards, lectured recently before the Cornell section of the American Chemical Society on "Chemistry at the Bureau of Standards."

THE Page-May memorial lectures of University College, London, for the current session will be delivered by Dr. Keith Lucas, whose subject will be "The Conduction of the Nervous Impulse." The course is given on Fridays, beginning on May 15.

PROFESSOR V. KARAPETOFF, of the department of electrical engineering, Cornell University, has completed an extended lecturing tour. His itinerary and topics were as follows: May 9, Springfield, Mass., an address before the Eastern Association of Physics Teachers on the subject of "Some Calculations in the Magnetic Circuit." May 11, Cleveland, Ohio, an address before the engineering students of the Case School of Applied Science on "The Production of a Revolving Magnetic Field." On the same day, a lecture before the Case School chapter of the Society of Sigma Xi on "The Dielectric Circuit." On Tuesday, May 12, an address before the engineering students of the Carnegie Institute of Technology,

Pittsburgh, on "Some Transient Electrical Phenomena," and on the evening of the same day, a paper before the Pittsburgh section of the American Institute of Electrical Engineers, a paper on "The Preparation and Qualifications of a Teacher in Engineering." On May 13, he addressed the students of the University of Pittsburgh on the "Electrification of Steam Railroads."

At the University of Glasgow on commemoration day, June 23, an oration on Lord Lister will be delivered by Sir Hector C. Cameron.

PROFESSOR RUDOLF TOMBO, JR., of the department of Germanic languages, Columbia University, known also to readers of this journal for his articles on "University Registration Statistics," died on May 22.

WE regret also to record the death of Mr. Herman Frasch, the industrial chemist, at one time chief chemist of the Standard Oil Company.

UNIVERSITY AND EDUCATIONAL NEWS

LAFAYETTE COLLEGE is a beneficiary in the will of Mr. William Runkle to the amount of \$100,000.

THE South Wales and Monmouthshire University College at Cardiff has received from an anonymous donor funds for the erection of a school of preventive medicine. The money value of this gift, together with that of Sir William James Thomas to erect a school for other branches of medicine in connection with the college, is estimated at £180,000.

THE cornerstone of the Julius Rosenwald Hall at the University of Chicago will be laid on the morning of Convocation Day, June 9. The address will be given by Professor T. C. Chamberlin, head of the department of geology, who has been connected with the university since its founding.

THE new building of the department of forestry of the New York State College of Agriculture was formally opened on May 15. Among those who made addresses were Professor James W. Toumey, director of the Yale

Forest School; Dr. Henry S. Drinker, president of Lehigh University, Mr. Gifford Pinchot and Dr. L. H. Bailey.

THE fiftieth anniversary of the founding of the School of Mines at Columbia University is being celebrated this week. On Thursday night there is a reception in the gymnasium. On Friday morning there will be a convocation at which honorary degrees will be conferred upon a number of eminent graduates of the School of Mines, and there will be addresses by Professor H. S. Munroe, Mr. T. W. Rickard and Mr. Hennen Jennings. In the afternoon the first lecture on the Chandler Foundation will be given by Dr. Leo H. Baekeland. The celebration will close with a dinner at the Waldorf-Astoria in the evening, at which Professor J. F. Kemp will preside.

THE foundation stone of the new School of Tropical Medicine at Calcutta, for the site and laboratory of which the government of India has appropriated \$195,000, was laid recently by the governor of Bengal. The *Journal* of the American Medical Association states that the institute will accept students from all over the world, and it is hoped that students of medical research institutions of the United States may be sent to the school for study. Communications regarding the school should be addressed to Lieut.-Col. Leonard Rogers, I. M. S., Medical School, Calcutta.

A NEW department, that of hygiene and bacteriology, has been created at the University of Chicago by the board of trustees. The chairman of the department is Edwin Oakes Jordan, professor of bacteriology, and associated with him in the work of the department are Assistant Professor Norman MacLeod Harris and Dr. Paul Gustav Heinemann. During the present quarter also Associate Professor William Buchanan Wherry, of the University of Cincinnati college of medicine, is giving courses in advanced bacteriology and parasitology. The work in bacteriology was formerly included in the department of pathology and bacteriology, which now becomes the department of pathology, with Professor Ludvig Hektoen as head.

VARIOUS sub-departments of geology at Cornell University have been consolidated under one head and the committee of professors which has hitherto administered the affairs of the department has been dissolved. Professor Heinrich Ries has been appointed head of the department.

MONEY is being collected to endow a professorship of railroading in the Graduate School of Business and Administration of Harvard University, to be named in honor of Mr. James J. Hill.

DEGREES will be conferred at commencement upon 101 University of Illinois matriculants of the years 1868-92, who completed 36 term credits and did not receive degrees. The belated degrees will be conferred as of the classes to which they belonged. These were not granted at the usual time because the students did not follow courses exactly prescribed.

CHARLES SCHUCHERT, professor of paleontology, has been elected acting dean of the graduate school of Yale University for next year in the absence abroad of Dean Oertel.

DR. FREDERICK A. SANDERS, professor of physics of Syracuse University, has been appointed head of the physics department of Vassar College.

DR. C. C. ADAMS, of the zoology department of the University of Illinois, has accepted the position of assistant professor of forest zoology in the New York State College of Forestry at Syracuse University.

HERBERT FISHER MOORE, assistant professor of theoretical and applied mechanics in the engineering experiment station of the University of Illinois, has been promoted to be professor of engineering materials.

MR. E. R. BURDON has been appointed university lecturer in forestry at the University of Cambridge.

DISCUSSION AND CORRESPONDENCE

MODESTY OVERWORKED

TO THE EDITOR OF SCIENCE: I am very loath to be drawn into the controversy on nomen-

clature, but in a recent number of SCIENCE (April 24) Professor Verrill has seen fit to hold me up to obloquy for having wantonly violated two rules, one of which is of his own selection. I do not intend to discuss the advisability of this rule further than to enquire who is to be the arbiter of what is "obviously obscene"? Professor Verrill evidently regards *Urticina felina* as an appellation falling under this category, while others, equally modest, might reject *Metridium*, which he accepts with equanimity. Even granting that certain Linnean names in their original form might bring a blush to the cheek of some *casta Minerva*, are they therefore, in their modern associations, to be rejected on that ground alone? Surely such a principle, consistently applied, would deprive the world of many of its greatest possessions in science, literature and art! *Honi soit qui mal y pense!*

Nor do I intend to notice the personalities contained in Professor Verrill's letter, but, when he disputes the correctness of my conclusions as to the validity of the names *Metridium senile* and *Urticina felina* he is entering upon a criticism to which one may reply. His contention that *Priapus senilis* and *P. felinus* are unidentifiable from Linnaeus's descriptions I have fully recognized, but I also showed that Linnaeus himself, in the twelfth edition of the "Systema," furnished the basis for their correct identification, by giving as references for them the recognizable figures in Baster's "Opuscula subsciva," a work that Professor Verrill carefully refrains from mentioning. It is quite unnecessary to repeat here the facts and arguments in support of this view, as they are fully set forth in my paper, whose main object, so far as these two species were concerned, was to show that the confusion that has arisen in the synonymy of their Linnean names was quite unnecessary and that these names are valid according to the ordinary rules of priority. Professor Verrill thinks otherwise and prefers the specific terms *dianthus* and *crassicornis*; but why does he reject Pennant's *pentapetala*, which apparently antedates *dianthus*? Surely it, too, can

not be regarded as "obviously obscene" or rather let us say, immodest. My position, in brief, is that we have in Linnaeus's reference to Baster's figure very clear evidence of what he intended the term *felinus* to imply, and, this being so, the application of his term *senilis* also becomes clear. I prefer Linnaeus's identifications of his own species to any speculations as to other possibilities.

I am quite prepared to assume responsibility for having advocated the revival of the Linnean specific names for the two species in question, but Professor Verrill asserts that I also advocate the adoption of *Priapus equinus* for the form that he prefers to term *Actinia mesembryanthemum* (properly *mesembrianthemum*). I do not recall ever having advocated the use of the original Linnean name for this species, and, indeed, in the paper which has become the object for Professor Verrill's fulminations, it is only once mentioned and then as *Actinia (Priapus) equina*. I gave the name that form expressly to indicate that while recognizing the priority of *Priapus* according to the International Rules, I hoped that the long-established name of *Actinia* would not be dropped from our nomenclature. Apparently my mode of expressing this idea has been somewhat too subtle. It would, indeed, be unfortunate if *Actinia*, with all its associations, should be obliterated and it would also be unfortunate if the familiar *A. equina* should disappear. For Professor Verrill's statement that "the leading European authorities, familiar with the actinians of the same region, have never been able to agree as to his (*i. e.*, Linnaeus's) species" is quite erroneous so far as this species is concerned, and equally untrue is the statement that "most writers, before McMurrich, have wisely rejected the names," mainly on the ground of their immodesty. I have taken the trouble to look up the references to the species now under consideration during the twenty-five years that preceded the publication of my paper and find that in *thirty-eight* it is quoted as *A. equina* and only in *four* as *A. mesembryanthemum*, although in several the latter name is given as

a synonym for *equina*. Apparently there are quite a number of zoologists unburdened by such an exquisite sense of modesty as would compel them to reject this Linnean name, and the most convincing reason for the non-use of *senilis* and *felinus* has not been that stated by Professor Verrill, but, as a review of the literature will clearly show, the confusion in their application which early arose and to which I have referred in my paper.

J. PLAYFAIR McMURRICH

THE FANNY EMDEN PRIZE OF THE PARIS ACADEMY

TO THE EDITOR OF SCIENCE: It may be of interest to you to record the fact that the Academy of Sciences of the French Institute has published a statement in regard to the award of the Fanny Emden prize for the year 1913. This prize is of the value of 3,000 francs and is the result of a bequest made by Mlle. Juliette de Reinach of 50,000 francs, the interest of which is available every two years. The prize is to be awarded for the best work "in the field of hypnotism, suggestion or in general, of physiological action which may be exercised at a distance upon a living organism." The fund was made available in 1911. Thirteen candidates presented researches, but no prize was awarded. In 1913 the prize was divided, 2,000 francs to M. Emile Boirac and 1,000 francs to M. J. Ochorowicz.

The peculiar wording of the award lies in the fact that the Academy makes these awards as *encouragement* for meritorious work, but sets forth that neither of the essays submitted goes very far towards proving its thesis. Indeed, the report rather decidedly indicates that they contribute rather little towards the establishment of any conclusion. The report cites one or two experiments of M. Boirac which are certainly questionable, and require extraordinary confirmation before they can be regarded as evidential in the sense presented.

Nothing is indicated in the report to show that a research proving the absence of any such action "at a distance," or its extreme improbability, would not be considered; but the very wording of the original bequest seems

to suggest a leaning in favor of a positive conclusion. It is certainly to be regretted that a problem of this nature should receive even so partial endorsement as is implied by the French Academy of Science. Since the conditions of the prize do not require specific investigations, but make it available for an argument indicating the position of psychology on such an hypothesis, I trust that for 1915 some candidate will present a statement that will more adequately express the views of a considerable proportion of modern psychologists upon this subject. Psychology receives so slight a recognition in scientific competitions that it seems unfortunate that its interests should be prejudiced by a recognition of a subject somewhat tangential to its main problems, and yet one upon which it has been forced to express itself in view of the widespread public concern.

JOSEPH JASTROW

SCIENTIFIC BOOKS

Flies in Relation to Disease: Non-bloodsucking Flies. By G. S. GRAHAM-SMITH, M.D. Cambridge, University Press, 1913.

A first reading of Dr. Graham-Smith's admirable book is apt in a way to somewhat dampen the enthusiasm of the ardent fly crusader. This is especially apt to be the case with one who, like the present writer, has recently been told by Stiles, after his experiences in the Carolinas, that the half has not yet been told of the danger of the house-fly, and who only the other day heard Levy of Richmond, in an address before the State Health Association, emphatically state that even the most exaggerated newspaper statements of the dangers have underestimated them. Perhaps if Dr. Graham-Smith lived in the Carolinas or in Virginia he might share to a certain degree the views of Stiles and Levy, but, living in England, and being a most careful, conscientious, and thoroughly scientific laboratory worker, he has in this book held himself down to absolutely demonstrated statements and has viewed the problem almost strictly from the medical side. He has thus produced a work which will be highly pleas-

ing to conservative people who have diagnosed current newspaper statements about the house-fly as yellow journalism.

A second and more careful reading of the book, however, will show that there is an abundance of demonstrated facts upon which to base those vigorous anti-fly crusades. He states that it is certain that the house-fly is a potential disease carrier and a constant frequenter and disseminator of filth, "but," he says, "much remains to be done before Howard's name, 'the typhoid fly,' or Hewitt's generalization can be completely justified." Hewitt's generalization, by the way, is "It has been proved that the house-fly plays an important part in the dissemination of certain of our most prevalent infectious diseases when the necessary conditions are present." Both Hewitt and myself (quoting from Graham-Smith) "approaching the subject from the entomological standpoint, have based their conclusions in regard to disease mainly on evidence of an epidemiological character and have apparently accepted the bacteriological evidence almost without criticism. From the bacteriological point of view, however, while the evidence relating to the carriage of pathogenic bacilli by experimentally infected flies is fairly conclusive, that relating to the presence of these microorganisms in 'wild flies' is far from complete."

The book is a very thorough and a very cautious one, and covers a consideration of the species of non-bloodsucking flies found in houses, the life history of the house fly, its internal and external anatomy in much detail, its habits, the ways in which it carries and distributes bacteria, the bacteriology of city flies, the fate of organisms eaten by larvæ, and a lengthy consideration of typhoid fever, summer diarrhea, anthrax, other bacterial diseases, the carriage of the eggs of parasitic worms, myiasis, the diseases and parasites and other enemies of flies, and questions of control. It is an admirable compendium, containing many facts not hitherto presented, and bringing together the latest information in a way in which it can be easily and intelligently consulted.

On account of the conservatism of the author, great interest attaches to such statements as he makes concerning actual danger from flies. He shows that infected flies not only carry bacteria on their bodies and limbs, thereby contaminating substances over which they walk, but distribute bacteria which they have ingested, by means of vomit and fecal deposits. He shows that, while non-spore-bearing bacteria survive at the most only twenty-four hours on the limbs, flies nevertheless infect substances over which they walk with such organisms for several days by means of a fluid which they regurgitate from their crops. He also shows that the majority of the non-spore-bearing bacilli pass through the intestine and are in living condition in the fecal deposits. He states that flies feeding upon tubercular sputum suffer from diarrhea, a fact which may be of some importance in relation to their potentiality for spreading infection. He states that city flies carry in and on their bodies very large numbers of bacteria, many of which are fecal types and that these are more numerous in flies caught in congested or dirty areas. Pathogenic bacteria or allied types have been isolated from wild city flies. "Flies bred from larvæ living in material infected with anthrax spores are capable of communicating the disease for some days after they emerge."

He admits that the evidence is very strong that flies are the dominating factor in the dissemination of typhoid fever in military and other camps and in stations in the tropics, and that there is some evidence that they are factors in causing the autumnal increase in typhoid in England, but agrees with Chapin that it is unlikely that they play an important part in well-sewered towns. The evidence in epidemic diarrhea of children he thinks is not altogether conclusive, largely I imagine because, although the disease is admittedly infectious, the causative organism has not been identified with certainty. He considers that the annual mortality due to this disease is so great that "a serious attempt to conclusively ascertain the part played by

flies in its dissemination, by exterminating them in some suitable areas, usually exhibiting a high mortality, though expensive, would be justified." It is interesting to note that this is just what was done last summer in New York City by Dr. Donald B. Armstrong, of the Bureau of Public Health and Hygiene of the New York Association for Improving the Condition of the Poor, with results that are convincing, and Levy of Richmond, in an address as yet unpublished, states that he has reduced the mortality from infantile diarrhea in Richmond more than fifty per cent. by anti-fly work and great care to protect the diapers of sick children from flies. Armstrong's experiment, by the way, was accompanied by a rigid control.

With regard to cholera, he states that the evidence concerning its spread by flies is somewhat old, but is so remarkable that careful investigation is highly desirable.

Admitting that flies are greatly attracted to tuberculous sputum and can carry and distribute *Bacillus tuberculosis* for several days, he contends that whether they are serious factors in the spread of the disease remains to be proved.

Concerning the organisms of other bacterial diseases, especially ophthalmia, he states that these may be distributed by flies, but little definite evidence on the subject is available.

It is surely not the intention of Dr. Graham-Smith to underestimate the danger from flies, although his book read by the unscientific eye may produce this effect on the scientific mind. He closes with a strong plea for careful additional observations and investigations. For the elucidation of some of the problems, while expert knowledge is required, he states that accurate observations by workers without especial scientific training will be of the greatest assistance.

The book as a whole is an excellent one. I wish that the writer might have displayed more of the arguments against flies that are not founded upon definite bacteriological examinations; but there are other books that do that, and this one is a reliable one to have

on the desk to consult from time to time upon questions of exact fact. The interest in this line of investigation is so intense at present that it is perfectly obvious that enough new facts will be accumulated in another season to warrant the adding of several chapters.

L. O. HOWARD

The Progress of Scientific Chemistry in Our Own Times. By SIR WILLIAM A. TILDEN. New York, Longmans, Green and Co. 1913. Second edition. 15 × 20 cm. Pp. v + 366. Price, \$2.25 net.

The period covered by the book is from 1837 to the present. The first date was selected because Queen Victoria then came to the throne, while the scientific justification might be that at that time the influence of Liebig's teaching was beginning to be felt. After the usual preliminary chapter on Lavoisier, Cavendish, Dalton and Berzelius, we get to the book proper. We start with the conservation of energy and Joule's determination of the thermodynamic equivalent of heat. This leads at once to Hess's law of thermochemistry, to the experiments of Julius Thomsen, to Berthelot's enunciation of his principle of maximum work, and to St. Claire Deville's work on dissociation. The second chapter—which perhaps should have been the first—deals with the distribution of the chemical elements and the recognition of them by the chemist. This, of course, involves Bunsen and Kirchhoff's work on spectrum analysis, the discovery of argon by Rayleigh and Ramsay, and the isolation of the other noble gases by Ramsay. The elements being given, the third chapter deals with the determination of the atomic weights, including the theoretical reforms of Cannizzaro and the experimental researches of Dumas, Stas and others. The work of Gerhardt, Laurent and others on types is also taken up in this chapter. This seems a mistake because the work has to be discussed later in its proper place. The justification for its inclusion at this point seems to be that it was necessary in order to determine the atomic ratios of carbon to hydrogen and oxygen. While this is doubtless true historically,

it would have been more artistic to have passed over this difficulty gracefully and thus to have avoided repetition.

Once we have the atomic weights determined, we are confronted with Prout's hypothesis. The third edition will undoubtedly contain the account of the resurrection of this hypothesis by Rutherford, but only a prophet could have included that in this edition. After Prout's hypothesis has been disposed of, the remainder of the fourth chapter is devoted to Mendeléeff's periodic law and its developments. The question of constitutional formulas comes up in the fifth chapter, which carries us through the work of Kekulé. The fruitfulness of Kekulé's conception is brought to our minds clearly in the account of synthetical organic chemistry in the sixth chapter. In the seventh chapter we have Pasteur's work on optically active substances, and the theory of stereochemistry as developed by van't Hoff and Le Bel. The next step, historically and logically, is from the problem of the molecular structure to that of chemical affinity, and the eighth chapter is consequently devoted to a discussion of electricity and chemical affinity.

Up to this point, the treatment has been logical and coherent; but the ninth chapter is an intercalated one on the liquefaction of gases. There is no conceivable reason for introducing this chapter at this point except that the author perhaps did not know where else to put it. As a matter of fact it should have come in just before the account of Ramsay's isolation of the noble gases of the atmosphere. Presumably it was not put there because the author wished to discuss the liquefaction of helium, which he could not do until he had introduced helium to his audience. He should however have discussed the general problem of the liquefaction of gases as an introduction to Ramsay's work and he could then have taken up the liquefaction of helium as a special fact under the general properties of helium.

If this had been done, we should have passed directly from the chapter on chemical affinity to that on radioactivity. The loose ends are gathered up in a final chapter which includes

remarks on photochemistry, colloids and research work in Great Britain. Altogether this is a very readable book and all the more so because of the continuity of plan, which is quite unusual. Most writers of historical outlines content themselves—or are forced to content themselves—with isolated chapters. It is really quite a feat to have avoided this danger to so great an extent as Sir William Tilden has done.

The reviewer is entirely in sympathy with the contention, in the preface, that students should not only know the names of the leaders of scientific thought, but should perceive correctly the connection between their discoveries and the general progress of their science. In order to bring this about, a series of biographical notes has been appended to each chapter. In these notes are given a brief sketch of the life and work of every deceased chemist or physicist who has contributed substantially to the progress thus far accomplished.

WILDER D. BANCROFT

BOTANICAL NOTES

PROTOCOCCUS, NOT PLEUROCOCCLUS

In a recent number of *Nyt Magazin for Naturvidenskaberne* (Christiania) N. Wille gives the results of his studies of the actual specimens of certain lower green algae prepared by C. A. Agardh, and still preserved in the herbarium of the University of Lund, Sweden. One outcome of these is the settlement of the question as to whether or not the name *Protococcus* is still valid. As every teacher knows there has been a strong tide against the use of the name *Protococcus* for the common green slime of tree-trunks and walls, the preferred name being *Pleurococcus*. In the paper under consideration the author first gives a summary history of the nomenclatural tangle which has arisen. In 1824 C. A. Agardh named a certain plant *Protococcus viridis*. In 1842 J. Meneghini, not knowing Agardh's plants, proposed the name *Pleurococcus*, and included blue-green as well as green species, and among the latter he included the plants named *Protococcus viridis* by Agardh.

Other forms of confusion resulted from this initial blunder of Meneghini's but what is here given is sufficient to warrant Wille's conclusion:

It is clear that in order to disentangle such a confused mass of synonyms one must go back to the original specimens to determine what C. A. Agardh really understood by his species *Protococcus viridis*.

So he examined the original specimens and found that the specimens labeled *Protococcus viridis* are what later authors have called *Pleurococcus*. This fact requires, as Wille says, that "this species must therefore be called *Protococcus viridis*."

Since *Pleurococcus* was used by Meneghini for blue-green and also green algae that name is left badly discredited, and must doubtless fall into synonymy.

SHORT NOTES

SOME recent systematic papers are: A Consideration of Structure in Relation to Genera of Polyporaceae, by Doctor Adeline Ames (*Ann. Mycol.*, Vol. XI.), including a key to, and descriptions of sixteen genera, with four half-tone plates; New Fucaceae, by N. I. Gardner (Calif. Univ. Pub., Vol. 4), containing descriptions of some western rockweeds and their close allies, and accompanied by eighteen half-tone plates of excellent photographs of the plants described.

BULLETINS 284 and 285 of the Bureau of Plant Industry of the U. S. Department of Agriculture on the Water Requirement of Plant deal with some of the scientific facts that underlie the practical aspects of agriculture. In the first the joint authors, L. J. Briggs and H. L. Shantz, report in detail upon their investigations made at the dry-land experiment station at Akron, in northeastern Colorado, in the years 1910 and 1911. The bulletin is a valuable contribution to the physiology of the water loss sustained by plants under arid conditions. In the second bulletin the same authors have rendered a most welcome service to plant physiologists by presenting in summary form a review of the literature of the water requirement and water loss

of plants. These summaries are so systematically arranged that they must prove of the greatest help to plant physiologists.

ALLIED to the foregoing is Dr. F. J. Alway's paper, "Studies on the Relation of the Non-available Water of the Soil to the Hygroscopic Coefficient" (Research Bull. No. 3, Agr'l. Expt. Station of Nebraska).

AMONG the recent pathological papers are: M. T. Cook's Report of the Pathologist for the year 1912 (N. J. Expt. Station) enumerating especially the diseases of the year; Ethel Field's Fungous Diseases Liable to be Disseminated in Shipments of Sugar Cane (Circular 126; Bureau of Plant Industry, U. S. Dept. Agric.); Adeline Ames's New Wood-Destroying Fungus (*Bot. Gaz.*, May, 1913); P. J. O'Gara's Studies on the Water Core of Apples (*Phytopathology*, April, 1913), and Organization and Methods of Control of Plant Diseases (Wash. State Hort. Assn., 1913).

HERE may be mentioned H. R. Cox's paper, "Controlling Canada Thistles" (Farmer's Bulletin 545, U. S. Dept. Agr.), containing a good deal as to the biology of these weeds, as well as practical suggestions as to how they may be eradicated.

HERE too should be noted O. F. Cook's "Wild Wheat in Palestine" (Bull. 274, Bureau of Plant Industry, U. S. Dept. Agric.), describing "a new type of wheat growing in a wild state" in Palestine. Though this paper "does not attempt to reach a final decision on the question whether the wild wheat of Palestine is the true ancestor or prototype of the domesticated varieties of wheat," it does serve to bring out "several additional facts regarding the character and habits of the plants."

THE NEW VOLUME OF THE SYLLOGE FUNGORUM

QUITE recently the twenty-second volume of this work reached American subscribers. It is a continuation of the "Supplementum Universale" of the twenty-first volume, and includes the descriptions of added species of fungi to the end of the year 1910. Like the volume immediately preceding, it is the joint

work of P. A. Saccardo and Alex. Trotter. It is devoted to the Ascomycetaceae (pp. 1-822) and Deuteromycetaceae (pp. 823-1505). A Repertorium of 24 pages, an Alphabetical Index of species (69 pages), and an Index of Genera (13 pages) close the volume.

SPECIAL ARTICLES

THE SOLAR SPECTRUM AND THE EARTH'S CRUST

PROFESSOR ROWLAND's list of the elements whose lines appear in the solar spectrum has long been a classic work of reference among astronomers, and Dr. F. W. Clarke's summary of the chemical composition of the earth's crust occupies a similar position among geologists. Each list has been thoroughly discussed, by various writers, from the standpoint of the science to which it belongs; but little attention seems to have been called to the striking resemblances between the two.

In the annexed table are given (1) Rowland's list of the elements whose dark lines appear in the integrated spectrum of the sun, arranged in the order of the combined intensity of the lines of each element, as quoted in Abbot's "The Sun," p. 91 (1911); (2) a similar list of the elements, arranged in the order of the intensity of their bright lines in the spectrum of the solar atmosphere, as photographed at the total eclipse of 1905 by S. A. Mitchell¹; (3) Clarke's table of the percentage composition of the outer ten miles of the earth's substance, including the lithosphere, hydrosphere and atmosphere,² and (4) the average composition of ninety-nine stony meteorites, as derived by G. P. Merrill from published analyses.³

¹ *Astrophysical Journal*, 38, 407-495, and 39, 166-177, 1913-14.

² As given by him in Bulletin 491 of the U. S. Geological Survey, pp. 27-33, with additional data from papers in the *Proceedings of the American Philosophical Society*, Vol. 51, p. 220, 1912, and the *Journal of the Washington Academy of Sciences*, Vol. 4, pp. 59-62, 1914.

³ Quoted by Clarke on p. 39 of the work first cited.

Solar Spectrum, Dark Lines (Howland)	Chromosphere, Bright Lines (Mitchell)	Earth's Crust, Outer 10 Miles (Clarke)	Stony Meteorites (Merrill)
1 Ca	Fe	O 49.85%	O 35.75%
2 Fe	Ti	Si 26.03	Fe 24.52
3 H	H	Al 7.28	Si 18.20

34 Pb			
35 Er			
36 K			

All these lists are doubtless incomplete at the lower end. Later researches have shown that oxygen, gallium, ruthenium and all the rare earths given in Mitchell's list, should be added to Rowland's table, raising the number of elements represented to forty-five. The presence of nitrogen is also indicated by the appearance of the cyanogen bands, but not by its own lines. Photographs showing fainter lines would probably considerably extend the list of elements recognizable in the flash-spectrum. The list of elements in the earth's crust is certainly very incomplete below those which form 0.01 per cent. of the total. If carried out to the limit it should of course include all the elements, and it is not yet known what positions some of them, such as

the rare earths, would occupy in a complete scheme. The list for the stony meteorites is probably far from exhaustive, and it is not safe to draw conclusions from the failure of some elements to appear in it. It may be added that, according to Farrington,⁴ the average percentage of nickel in meteoric irons is about 7.5, and that of cobalt about one tenth as much, while that of copper averages about 0.02. It would therefore seem reasonable to suppose that the amounts of "Ni+Co" given in the table should be divided between the two metals in about this ratio.

Upon comparing the lists of Rowland and Clarke, we meet at once the fact—one of the commonplaces of astrophysics—that the non-metallic elements, with the exception of carbon and silicon, are scarcely if at all represented in the solar spectrum. The only one whose lines appear is oxygen—which is from 20 to 100 times more abundant in accessible materials than all the others put together (excepting C and Si, as above). If we simply accept this fact (which is still without adequate explanation), and exclude these non-metallic elements from the comparison, the similarity between the order of the remaining elements in the two lists is remarkable.

Of the eight metallic elements (including carbon and silicon under this head for the moment) which are most abundant in the earth's crust, six are among the eight whose lines are strongest in the solar spectrum, and one of the other two comes ninth in the solar list. Of the next eight metallic elements in the terrestrial list, seven are found among the second group of eight in the solar list, and the other one (Ni) is among the first eight. That is, fifteen of the sixteen leading metallic elements are common to the two lists, and there is a general similarity in their relative order in the two.

Beyond this point comparison becomes hardly practicable, as the terrestrial list is probably incomplete. Four of the next eight elements in Rowland's list are rare earths, for which there are as yet no sufficient analytical

⁴ Publications of the Field Columbian Museum, Geological Series, Vol. 3, No. 5, p. 110.

data. It is clear, however, that the elements whose lines are faint in the sun are, in general, present in but very small proportions in the earth's crust.

It is very remarkable that the correspondence of the two lists is so close, in view of the radical differences in the methods of investigation, and the great differences in the relative intensities of the lines in stellar spectra of different types. Even in the bright-line spectrum of the solar atmosphere, the similarity is by no means as pronounced.

Out of the first sixteen elements in either list, only one, barium, has an atomic weight exceeding 100, and but one other, strontium, one greater than 60. The significance of this fact has frequently been discussed by geologists or by astronomers.⁵ In both cases it has been suggested that the heavier elements lie for the most part deep within the body, and out of reach; but Clarke gives good reasons for believing that, even in the earth's interior, the lighter elements are more abundant than the heavier. This suggests that the faintness or absence of the lines of the heavier metals in the solar spectrum may be due largely to the small proportions in which they occur, and some confirmation of this is found in the fact that, of the elements of atomic weight greater than 180, only lead, which is the most abundant in the earth's crust, appears at all in the sun. But the rarity of these elements can not be the whole explanation of their absence from the solar spectrum, for although no lines of Os, Ir or Pt occur in it, the stronger lines of the equally rare elements Ru, Rh and Pd (whose atomic weights are about half as great) appear distinctly, though faintly.

The element which is most disproportionately conspicuous in the sun, in comparison with its terrestrial abundance, is cobalt. Nickel too is relatively high on the solar list. This may be partly explained by the great number of lines in the spectra of these elements, which gives them undue weight in a spectroscopic count. It is also worthy of notice that, if 25 per cent. of meteoric iron

were added to a sample of the earth's crust, and the composition of the resulting mixture considered, iron would occupy the first place among the metallic elements, nickel the eighth, and cobalt the eleventh, and the discordance with the solar list would disappear. Of the elements abundant in the earth, and relatively less conspicuous in the sun, silicon apparently approaches the typical non-metallic elements in its behavior, while aluminium has only four lines in the observable region, and is thus handicapped by the spectroscopic method of detection.

The principal differences in the order of the metallic elements in the two lists are therefore easily explicable, with one conspicuous exception. Potassium, which is one of the principal constituents of the earth's crust, and is fairly abundant in meteorites, shows as the merest trace, if at all, in the solar spectrum, although many strong lines, both of the principal and the subordinate series, lie in the observed region. Their absence, in spite of the presence of conspicuous lines of elements which are far less abundant in terrestrial materials, is remarkable, and would seem to demand some special explanation. It is of interest in this connection that potassium, alone among the more common elements, is slightly radio-active. If this indicates that its atoms are relatively unstable, they might break down under solar conditions; but this is a highly speculative consideration. The lines of the more strongly radio-active elements do not appear at all in the solar spectrum; but this may be accounted for by their extreme rarity (on earth, at least) and their high atomic weights. It should however be mentioned that lithium, which is next to potassium in abundance among the alkali metals, and occurs in sensible proportions in the earth's crust, but, so far as is known, is not radio-active, is also practically absent from the solar spectrum—though Adams⁶ points out that a very faint line, greatly strengthened in sun-spots, at wave-length 6708.08 may represent the strongest line in the lithium spectrum.

⁵ Compare Clarke, *op. cit.*, p. 33, and Abbot, "The Sun," pp. 92-94, 253-254.

⁶ *Astrophysical Journal*, Vol. 30, p. 92, 1909.

In spite of these exceptions, the agreement of the solar and terrestrial lists is such as to confirm very strongly Rowland's opinion that, if the earth's crust should be raised to the temperature of the sun's atmosphere, it would give a very similar absorption spectrum. A moderate admixture of meteoric material would make the similarity even closer.

In conclusion, the writer desires to express his very hearty thanks to Dr. Clarke, for valuable information on the geochemical side of the problem, and for the suggestion that the comparison here made (which has been given in the writer's lectures for several years) may contain enough that is unfamiliar to justify its publication.

HENRY NORRIS RUSSELL

PRINCETON UNIVERSITY OBSERVATORY,

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION K—PHYSIOLOGY AND EXPERIMENTAL MEDICINE

At 4:30 o'clock on the afternoon of Friday, January 2, 1914, Section K met at the Atlanta Medical College, Atlanta, Georgia, with Vice-president Theodore Hough in the chair. The address of the retiring Vice-president, Dr. John J. R. Macleod, entitled, "The Physiological Instruction of Medical Students," was read by title owing to the lateness of the hour.

The Section then began the symposium on the subject of pellagra. The first speaker, Dr. J. W. Babcock, superintendent of the State Hospital for the Insane, at Columbia, S. C., spoke on the "Medico-Legal Relations of Pellagra." Dr. Babcock has not sent to the secretary an abstract of his remarks.

Captain J. F. Siler, of the U. S. Army Medical Corps, Dr. P. E. Garrison, U. S. N., and Dr. W. J. MacNeal, assistant director of laboratories, New York Post-Graduate Medical School, presented a paper read by Dr. MacNeal entitled, "Further Studies of the Thompson-McFadden Commission on the Etiology of Pellagra." An abstract follows.

"The Entomological Aspects of the Pellagra Investigation of the Thompson-McFadden Commission" was presented by Mr. A. H. Jennings, of the Bureau of Entomology, U. S. Department of Agriculture, Washington, D. C.

Report of the Thompson-McFadden Pellagra Commission:

Information concerning the age and sex, occupations, location of domicile, general dietary habits and concerning the existence of pellagra was obtained upon about five thousand persons by a house-to-house canvass of six cotton-mill villages. A similar study was carried out in one rural district of four square miles in which several cases of pellagra had occurred. Many other communities were studied in less detail. There was no definite relation observed between the occurrence of pellagra and the use of any particular foods. New cases developed for the most part in the immediate vicinity of old cases or after close association with them. In districts completely equipped with water carriage systems of sewage disposal, we found pellagrins who had acquired the disease before moving to these districts. Cases apparently originating in these sewered districts were extremely rare and their origin there somewhat doubtful.

These observations strongly suggest that unsanitary methods of sewage disposal have an important relationship to the spread of pellagra. If these indications can be confirmed in other places, we feel that the proper correction of these conditions by the installation of water carriage systems of sewage disposal will go far toward restricting the spread of the disease.

The exact mode of transmission of pellagra is still uncertain and we strongly urge the continued study of food contamination, of insects as transmitting agents and of close personal association as possible factors in its spread.

Summary of Two Years' Study of Insects in Relation to Pellagra: ALLAN H. JENNINGS.

The results of a study by the writer and W. V. King, in cooperation with the Thompson-McFadden Pellagra Commission in Spartanburg county, S. C., are here summarized, the observations and conclusions referring to conditions in that region except where otherwise stated.

Infectiousness of the disease and its transmissibility by blood-sucking insects were assumed, purely as a necessary basis for our work.

A high percentage of female cases, especially among home-frequenting individuals and among children of both sexes is a marked characteristic of the disease, a transmitter which is active by day being thereby indicated.

The characteristics of the insects studied justify

the incrimination of the biting stable fly, *Stomoxys calcitrans*, alone. These characteristics and the species studied are given below.

The distribution of pellagra and its occurrence in persons seemingly not exposed to attack by lice, possibly, also, the sex incidence, are not satisfactorily explained by their incrimination.

Bed bugs, though abundant, fail to account for the sex incidence of pellagra, while the habits and scarcity of horse-flies exclude them.

The prevalent mosquitoes, *Culex quinquefasciatus* (= *fatigans*) are nocturnal in habit and the day-biting *Aedes calopus* is of irregular occurrence in the region.

The human flea, *Pulex irritans*, is rare or wanting in the county. Fleas of animals cause little annoyance and they do not explain the sex incidence.

Simulium species do not associate with man and pellagra sufferers are usually rarely exposed to their attack. They are negligible as a pest of man in the region. Pellagra occurs, also, in regions from which they are absent.

Sand flies (*Chironomidae*), if present, are not a pest in the region.

The stable fly is a practically cosmopolitan and abundant species; it associates with man, invades his dwellings and attacks him freely; it bites by day and its longevity is considerable. Human blood has been determined in the stomachs of an important percentage of individuals and human blood may be drawn without pain, in many instances.

If the cause of pellagra is an intestinal bacterium, the house fly may very probably be a vehicle for its diffusion.

The house-infesting roaches, in this event, may also play a minor part.

Discussion of Pellagra—Mental Disturbances: E. BATES BLOCK, M.D.

There is no one type of mental disturbance characteristic of pellagra. Insanity is usually a late manifestation of the disease and when it occurs it usually means that the end is near. As a terminal event it usually assumes the type of the infective exhaustive psychoses, with clouding of the consciousness, confusion, hallucinations and changing delusions, with marked restlessness and apprehensiveness.

When the insanity occurs earlier in the disease before the exhaustion becomes marked, it is usually characterized by great depression with delusions which are depressive or persecutory in character. This is associated with marked apathy or restlessness

and general nervousness and insomnia, and sometimes with excruciating headaches. Mental confusion is quite common; apprehensiveness is often a marked feature of the disease. Suicidal attempts are quite common, but in only one of the cases which I have seen has there been any violence towards others.

Sometimes the insanity precedes the physical signs of pellagra as a part of the disease. While insanity does not confer immunity to pellagra and the sequence may have been accidental, I have seen several cases which have developed insanity suddenly and were so shortly followed by symptoms of acute pellagra that I believed them to be a part of the same disease. One of these was apparently typically psychasthenia, another melancholia, while a third was apparently manic depressive insanity, but all were quickly followed by the typical signs of pellagra. The prognosis in these cases is much more favorable than in the cases in which the insanity developed as a late manifestation of the disease. Occasionally the apathy is so great as to suggest dementia præcox and the cases of this type that I have seen have run a very chronic and protracted course.

The development of insanity is not necessarily of fatal significance. In one of my cases the patient has remained perfectly well now for eight years and in another for five years, without any recurrence either of mental or physical symptoms.

The prognosis of pellagra was discussed by Dr. George M. Niles, of Atlanta, Ga., as follows:

My experience in the treatment of over six hundred cases of this malady has made me somewhat optimistic, and I feel that the attitude of extreme pessimism assumed by some observers is unjustified.

Pellagra, like some other diseases, seems more virulent when implanted on virgin soil. We note that in the Old World, where it has been rife for nearly two centuries, the mortality is not near so great. In this country it is in many respects a new enemy, and its prospective victims have not been able to establish, as it were, any form of immunity against its ravages.

In my professional intercourses with pellagrins and their inquiring friends I have adopted a classification as to the conditions in which a favorable outcome may be anticipated, or the reverse. There are four classes in whom I am extremely chary in holding out a favorable prognosis: First, pellagrins over fifty or fifty-five years of age. The pathologic changes of this disease closely simulate those of senility, and when to the changes

due to weight of years are added like burdens due to disease, Nature can not hope to successfully contend with both. Second, confirmed alcoholics. These unfortunates seldom recover from pellagra. Third, cases in which the mentality is seriously impaired. These psychic changes indicate marked destruction of important nerve centers, and render the prognosis doubtful. Fourth, that class of intellectual weaklings who have neither the intelligence nor pertinacity to faithfully hold to and observe a course of treatment for months or years, if necessary, but who are continually shifting from one to another, or taking the nostrums of quacks and charlatans. Practically all of this fourth class succumb.

On the other hand, those who are not included in the classes just mentioned, who will zealously and patiently carry out the medicinal, dietetic and hygienic rules of those physicians who are experienced in the care of such cases, the hope of ultimate and permanent recovery may be confidently grasped by the large majority.

Let me in closing admonish my hearers that the keynote in the treatment of pellagra is *optimism*. If the patient can be kept in good spirits, and in a consistently hopeful frame of mind, the higher centers, untrammelled by fears or obsessions, can best exert their beneficent influence over the lower centers, vegetative and otherwise, and with a brighter hope of victory can we combat this dreaded scourge.

L. O. HOWARD,
Secretary pro tem.

THE AMERICAN PHYSICAL SOCIETY

A REGULAR meeting of the Physical Society was held at the Bureau of Standards, Washington, April 24 and 25, 1914. This was a joint meeting with the electrophysics committee of the American Institution of Electrical Engineers. The programs of the two morning and of the Saturday afternoon sessions were in charge of the Physical Society with President Merritt in the chair. The Friday evening session was in charge of the A. I. E. E. with Chairman J. B. Whitehead in the chair. The Friday afternoon session was given to a lecture by Sir Ernest Rutherford, F.R.S., of the University of Manchester, Eng., "On X-ray and Gamma-ray Spectra," complimentary to the American Physical Society.

Special features of the meeting were the opening of the new electrical building of the Bureau of Standards and an exhibit of physical apparatus. This exhibit was arranged under the direc-

tion of a committee of the American Physical Society with Dr. F. A. Wolff as chairman. It was a large and representative exhibit, participated in by thirty-two manufacturers, importers and industrial research laboratories, ten universities and educational institutions, and eight federal scientific bureaus.

Members of the Physical Society were especially invited by the National Academy of Sciences to attend the William Ellery Hale lectures by Sir Ernest Rutherford, F.R.S., upon "The Constitution of Matter and the Evolution of the Elements." These were given in the auditorium of the National Museum on April 21 and 23, and were attended by a large number of the Physical Society members.

All in attendance at the meetings were the guests of the scientific staff of the Bureau of Standards at luncheon on both days of the meeting. After the Friday evening session the local branch of the A. I. E. E. gave a smoker which was largely attended.

At a short business session of the Physical Society the following items of business were transacted:

On recommendation of the council, it was voted to establish a new grade of foreign members, to be defined as non-residents of North America, to pay dues of \$4.00, with no initiation fee and to receive the *Physical Review* (with *Science Abstracts* on additional payment of \$2.00) and having all rights of regular members in the society. Also, to make such changes in the by-laws as the establishment of this new grade of membership would necessitate.

On motion it was voted to approve and authorize an International Congress of Physics to be held in Washington in October, 1915, in case it should appear that it can be properly financed. (A committee of nine was appointed by the Council to determine this question).

It was voted that the president appoint a committee of three to express the deep sense of loss felt by the members of this society in the death of their former president, Professor B. O. Peirce.

The society voted to express to the director and members of the National Bureau of Standards its high appreciation of the generous hospitality extended to the society throughout the meeting, also to the Washington Section of the American Institute of Electrical Engineers for arranging trips and providing guides to various places of scientific interest in the city and its neighborhood.

The program of scientific papers was as follows: "Solenoids," by C. R. Underhill.

"Some Investigations of Lightning Protection for Buildings," by DeBlois.

"A Milli-Ampere Current Transformer," by Edw. Bennett.

"Some Simple Examples of Transmission Line Surges," by W. S. Franklin. (By title.)

"Theory of the Corona," by Bergen Davis.

"High Temperature Measurements with the Stefan-Boltzmann Law," by C. E. Mendenhall and W. E. Forsythe.

"Cold-end Compensator for Thermocouples," by Charles B. Thwing. (Apparatus shown.)

"The Emissivity of Metals and Oxides. I; Nickel Oxide (NiO) in the Range 600° to 1,300° C.," by G. K. Burgess and P. D. Foote.

"Formulae for the Ordinary Mercury Contact Thermostat, and Some Practical Conclusions Deduced from Them," by W. P. White. (By title.)

"The Specific Heats of Mixtures of Water and Alcohol, and of Solutions of Non-Electrolytes in these Mixtures," by W. F. Magie.

"The Extension of the Spectrum in the Extreme Ultra-Violet," by Theodore Lyman.

"The Infra-red Arc Spectrum of Barium," by H. M. Randall.

"On the Growth and Decay of Color Sensation," by M. Luckiesh.

"Some Effects of Diffraction on Brightness Measurements made with the Holborn-Kurlbaum Optical Pyrometer," by A. G. Worthing and W. E. Forsythe.

"Further Experiments on the Use of the Photo-electric Cell in Stellar Photometry," by Jakob Kunz, J. Stebbins and W. F. Schulz.

"Displacement of Arc Lines not Due to Pressure," by Chas. E. St. John and H. D. Babcock.

"On the Accuracy of Terrestrial-magnetic Measurements," by L. A. Bauer.

"The Gamma-ray Comparison of Specimens of Radium Salts," by N. Ernest Dorsey.

"Note on the Photo-electric Effect with Potassium Surfaces in Very High Vacuum," by Saul Dushman.

"The Results of the Atmospheric Electric Observations on the Second Cruise of the *Carnegie*, June, 1910, to December, 1913," by C. W. Hewlett.

"Apparatus for the Spectroscopic Synthesis of Color," by H. E. Ives and E. J. Brady.

"New Methods for Measuring Time Constants of Low Resistances," by Frank Wenner, Ernest Weibel and F. B. Silsbee.

"A Sensitive Moving Coil Galvanometer," by F. Wenner, E. Weibel and F. C. Weaver.

"Some Records of the Wireless Time Signals Made with a Physiological Recorder," by C. W. Waggoner.

"Electric Conduction and Thermo-electric Action in Metals," by E. H. Hall.

"Electrochemical Indicators and Recorders. Instruments for Showing Continuously the Chemical Content of Solutions," by F. A. Harvey.

"Characteristic Curves of Tungsten Filament Incandescent Lamps and their Application in Heterochromatic Precision Photometry," by G. W. Middlekauff and J. F. Skogland.

"The Thomson E.M.F. in and the Thermal Conductivity of Tungsten in Incandescent Temperatures," by A. G. Worthing.

"A Direct Determination of h ," by R. A. Millikan.

"Some Peculiarities in the Thermal Expansion of Invar," by Arthur W. Gray.

"A New Turbidimeter," by P. V. Wells.

"The Diurnal System of Convection," by Wm. H. Blair.

"The Control of the Wave-length Sensibility Curves for Selenium," by E. O. Dieterich.

"On the Relation between the Photo-electric Potential and the Frequency of Light for Potassium," by S. Karrer.

"Reflection and Scattering of Slow-moving Electrons," by Albert W. Hull.

"Reversible Transitions between Solids at High Pressures," by P. W. Bridgman.

"Surface Leakage over Insulators," by H. L. Curtis.

"Spark Potentials in a Magnetic Field," by R. F. Earhart. (By title.)

"Some Points with Regard to the Variation of the Specific Magnetization of a Substance with Temperature," by W. F. G. Swann.

"High Frequency Verification of Kirchoff's Capacity Formulae," by F. C. Blake and Chas. Sheard. (By title.)

"Corona Produced by Continuous Potentials," by S. P. Farwell.

"A Significant Instance of Galvanometer Instability," by W. P. White.

"Wave-length Sensibility Curves of Potassium Photo-electric Cells," by H. E. Ives.

"An Electromagnetic Puzzle," by F. J. Rogers.

"The Photo-electric Effect of Carbon as Influenced by its Absorbed Gases," by Otto Stuhlmann, Jr., and R. J. Piersol.

"The Relation of Residual Gases to the Photo-electric Sensitiveness and the Contact E.M.F. of Sodium," by R. A. Millikan and W. H. Souder.

"Effect of Glass Walls on Thermionic Currents," by Saul Dushman.

"A New Design of Flicker Photometer for Laboratory Colored-light Photometry," by H. E. Ives and E. J. Brady.

"Note on the Physiological Effect of the Current," by F. J. Rogers.

"Examples of the Precision Attainable in Determinations of Thermal Expansivity," by Arthur W. Gray.

"Dioptric Formulæ for Combined Cylindrical Lenses at Oblique Axes," by Charles Sheard. (By title.)

"The Testing of Potentiometers," by Frank Wenner and Ernest Weibel.

"An Absorbing Solution for Eliminating Color Differences in Photometry," by H. E. Ives and E. F. Kingsbury.

"Photographs of Retrograde Rays, (a) from the Cold Cathode, (b) from the Hot Lime Cathode," by O. H. Smith.

THURSDAY, JANUARY 1, 1914

Systematic Bacteriology

Morphology of the Bacteria (Vibrio and Spirillum), An Early Research: JOSEPH LEIDY, JR.

This paper will be published in SCIENCE.

The Classification Card and the Type or Study which it Merits: H. A. HARDING.

The classification card has not appealed to the pathologists, because they could test unknown cultures more quickly on animals, nor to water bacteriologists because their attention has been focused upon *B. coli* and special media, but it has been very valuable to students of bacterial ecology. The card is justly criticized because the observations of bacterial cultures are not always accurately recorded by it and because the present group number is unwieldy and of undetermined value as a basis for classification. One of the most urgent demands of bacteriology to-day is the careful testing out of various suggestions looking toward an improved technique. Dr. H. J. Conn has suggested that the ease of handling the group number can be increased by pointing it off into periods of about three figures each. The significance of such periods would be increased if each was devoted to a class of reactions such as morphology, fermenta-

tion, nitrogen relations and enzymes. The reactions should be selected for this group number after careful study of their accuracy and utility, and pending the results of this study the card of 1907 should be retained practically unchanged.

Constancy in the Fermentative Activity of Streptococci: JEAN BROADHURST.

Attempts to correlate the fermentative results of different workers in saccharose mannit and other Gordon media have led to a series of experiments dealing with the different conditions characterizing the technique in different laboratories. Differences, such as acidity, presence or absence of sugars, subjection to raw and variously heated milks, were tried out without finding any definite results on the later Gordon reactions. Slight and brief increases in temperature (above 37°) depressed fermentative activity decidedly. Much more marked (as previously reported) were the contrasts resulting from the use of meat extract and of meat Gordon media. These effects are evidently not necessarily lasting. Permanent changes were effected by a stay in the alimentary canal (*e. g.*, a gain in lactose in dogs fed on streptococci-free milk). Cultures kept for 1 to 4 months on meat agar (10-day transfers) showed a gain in the amount of fermentative activity (the amount of acid), many strains show also a gain in the number of substances fermented; less often a loss occurred in the number of substances fermented. Studies carried on with individual animals for varying periods (2-10 mo.) showed unexpectedly wide ranges in the physiological types of mouth and fecal streptococci, affecting probably the diagnostic value of fermentative reactions. These, and other phases of the work reported upon, seem to warrant the following conclusions: (1) Constancy may be claimed for streptococci under identical or duplicate conditions. (2) Constancy in these fermentative responses is also characteristic of a large percentage of strains, under varying or varied conditions. Age, a stay in the alimentary canal, and meat extract, have more effect on such results than any of the (19) varied conditions tried.

The Relation of Habitat and Physiological Characters in the Streptococci: L. A. ROGERS AND ARNOLD DAHLBERG.

It is reasonable to assume that true species in the bacteria will be found associated with a definite habitat as it is with the higher plants and animals. Studies were made of the physiological characters of 51 cultures from infected udders; 114 cultures from bovine feces; 31 cultures from

the mouths of cows and 42 cultures from milk obtained by selecting cultures showing chains in lactose bile at 37°. The morphology varied under different conditions but the udder cultures showed the most uniform and consistent chain formation. The cultures from the several sources differed in the amount of acid formed in dextrose broth, those from the mouth giving the highest acidity and those from the udder the lowest. The milk cultures were slightly higher than those from the udder. The udder cultures would be divided into two distinct groups, one of which fermented dextrose, saccharose and lactose and occasionally mannite and agreed with the published descriptions of strep. pyogenes. The second group frequently liquefied gelatin and in addition to dextrose, saccharose and lactose, usually fermented the alcohols mannite and glycerine. The cultures from feces were particularly uniform in their reactions, fermenting dextrose, saccharose, lactose and raffinose and frequently the polysaccharides starch and inulin, but failing to ferment the alcohols or liquefy gelatin. The cultures from the mouth differed from those from the udder in the higher percentages of raffinose, inulin and mannite fermenters and in less action on glycerine and gelatin. They are sharply differentiated from the feces organisms in their general failure to ferment starch and in the much higher percentage of mannite fermenters. Two of the milk cultures evidently belong with the feces group. All others may be placed in one of the two udder groups.

The Significant Characters of the Colon Group Isolated from Cow Feces: L. A. ROGERS, WM. M. CLARK AND ALICE C. EVANS.

Previous work on a collection of the colon type from milk demonstrated that the gas ratio and volume are constant under uniform conditions; that, on the basis of the gas ratio and volume, the cultures may be divided into two distinct groups and that the correlation of the fermentative ability with the gas ratio makes this distinction sharply defined.

This paper records the results of a similar study on 150 cultures isolated from bovine feces. None of these cultures liquefied gelatin and all but one found indol from tryptophane. By the use of a simple medium and exact methods of analysis it was found that in 149 cultures the $\text{CO}_2:\text{H}_2$ ratio varied from 0.98 to 1.20 only. One culture only gave a ratio identifying it with the high ratio group which made up 48 per cent. of the milk series. The 149 low ratio (0.98-1.20) cultures

were readily divided into two groups, one of which fermented dextrose, saccharose, lactose, raffinose, mannite, glycerine and dulcite, but almost invariably failed to ferment starch, inulin and adonite, while the second group ferments dextrose, lactose, mannite and glycerine, occasionally ferments adonite and dulcite and fails to ferment saccharose, raffinose, starch and inulin.

These groups agree almost perfectly with two groups which may be formed from the low-ratio cultures isolated from milk. Special methods failed to give evidence, with the exception of the single culture mentioned, of the presence in bovine feces of the high ratio group which made up about one half of the milk collection.

Studies on the Classification of the Colon Group:
I. J. KLIGLER.

Eighty organisms generally classed under the colon group were subjected to a series of fermentative and other tests with a view of determining their natural grouping as based on biometric principles. The following tests were employed: (1) Morphology, Gram. (2) Fermentation of dextrose, lactose, saccharose, raffinose, glycerine, mannite, dulcite, salicin and inulin. (3) Coagulation of milk. (4) Liquefaction of gelatin. (5) Production of indol. (6) Reduction of nitrates. (7) V. & P. reaction. Fifty-seven of the strains fell into the lactose fermenting division; twenty did not ferment lactose but fermented dextrose; three failed to ferment.

Acid production as determined by titrating aliquot portions of the broth with phenolphthalein as an indicator was found to be a more constant and a more reliable differential test than gas production, as ordinarily determined. The degree of initial acidity had no appreciable effect on the final acidity, which was quite constant, reaching its maximum on about the fourth day. The fifty-seven lactose fermenters attacked mannite, glycerine, saccharose, salicin raffinose, dulcite and inulin in the order named. Mannite, raffinose and inulin were found to be of minor or doubtful classificatory importance. Saccharose divides the lactose group into two distinct subgroups.

On subdividing the saccharose groups on the basis of dulcite and salicin fermentation respectively, it was found that the saccharose-salicin groups gave better correlations with indol production, V. & P. reaction and gelatin liquefaction, than did the saccharose-dulcite groups.

The saccharose positive, salicin positive group corresponds to *B. aerogenes*.

The saccharose positive, salicin negative group corresponds to *B. communior*.

The saccharose negative salicin positive group corresponds to *B. communis*.

The saccharose negative salicin negative group corresponds to *B. acidilactici*.

Glycerine was found to be of value in separating the cloacae forms from the aerogenes bacilli, 78 per cent. of the saccharose positive, salicin positive, glycerine negative strains being liquefiers.

It must be kept in mind, of course, that this classification was obtained with a relatively small number of organisms and can at best be considered only tentative. The results are, however, sufficiently interesting to merit further investigation, especially on the part of those interested in the bacteriology of water. Of the dextrose positive lactose negative forms five liquefied gelatine and fermented dextrose and saccharose but failed to ferment any of the other sugars, with the exception of glycerine, which was fermented by two of the organisms. Of the other tests, all were negative with the exception of indol, which was negative for the two glycerine positive organisms and positive for the glycerine negative. For the present all the five may be grouped under the name *B. vulgaris*. The sixty-two members of the colon group discussed may, therefore, be said to fall into six main species as follows:

Species	Specific Tests	No. of Organisms
<i>B. communior</i>	dex. +, lac. +, sac. +, sal. —	12.
<i>B. communis</i>	..dex. +, lac. +, sac. —, sal. +	11.
<i>B. aerogenes</i>	..dex. +, lac. +, sac. +, sal. +	19.
<i>B. acidilactici</i>	..dex. +, lac. +, sac. —, sal. —	6.
<i>B. cloacæ</i>	...dex. +, lac. +, sac. +, sal. +, glyc. —	9.
<i>B. vulgaris</i>	...dex. +, lac. —, sac. +, gel. +	5.

A Biochemical Study of Proteins with Reference to the Behavior of Bacteria towards Pure Animal and Vegetable Proteins: JOEL A. SPERRY, 2p.

Solutions of unchanged egg albumin, serum albumin and edestin were carefully prepared. To these solutions sodium chloride, sodium sulphate, calcium chloride and potassium phosphate were added. The composition of these solutions was then of such a character that the bacteria were obliged to break down the protein molecule in order to obtain the necessary nitrogen to synthesize their food in the presence of the inorganic salts. The two most important factors in this investiga-

tion are: first, that the protein used is really a normal or unchanged protein, and second, that there must be nothing in the final solution from which the organism might obtain the necessary nitrogen, except the native protein. The organisms used in this investigation were *B. subtilis*, *B. prodigiosus*, *B. anthracis*, *B. proteus vulgaris* (two different strains), *B. proteus mirabilis*, *B. coli*, *B. typhi*, *B. pyocyaneus*, *Bacillus "Z,"* a proteus-like organism isolated from the feces of white rats fed on experimental protein diets, and the anaerobes, *B. putrificus*, *B. anthracis symptomatici*, and *B. edematis maligni*.

Test tubes containing about 10 c.c. of the protein solutions were inoculated from 24-hour slant agar cultures. In making the inoculations every precaution was observed to avoid transferring any of the medium to the tubes containing the protein solutions. Plates were poured immediately after inoculation, and at intervals of 24, 48, 96 hours, and one week; in a few instances ten days and two weeks. The amount of the inoculated material used in the plates was 0.5 c.c. of a 1:10,000 dilution. The plates were incubated at suitable temperatures and the number of colonies counted 24 to 48 hours later. The period of time during which the organisms survived after being planted in the protein solutions, as shown by the examination of the plates, varied from 48 hours to 10 days. None of the inoculated material gave any visible evidence of decomposition or even putrefaction. Flasks containing 25 c.c. of the different protein solutions were inoculated with various organisms and incubated at the optimum temperature for the organism under observation, for a period of two weeks. At the end of this time tests were made to determine the quantity of coagulable protein. The amount of coagulable protein in the inoculated flasks and the control flasks remained the same, showing clearly that there was no appreciable loss of protein.

A Study of the Bacteria Concerned in the Production of the Characteristic Flavor in Cheese of the Cheddar Type: ALICE C. EVANS AND E. G. HASTINGS.

A comparative study of the flora of raw- and pasteurized-milk cheese of the Cheddar type has been made, with reference, particularly, to the production of characteristic flavors. The raw-milk cheese flora was found to consist of the following four groups of cheese organisms: *Bact. lactis acidii*, *Bact. casei*, *Streptococci* and *Micrococci*. Several varieties of each group occur in

the cheese, according to the classification as determined by the fermentation in broth containing carbohydrates or related substances. The flora of pasteurized-milk cheese is shown to depend upon the organisms introduced in the starter, with the exception of the *Bact. casei* group, which develops slowly and is concerned with the production of the biting flavor in mature cheese.

Many experimental pasteurized-milk cheeses were made with starters consisting of the organisms isolated from normal raw-milk cheese, either in pure culture or in varying combinations. The results of these experiments showed that pronounced differences in the flavor could be brought about by varying the cultures in the starter. Certain combinations in the starter resulted in an improvement of the flavor.

Technic

The Application of Practical Records to the Maintenance of Stock Bacterial Cultures: L. T. CLARK AND W. L. DODD. (By invitation.)

The scope of a bacterial culture bureau has been gradually broadened, as new organisms have been isolated requiring additional tests to differentiate between old and new species. To assist in their classification a practical system of records is a necessity and to this end the writers submit a method which has had three years' application. Essentially it consists of a double system of records: one, a card index, consisting of classification charts which provide for the morphological, cultural and biochemical characteristics as well as space for the name, age, source and number of the organisms in question. The auxiliary system is a book record of the cultures in numerical rotation.

To avoid confusion resulting from maintaining cultures on the shelves in numerical sequence, an arrangement in groups according to biochemical, morphological and cultural characteristics has been found convenient. Protection from light and dust is provided by means of the black boxes described by Novy. The variable requirements of organisms make it necessary to transplant them at intervals ranging from three weeks to a week or less. Growth of stock anaerobes is established in a volume of pure hydrogen gas. Most pathogenic types may be grown for the first twenty-four hours at incubator temperature, after which they are easily maintained at ordinary room temperature. Saprophytic cultures are kept continuously at room temperature. A duplicate set of cultures is maintained at a low temperature.

The following advantages may be claimed for

the system as outlined: The history of the culture forms a part of the record and is readily available; the cultures are easily handled and transplanted; any one of the organisms may be easily and quickly located by its number, name or by some predominant biologic characteristic.

The arrangement in groups, of cultures of similar characteristics, facilitates a further and more complete classification. This leads to the detection of variations between strains of the same species.

A Study of the "Tellurite Reaction" with the Colon-typhoid Group and other Organisms: LEWIS DAVIS.

The writer has investigated the reaction of potassium tellurite with the more important members of the colon-typhoid group and allied organisms, with the view of determining:

(a) Differences in antiseptic action on the various members of the group; (b) variations in the macroscopical appearance, character and velocity of the "tellurite reaction" under optimum conditions; (c) the influence of treatment with tellurite on the biochemical activities of the organism.

The bacteria studied included the following, arranged in the order of their resistance to the antiseptic action of potassium tellurite: *B. capsulatus mucosus*, *B. capsulatus*, *B. coli communis*, *Bact. (lactis) aerogenes*, *B. cloacæ*, *B. proteus vulgaris*, *B. paratyphosus "B," B. of swine plague*, *B. enteritidis*, *B. typhosus*, *B. paratyphosus "A," B. paracoloni*, *B. acidi lactici*, *B. cholerae suis*, *B. rhinoscleromatis*, *B. pneumoniae*, *Bact. dysenteriae (Shiga)*, *B. icteroides*, *Bact. dysenteriae (Flexner)* and *B. zopfii*. The variations in resistance to potassium tellurite, as well as in the appearance of their reaction with this salt, are considered sufficient to suggest the use of the tellurite for differential diagnosis within the colon-typhoid group.

The intensity of bacterial action on potassium tellurite was found to depend upon the individual resistance of the bacterium and the concentration of the salt present. The velocity of reduction of the tellurite is considered to be a specific function of an organism apart from its resistance to antiseptic action. Most of the types studied showed a reaction within thirty minutes. With the colon bacillus the reaction was almost instantaneous. Comparison was made of the action of "tellurited" and normal bacteria with dextrose, lactose and saccharose bouillons, respectively, as well

as with litmus milk. Treatment with potassium tellurite was found to have practically no influence on the biochemical reactions of an organism.

An Improved Technique for Performing the Grüber-Widal Test for Typhoid Fever: F. M. MEADER, M.D.

The method herewith described is not new in its elements, but the combination is one which I have not noticed in other laboratories that I have visited or in the literature. We have been using the method in the city laboratory of Syracuse for three months now with considerable satisfaction. A description of the method is herewith offered.

Apparatus.—There are used the following materials: 1st, a vial with straight sides, 2 cm. long and having a 0.5 cm. lumen. The cork stopper has fixed into the inner surface a lance. (A) 2d, a standard wire loop made from a No. 25 U. S. gauge platinum wire, the lumen of which is 2 mm. in diameter. (B) 3d, a capillary pipette with perforated nipple, graduated in two places to deliver the equivalent of 3 and 4 standard loopfuls of serum. (C) 4th, a mixture tray having a dozen or more cells such as is used by artists for mixing paints. (D) 5th, a hanging drop slide. (E) 6th, cover slips. (F) 7th, alboline oil. 8th, sterile salt solution, 9th, a 24-hour bouillon culture of *B. typhosus*.

Procedure.—Prepare a control by placing a loopful of salt solution upon a coverslip. Then mix with it a loopful of the culture of *B. typhosus*. Place a ring of alboline oil around the depression in the cover glass. Invert the coverslip over the depression in the slide so that the center of the drop comes over the middle of the depression. Examine under the microscope to see that the culture is active and that the organisms are sufficiently numerous. If the preparation is satisfactory, the time is noted and it is set aside for one hour.

Given a sample of blood in vial A. If the vial is about one fourth full of blood, and is then centrifugized, there will be a satisfactory amount of serum present. With the graduated pipette measure 4 loopfuls of salt solution into one of the cells of the mixing tray. Then measure 3 loopfuls of salt solution into another cell of the mixing tray. With the standard loop take one loopful of the serum and mix it with the salt solution first measured out. This makes the dilution of serum 1-5. Transfer a loopful of this mixture to the second solution measured out. This makes a dilution of 1-20. Transfer a loopful of this mixture

to a coverslip. Add to it a loopful of the culture of *Bacillus typhosus*. This makes a dilution of 1-40. Prepare a hanging-drop slide as above with oil. Invert the coverslip over the depression and examine under microscope. Note the time and examine one hour later for agglutination.

The particular point of value in this technique is the use of the capillary pipette. Since there is a perforation in the nipple, the salt solution will rise to the graduations by capillary force, so that an exact amount of diluent can be easily and accurately obtained. The liquid can be pushed out into the cell of the diluting tray by covering the perforation with the finger and compressing the bulb. Since the viscosity of serum is greater than that of salt solution, the volume of a loopful of serum will be greater than the loopful of salt solution. So that in calibrating the pipette 3 and 4 loopfuls of serum should be used instead of salt solution in order that in practise the volumes of diluent and serum will be comparable. The method commends itself for its simplicity, rapidity of operation and precision in measurement.

A Synthetic Medium for the Determination of Colon Bacilli in Ice Cream: S. HENRY AYERS AND WILLIAM T. JOHNSON, JR.

In a study of the bacteria in ice cream we have endeavored to prepare a synthetic medium for the detection of colon bacilli. During the experiments 53 different combinations were tried. The most satisfactory medium was made as follows: Agar, 1.5 per cent.; asparagin, 0.3 per cent.; sodium dibasic phosphate, 0.1 per cent.; lactose, 1.0 per cent., and 2 per cent. of a saturated solution of litmus. The majority of the bacteria in ice cream did not grow on this medium, while colon bacilli showed quite characteristic acid colonies which with a little practise could be readily detected. The colon count on litmus lactose asparagin agar was compared with the estimated number from lactose bile tubes in 43 samples of ice cream. In 41 of the 43 samples the number determined on the plates was higher than the estimated number from the bile tubes.

Suspected colon colonies on the asparagin plates from 19 samples were picked off and inoculated into lactose broth fermentation tubes. From ten plates all the suspected colonies, or 100 per cent., proved to be gas formers. Among the other nine plates the percentages ranged from 87.17 per cent. to 98.01 per cent. This shows that it is possible to detect quite accurately any colonies of gas-forming bacteria on litmus lactose asparagin agar.

A comparison of this medium with Endo medium showed that the colon count on asparagin agar was much lower than that on the other medium. We found, however, that in some cases at least it was impossible to consider all typical colonies on Endo plates as colon bacilli. Certain strains of *B. coli* failed to give typical colonies on Endo plates and acid and peptonizing bacteria gave reactions similar to some of the colon strains.

It is evident that we have no entirely satisfactory method for the determination of colon bacilli, but it is believed that the use of synthetic media may be developed to a point where it will be superior to other methods.

A Satisfactory Platinum Needle: L. A. ROGERS.

The tendency of platinum needles set in glass handles to break when they are flamed, is a source of annoyance. A needle which will avoid this trouble may be made by fusing the platinum wire into a copper wire. This may be done by twisting a bit of small wire about the platinum wire and holding in the flame of a blast lamp until it forms a ball at the end of the wire. The copper ball and the end of a copper wire of the proper size are held together in the flame until they fuse. The rough joint obtained may be hammered or filed to approximately the diameter of the copper wire, which should be large enough to insure rigidity. The wire may be mounted in a capillary tube or in an ordinary glass tube with plaster of Paris. The needle may be thoroughly flamed without danger of breaking.

Immunity

On the Value of a New Skin Test for Diagnosis of Tuberculosis: DR. J. BRONFENBRENNER.

In the work reported to this society last year by Dr. Manwaring and myself¹ and subsequently continued and published in the *Journal of Experimental Medicine*,² it was shown that tuberculous guinea-pigs acquire the power of reducing the number of tubercle bacilli injected into their peritoneal cavity; that certain fixed cells of the peritoneal cavity were apparently responsible for this phenomenon, as even removed from the body of the guinea-pig the isolated peritoneal tissues of tuberculous animals had the power of reducing the number of tubercle bacilli placed in contact with them; that, however, as far as our experiments went the

intraperitoneal destruction of tubercle bacilli in tuberculous animals was not caused by circulating antibody. It was thought, however, worth while to investigate what changes the blood of these guinea-pigs underwent in the conditions of the experiment, as it seemed improbable that the cells of the peritoneal cavity could have acquired immune properties without these being present in the blood. A series of experiments was undertaken to test complement deviation on the blood of tuberculous animals, but the results obtained varied with the different strains of tubercle bacillus used as antigen. In general, however, experiments showed that the blood of guinea-pigs often contains specific antibody against tuberculous antigen. Having established this fact, an attempt was made to see if this antibody is of the nature of a bacteriolysin. The series of experiments were performed both in vitro and in vivo. In the course of this last series of experiments a very interesting phenomenon was noticed, namely: that if a normal guinea-pig was injected intraperitoneally with a mixture of the serum of a tuberculous guinea-pig with the peritoneal exudate resulting from the injection of a small amount (10,000) of tubercle bacilli in the peritoneal cavity of another highly immunized guinea-pig, often a local reaction would result on the spot of inoculation, followed by a rise of temperature. This local reaction was especially pronounced in the cases where the peritoneal wall was punctured several times for the purpose of removing a sample of the exudate, and in this way probably a part of the mixture was introduced from within the peritoneal cavity under the skin of the animal. In analyzing this phenomenon it was found that the peritoneal exudate employed in these experiments could be conveniently replaced by a crude tuberculin as prepared by the Board of Health of New York, but not very well by a suspension of washed tubercle bacilli. The non-washed (possibly partly autolyzed) suspension of tubercle bacilli, especially if not freshly prepared, could also be used successfully. Since then, a number of tests were performed in which guinea-pig serum was replaced by the serum of tuberculous patients, and it was found that the reaction, although not very constant, is of a prognostic value in tuberculosis.

While the work is still in progress, the experiments performed up to date seem to show that the complement is an important factor in the phenomenon, inasmuch as heated sera failed to give this reaction, yet if activated by the addition of a complement and left at room temperature for a

¹ *Centrbl. f. Bact. Ref.*, Bd. 59, No. 12, p. 371.

² *Jour. of Exp. Med.*, 1913, Vol. XVIII, No. 6, p. 601.

short time, they could be reactivated. Whether the reaction is due to the liberation of an anaphylatoxin from the mixture of the serum containing the toxogenin and complement with the antigen of the tuberculin, is a question to be decided in the experiments which are to follow. At present I wish to call attention to this phenomenon as a possible method for the diagnosis of tuberculosis at least in cases where the condition is not too far advanced and where there is some of the free antibody in the circulating blood.

Subcutaneous injection 0.55 c.c. of a mixture of fresh blood of patients suffering from tuberculosis (1 c.c.) with tuberculin (crude diluted 1 to 10 0.1 c.c.) into a normal guinea-pig causes a local reaction similar in its aspect to a tuberculin reaction which is of good prognostic value in diagnosis of tuberculosis.

The Relationship of Anaphylaxis to Immunity:

FRASER B. GURD.

The experiments reported in this paper were undertaken in the hope of procuring data which might throw light upon the fact, now well established, that in order that an animal may become "immune" to a complex proteid, such as serum albumin, it is necessary that the animal first become, potentially at least, anaphylactic.

The author believes that there is not sufficient evidence upon which to base the theory of sessile and free receptors, as suggested by Friedberger and recently actively championed by Weil. That the reaction of the body to the parenteral introduction of foreign proteins is an exhibition of the property of parenteral digestion, is well established, as indicated by the work of Alberhalden, Zunz, Friedberger and others. That at one stage in the process of protein cleavage a highly poisonous split product is produced, is also proven, and that it is on account of the elaboration of ferments or lysins, capable of producing cleavage of the injected protein with the liberation of this toxic product, that the anaphylactic state is developed, appears sufficiently well supported by numerous experiments. The author desires to suggest that the immunity to or tolerance of heterologous protein introduction is due to the tissues of the repeatedly injected animal acquiring the property of elaborating a second order of lysins which are potent to produce more complete cleavage of the toxic split-protein products. Thus it is due to the presence in the body fluids and tissues of two orders of lysins, that the "immune" animal is itself protected against the harmful effects of pro-

tein injection, even though its serum is potent to passively sensitize normal animals.

The author's experiments prove that it is possible, by varying the quantity of transferred serum injected, to render normal animals either highly sensitive or "immune." Thus, two guinea-pigs which received (intravenously) .6 c.c. of serum from an immune rabbit were found to be sensitive (at the end of 24 hours), to 5 and 6 minims of sheep's serum, the latter with a fatal termination; whereas a rabbit which received 4.0 and 4.5 c.c. of the same rabbit serum on two successive days, and 24 hours later was injected with 7 minims of sheep's serum, was found to be immune.

In another series of experiments the toxic injections were carried out immediately following the injection (intravenous) of the transferred serum. In these experiments it was found that whereas 0.5 c.c. of rabbit's serum rendered a normal pig highly anaphylactic (dyspnea and convulsions), the injection of 2.75 c.c. was sufficient to induce a complete tolerance to the toxic injection of the protein.

Study of the Bacteriology of the Posterior Nasopharynx in Scarlatina: N. S. FERRY, M.D.

The study of the bacteriology of the posterior nasopharynx in scarlatina was undertaken by the writer to isolate, if possible and determine the rôle of a certain micrococcus found in this region and briefly described by Dr. Schultze in a preliminary report in the *Medical Record*, New York, December 10, 1910. This organism was seen by Dr. Schultze in smears from 459 out of 555 cultures taken from the throats of patients suffering with typical symptoms of the disease. The greatest number of positive findings have been obtained by swabbing the posterior pharyngeal wall and allowing the swab to stand in a test tube of bouillon a few hours. The entire amount of bouillon is then plated in the usual manner. The organism was not isolated in the later stages of the disease and was not found in any of the purulent discharges nor the blood, which seems very significant considering the fact that it appears to coincide with the contention of the majority of observers that the disease is contagious only in its early stages. For convenience in nomenclature this organism was called by the writer Micrococcus "S" and, for the present, it will continue to be designated by that term.

The Mic. "S" is a large coccus usually found in pairs and often tetrads which grows luxuriantly on all culture media after the first few generations. Whether the Mic. "S" has or has not any spe-

cific clinical or pathological significance, for the purpose of placing it on record, a detailed description of the organism will be given, followed by a brief review of the experimental work carried out with it.

Morphology.—Mic. "S" is a large, clearly defined, biscuit-shaped diplococcus, sometimes appearing in tetrads, measuring about the size of the meningococcus and gonococcus. It is non-spore-bearing, non-motile, non-capsulated, stains deeply with all aniline dyes and is positive to Gram.

Cultural Reactions

Agar Slant.—Abundant, smooth, grayish-white, glistening, opaque, filiform or slightly beaded raised growth, becoming somewhat viscid within a few days.

Agar Deep.—Abundant, filiform, growth usually in one plane, with a slightly spreading surface growth.

Agar Colony.—Slow-growing, round, smooth, convex, entire, coarsely granular colony.

Bouillon.—Slight growth, clear with sediment.

Potato.—Very slight, colorless growth.

Litmus Milk.—No change.

Koch's Serum.—Slight, filiform, white growth.

Loeffler's Serum.—Abundant, filiform, smooth, glistening, pinkish white growth.

Gelatin Stab.—Gradual stratiform liquefaction. In about five days a cup forms at the surface and as liquefaction increases it reaches the sides of the tube and then proceeds downwards. At the end of six weeks, the medium is liquefied about half way down.

Indol negative.

Litmus Sugars.—Glucose, maltose and saccharose gave an acid reaction; galactose, levulose and lactose, no change.

Pathogenic Powers

While extensive inoculation experiments were carried out with this organism, nothing of any special specific significance could be gleaned from the work. Whether the organism soon loses its virulence on artificial culture media, or whether it is devoid of all pathogenic properties for the animals used, is a question which was undecided. Believing, nevertheless, that this organism was found in a large enough proportion of cases to warrant further work, irrespective of the apparently negative pathogenicity, several vaccines were prepared with it which have been fairly tested out, both prophylactically and therapeutically under the supervision of Dr. Schultze in New York and Dr. Kiefer in Detroit, which work will be reported in later communications by them.

Other observers have, from time to time, noted the presence of a large diplococcus in cultures and smears from the throats of scarlatina cases, and

yet no one has succeeded in proving that it has any part to play in the disease and, therefore, very little stress has been laid on the findings. The organism described by these writers is so varied in its morphology and cultural characteristics that one is inclined to one of two suppositions. Either it is extremely polymorphous, as was claimed by Class, or else they were dealing with cultures containing streptococci, which organisms may often be seen, in smears from the throat directly or from cultures, as large diplococci.

From the experience of the writer with the organism he has isolated and named Mic. "S," which tallies with the general descriptions given by Schultze, Class and others, as seen in smears it is quite essential not only to plate the cultures, but to be absolutely certain that the colonies from which the cultures are taken have no small colonies of streptococci, either deep or superficial, adjacent to or near them. This can only be ascertained by examining the field with a lens. Among the several known organisms found in the throat, from which the Mic. "S" should be differentiated, the following are the most important.

Mic. catarrhalis.

Mic. tetragenus.

Mic. pharyngis sicus.

Dip. intracellularis meningitidis.

Studies in Avian Tuberculosis: L. R. HIMMELBERGER.

Cultures of the avian tubercle bacilli were grown on sterile banana and glycerinated slants of carrots, turnips and garden beets. The different character of the growths obtained on the different media, would suggest the use of these vegetables as differentiating media. Attempts were made to infect white rats, under conditions simulating cohabitation with tuberculous chickens and guinea-pigs and rabbits by injection of pure cultures subcutaneously and intravenously (in rabbits) without success. Two calves were infected by the ingestion of mascerated tubercular organs of chickens while in one an attempt at infection by ingestion was unsuccessful. The calves were tuberculin tested previous to infection and came from a cow which had given no actions to the tuberculin test, and were fed from a herd free from tuberculosis as indicated by repeated tuberculin tests. The calves which were infected gave reactions to tuberculin prepared from the avian organisms and on autopsy lesions of tuberculosis were found. It is regrettable that we were not able to isolate this organism. The agglutination test was tried on a limited number of birds both normal and diseased. In only

one case did a normal bird (as shown by macroscopic examination at autopsy) exhibit an agglutination titre over 1:50 and this bird had been subjected to infection. All of the birds showing lesions on post-mortem examination gave a titre as high as 1:100.

JANUARY 2, 1914

Pathology

A Comparative Study of the Intestinal Flora of White Rats Kept on Experimental and on Ordinary Mixed Diets: LEO F. RETTGER AND GEORGE D. HORTON.

The investigation extended over a period of almost one year, and was carried on in connection with the pure protein nutrition experiments of Osborne and Mendel. The feces of 22 rats were examined, 17 of the rats receiving the experimental diets consisting essentially of purified animal or vegetable protein, protein-free milk, starch and lard. The remaining 5 rats received ordinary mixed food consisting of sunflower seeds, carrots, dog-bread, meat, etc.

A change in the intestinal flora became apparent very soon after the rats were transferred from the ordinary to the special diets. The flora became more simplified, very few types being found after the first three or four days, as a rule. An increase in the number of Gram-positive organisms from 35-50 per cent. to 85-100 per cent. was frequently observed. There was no appreciable difference in the results, in so far as the individual proteins were concerned, with the exception of Zein. Although they were present in the feces of the stock-room rats in relatively large numbers, two organisms which are a part of, or closely related to, the acidophilus group of bacteria, were frequently present to the exclusion of all other types, except *Bacillus bifidus* of Tissier and *B. coli*, *B. bifidus* was much more abundant in the experimental rats than in those receiving the usual diet, while the number of *B. coli* was greatly reduced. No definite relationship could be established between the bodily conditions (growth, vigor, etc.) of the rats receiving the special diets, and the intestinal flora.

Anaerobic Culture of Coccidioides Immitis: WARD J. MACNEAL AND RICHARD M. TAYLOR, M.D.

Two strains of *Coccidioides immitis* of Rixford and Gilchrist³ have been studied, one derived from a fatal case of generalized infection which occurred

³ Rixford, Emmet, and Gilchrist, T. C., "Two Cases of Protozoan (Coccidioid) Infection of the Skin and Other Organs," Johns Hopkins Hospital Reports, 1896, Vol. I, p. 209-290.

in the practise of Dr. Chas. A. Powers, of Denver, and which has been studied by Whitman,⁴ and a second isolated at this laboratory⁵ from a similar case which occurred in the practise of Dr. Robt. T. Morris, of New York. We observed the metamorphosis of the spherical (Coccidioid) bodies into typical mycelial growth on agar and the inverse change of the threads back into spherical bodies in the animal body. Finally by inoculating the spherical bodies into tubes of ascitic fluid containing bits of sterile animal tissue, or better, tubes of gelatinized horse serum, and covering these with paraffin oil or incubating in an atmosphere of hydrogen, we succeeded in obtaining abundant multiplication of the spherical form *in vitro*. The forms of the organism in these cultures resemble very closely those seen in diseased tissues.

Further Observations of the Thompson-McFadden Pellagra Commission upon the Etiology of Pellagra: J. F. SILER, P. E. GARRISON AND W. J. MACNEAL.

Information concerning the age and sex, occupations, location of domicile, general dietary habits, and concerning the existence of pellagra was obtained upon about five thousand persons by a house-to-house canvass of six cotton-mill villages. A similar study was carried out in one rural district of four square miles in which several cases of pellagra had occurred. Many other communities were studied in less detail. There was no definite relation observed between the occurrence of pellagra and the use of any particular foods. New cases developed for the most part in the immediate vicinity of old cases or after close association with them. In districts completely equipped with water-carriage systems of sewage disposal, we found pellagrins who had acquired the disease before moving to these districts. Cases apparently originating in these sewered districts were extremely rare and their origin there somewhat doubtful. These observations strongly suggest that unsanitary methods of sewage disposal have an important relationship to the spread of pellagra. If these indications can be confirmed in other places, we feel that the proper correction of these conditions by the installation of water-carriage systems of sew-

⁴ Whitman, R. C., "A Contribution to the Botany of the Organism of Blastomycosis," *Jour. of Infectious Diseases*, July, 1913, Vol. XIII., pp. 85-95.

⁵ MacNeal, W. J., and Hjelm, C. E., "Note on a Mold, *Coccidioides immitis*, Found in a Case of Generalized Infection in Man," *Jour. Amer. Med. Assoc.*, December 6, 1913, Vol. LXI., No. 23, p. 2044.

age disposal will go far toward restricting the spread of the disease. The exact mode of transmission of pellagra is still uncertain and we strongly urge the continued study of food contamination, of insects as transmitting agents and of close personal association as possible factors in its spread.

Further Studies with Reference to Spirochæta suis:

WALTER E. KING, RAYMOND H. DRAKE AND G. L. HOFFMAN.

This report gives in detail the results of the study of the flora of the crypts in the ceca, intestinal ulcers and the external local lesions of a number of normal, immune and diseased hogs, with reference to the presence of *Spirochæta suis*. The study includes the examination of 234 cases by means of the dark field. Of these, positive findings have been made in 171 cases, negative findings in 63 cases. Of the latter, 38 cases were hogs immune to cholera, 2 were animals susceptible but not exposed to hog cholera, 3 with typical hog cholera but treated with toxic doses of mercuric or arsenical preparations, 16 in which the organism was found either in local lesions or in the crypts and ulcers of the intestines, and 6 cases resulting in negative control findings. In 5 hogs which were made immune to cholera, *Spirochæta suis* was found in the crypts of their ceca at intervals of from 10 days to 11 weeks after exposure.

These data, together with results already reported, warrant the tentative deduction of the following conclusions: (1) In the ulcerated areas of cecal mucosa and in the crypts, near the ileo-cecal valve, of hogs dead from cholera, is localized a constant species of spirochete, *Spirochæta suis*. Experimental evidence shows that this organism is pathogenic for swine and that it plays an important part in the production of hog cholera. (2) The crypts in the ceca of activity immunized hogs may sometimes contain *Spirochæta suis* for a variable period of time after immunization. (3) *Spirochæta suis* becomes localized in the necrotic tissue or purulent exudate of the external lesions, which are sometimes present in cases of typical hog cholera, especially of the subacute chronic types.

The Relation of Lavatory Appliances to the Spread of Intestinal Infections: B. R. RICKARDS AND L. B. CLORE.

These experiments were carried out to determine the rôle played by the chain pull and other appliances of the toilet room in transmitting from hand to hand typhoid bacilli and other organisms capable of causing intestinal disorders. The surfaces tested were rubbed with sterile cotton swabs

previously moistened with sterile water. Plates made by rubbing the swabs over the surface of Endos medium in Petri dishes. The plates were incubated for 48 hours at 37° C. and inoculations into plain broth were then made from a number of each of the various kinds of colonies found, attention being centered on those cultures having a typical *Bacillus coli* appearance. The work was confined entirely to the detection of the colon group, lack of time preventing experiments being carried on for the presence of *B. ærogenes capsulatus*. The broth cultures were examined microscopically after 48 hours' incubation and transplants made into Hiss's semi-solid media. These tests were carried out on media containing, respectively, dextrose, lactose, saccharose and mannit. Typical growth on all four media was taken to mean that the organism isolated was a member of the typhoid-colon group.

In each instance swabs were taken from the front of the seat, back of the seat, door knob and from the handle of the device operating the flushing tank. From the low flush tank type, cultures were made from the metal or porcelain lever. If, of the high box type, the swab inoculation was made from the metal or porcelain handle and oftentimes from the lower parts of the chain, the object of the latter being to see if there was any attempt by the users of the closets to avoid infection by putting the hands on that part of the apparatus not commonly used. For the same reason swabs were in all cases taken from portions of the door with which the hand might come in contact in case the handle of the door was avoided.

B. coli was isolated in pure culture from swabs taken from the following locations. (1) From the seat in two different toilets of the scientific department of the manufacturing establishment. In one case tests were made at three different times and *B. coli* found each time. (2) From four different seats in the public comfort station. In no case was *B. coli* detected on the handles of pull or push levers nor on the chains, nor was this organism detected on the metal or porcelain door handles or upon the wood of the door.

While the results by experiments fail to show presence of *B. coli* on any other surfaces except on the wooden seat, we still feel that there is a possibility that the handles of flushing devices may at times serve as a means of carrying typhoid or other intestinal infection or possibly gonorrhea or syphilis from hand to hand, at short intervals and that foot or automatic levers should take their places.

The Malarial Parasites: MARY R. LAWSON, M.D.

Many of the misconceptions in regard to the morphology and biology of the malarial parasites are due to the fact that the majority of observers have believed them to be intracellular, and that each parasite grew up and completed its life cycle within a single corpuscle, the segmentation of the parasite corresponding to the final destruction of the corpuscle. The writer believes the parasites to be extracellular throughout their existence, that is, when not in migration, they attach themselves to the external surface of the red corpuscles by means of protoplasmic pseudopodia surrounding mounds of corpuscular substance, which the parasite has "squeezed up" for the purpose of attachment. This interpretation is confirmed by seeing the corpuscular mounds at the periphery of the red corpuscles encircled by the pseudopodia of the parasites.

The evidence in favor of migration is:

1. The destruction of red corpuscles is usually out of all proportion to the number of parasites present, providing one parasite destroys but one corpuscle.
2. In multiple infection of red corpuscles by several young parasites, they can not all grow up on one corpuscle, therefore they must migrate or die.
3. Stages of parasitic migration such as (a) Free pigmented parasites, compact, ameboid, with pseudopodia. (b) Pigmented parasites attached to apparently healthy corpuscles. (c) Pigmented parasites (24 hr.) apparently in the act of abandoning degenerated corpuscles. (d) Parasites on corpuscular skeletons. (e) Corpuscular skeletons which are expanded remnants of red corpuscles which have been dehemoglobinized.

The sexual cycle takes place in the blood of man in the various malarial infections. The flagella are always derived from the chromatin substance, and from the chromatin alone. In the æstivo-autumnal infections the writer has observed but one flagellum to each crescent, while in the tertian and quartan infections, there are several flagella to each parasite.

A Preliminary Communication on the Etiology of Pyæmia Arthritis in Foals: FRANK W. SCHOFIELD.

The author after a brief discussion relative to modes of infections points out that intrauterine infection of foal can alone account for some cases, and most probably does for more than is generally believed. The bacteriology of the disease is reviewed and author's findings given. An organism of the colon typhoid group has been recovered uncontaminated from blood and joints in early stages of disease. The relationship of this organism to

the disease was established by complement fixation tests using foals' blood and organism isolated as antigen. Positive fixation tests were also obtained from the blood of dams that have delivered foals which subsequently became diseased.

Experiments Bearing on Pulmonary Infection:

FRANK W. SCHOFIELD.

Mention is made of two existing views regarding pulmonary infection. That it is due to direct inhalation of course into smaller air passages, or arises as the result of a primary infection of blood stream. The difficulty of infecting the lung by direct inhalation was demonstrated by experiments of following nature.

First Experiment.—Horses were exposed to a very fine spray from powder atomizer, the material used being equal parts gentian violet and powdered charcoal. After a few minutes' spraying the atmosphere became saturated with this fine violet powder. Horses breathing normally filtered all the powder out of the inspired air before same reached trachea. When excessive, labored and rapid breathing was induced the powder could be detected in the larger bronchi.

Second Series of Experiments.—A spray of *B. prodigiosus* was here substituted for the powder. The spray was manipulated so that the fine terminal portion of the same enveloped the nostrils of animals breathing it. The spray was kept up for several minutes. In most cases the organism could not be recovered past the larynx. When present in the trachea bacilli were few in numbers. The last experiment consisted of taking a number of swabs from the trachea of normal horses, cattle, sheep. In most cases the tracheæ were found to be sterile. When the organ was infected the organisms were *S. aureus*, *S. albus* and *Streptococci*. None of the common organisms present in the air these animals were breathing were recovered from the trachea.

Conclusions.—In health the trachea if not sterile has no constant bacterial flora. This could not be so if dust with bacteria could easily pass the nasopharynx.

That with nasal breathing most of the bacteria inhaled are removed before the air enters the trachea, even when the atmosphere is saturated with bacteria.

That direct infection of lung through nasal inspiration is almost impossible, under ordinary conditions.

Secretary

"THE CAMERA OF QUALITY"

POLYGON CAMERAS

with

Rietzschel Double Anastigmats

are the embodiment of all that is desirable in cameras. They are compact, small, and light in weight, yet they are very reasonable in price: "They fit the Pocket." They are made from miniature size up to 5 x 7 inches, in all styles. All are built of light but indestructible metal; all are leather covered; all have leather bellows; all have rising, falling and cross front; all have detachable lensboard; all have quickly reversible ground glass; all are fitted with double anastigmats, the better ones with the finest cemented lenses ever put on the market, in compound shutter.

We also sell

ERNEMANN Cameras and Double Anastigmats

THE Moscow Natural Eye Model

Pat. Feb. 3, 1914.

A New and Valuable Aid in Teaching Anatomy and Physiology of the Eye

These models consist of a real, natural eye which has been hardened and fixed; then sectioned in half and mounted in a glass cell so as to show all the internal parts of the eye ball. These structures are all held in their normal positions, and may be easily identified by means of the diagrammatic cut, keyed to model, which accompanies each one.

"The Moscow Natural Eye Models are excellent preparations: We find them to be a great help in laboratory work in Zoology, Physiology, Anatomy, etc., etc." Dr. J. E. Wodsedalek, Professor of Zoology, University of Idaho.

Mounted in ebonized box with hinged cover, which protects the glass cell from injury. Absolutely permanent, and fully guaranteed.

Crile & Lower's Anoci-Association

Anoci-association is the *prevention* of postoperative shock—not its treatment. Anoci-association robs surgery of its harshness, diminishes postoperative mortality, lessens post-operative complications (shock, nausea, vomiting, gas pains, backache, nephritis, pneumonia, etc.). You get here, first of all, a monograph on *shock*—its kinetic theory, its histologic and clinical pathology, and its treatment. Then follow chapters on the principles of *anoci-association*; the technic of its application in the administration of the anesthetic in abdominal operations (gall-bladder, gastric, intestinal operations, herniotomy, perineal operations, abdominal infections, appendicitis, pelvic infections); in gynecologic operations (tumors, suspension of uterus, pus tubes), in genito-urinary work (bladder, kidney, prostate); in operations for cancer of the breast, rectum, stomach, uterus, larynx, and tongue; in exophthalmic goiter operations; in operations on the brain and the extremities (amputations, osteotomy, accidents). Then come chapters on *anoci-association* and *blood-pressure*, the relation to postoperative morbidity and mortality, and the technic of nitrous-oxid-oxygen anesthesia with details for equipping a hospital plant for the manufacture of nitrous oxid.

Octavo of 175 pages, illustrated. By GEORGE W. CRILE, M.D., F.R.C.S., Professor of Surgery, and WILLIAM E. LOWER, M.D., Assistant Professor of Genito-Urinary Surgery, Western Reserve University.

Allen's Local Anesthesia

This is a complete work on this subject. You get the history of local anesthesia, a chapter on nerves and sensation, giving particular attention to *pain*—what it is and its psychic control. Then comes a chapter on osmosis and diffusion. Each local anesthetic is taken up in detail, giving very special attention to *cocain* and *novocain*, pointing out the action on the nervous system, the value of adrenalin, paralysis caused by cocain anesthesia, control of toxicity. You get Crile's method of administering adrenalin and salt solution. The exact way to produce the intradermal wheal, to pinch the flesh for the insertion of the needle—all shown you step by step. You get full discussions of paraneural, intraneural, and spinal analgesia, intravenous and intra-arterial anesthesia, and Hackenbuck's regional anesthesia by circumferential injections. You get indications, contraindications, an article on *anoci-association*, with Crile's technic for producing anesthesia. Then the production of local anesthesia in the various regions is taken up in detail, abdominal work covers 50 pages, genito-urinary work and hernia another 50 pages. You get local anesthesia for rectal surgery, gynecologic operations and cesarean section. Spinal analgesia and epidural injections are considered in a monograph of 45 pages. There is a large section on *dental anesthesia*.

Octavo of 625 pages, illustrated. By CARROLL W. ALLEN, M.D., Instructor in Clinical Surgery at Tulane University of Louisiana.

IDEALS RELATING TO SCIENTIFIC RESEARCH¹

ONE object of this society, according to its constitution, is to establish "fraternal relations among investigators in the scientific centers." These relations imply changes in ideals as the body of the investigators grows and as its members take higher and higher views as regards social obligations. Our rapid scientific development in recent years may be compared with the great strides in our financial development. It has frequently been necessary during this period to enact laws with a view towards higher financial ideals and more just financial relations. Practises which appeared tolerable when indulged in on a small scale became intolerable when their influences began to extend to wider circles.

Hence it seems natural to inquire whether our rapid scientific development has not been attended by practises which appear more and more objectionable. It is also of some interest to look into the future with a view to learning whether some of our scholarly practises, which do not meet with open disapproval at present, are likely to become intolerable when our scientific life has become much more vigorous and when our universities have become much larger and more influential. At any rate, the investigator likes to look at facts from a variety of different angles, and he realizes the need of considering also surrounding atmospheric conditions.

Ideal research is free search. On the other hand, fraternal relations imply fraternal obligations. The great army of in-

¹ MSS. Intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

¹ Read before the Illinois chapter of the Society of the Sigma Xi, May 20, 1914.

investigators is composed mainly of generals. Only a few are willing to serve in any other capacity after announcing by means of a doctor's degree or by some scientific publication that they have learned to walk alone. It is true that many of them were supported by the kindly hand of their teacher during this first walking exhibition and some of these never learn to walk alone; but, nevertheless, they too often want to be generals or nothing in the army of the investigators.

The difficulty of learning to walk alone as an investigator seems to vary very much with the different sciences. In mathematics, for instance, the man who has just reached his doctor's degree in an American or in a German university can not be expected to have completely acquired this art,² while some of the newer sciences seem to present the strange phenomenon of babies born with walking capabilities. These wide differences may be expected to diminish with the more extensive scientific developments and with the growth of fraternal relations between investigators.

The question arises whether the independence of the separate investigators is an ideal condition and whether this condition should be maintained in view of the rapid increase of the number of investigators. Our scientific army seems to have adopted Indian war tactics to the extent that each man is selecting his own tree and is firing at the cohorts of ignorance from his sheltered position. In a new and undeveloped country this may be proper and may lead to the best results, but it is at least conceivable that as time goes on the army of scientists has to be reorganized along different lines in order to secure the most effective work. The Committee of One Hundred on Scientific Research recently appointed by the American Association for the Advancement of Science may be a step towards such a general reorganization.

² Cf. M. Bôcher, *SCIENCE*, Vol. 38 (1913), p. 546.

In some of the sciences special reorganization has already been started. By way of illustration we need only to refer to the recent work of the *Astronomische Gesellschaft*, which, by international cooperation, secured accurate observations of the positions of one hundred and sixty-six thousand stars. Such organizations tend to limit, along certain lines, the independence of the investigator, and hence they affect our ideals, at least as regards some investigators. It remains, however, still true that ideal conditions for an investigator involve a large measure of freedom, just as the most effective higher teaching implies opportunities to digress from beaten paths.

Probably most of the effective scientific investigation is a result of the fact that some student has taken the time to digress from the beaten paths at various points, and finally he came into regions of unexpected fertility. Love of knowledge, not love of renown, is the ideal incentive for investigation. The ideal investigator is not the man who says to himself "I am going to become an investigator" but rather the man who becomes deeply interested in a subject and is unable to find in the literature the things he is anxious to know. He is thus forced by a desire for more knowledge to become an investigator.

In some subjects there is a type of investigators who have been forced by a kind of laziness to become investigators. I refer here to the student who finds it easier to sit and think than to get up and consult the literature. In fact, some people have gotten into the thinking habit so thoroughly that it appears generally easier for them to think than to do even as much manual labor as to pick up a book and read. Investigators of this type have sometimes developed into comparatively ignorant men with great reputations, and some of them have done very much to advance knowledge.

It does not appear likely that this class of investigators will occupy a prominent place in the future. It is only about 150 years ago that Frederick the Great asked Lambert, as a new member of the Berlin Academy, what science he understood especially well, and he received the reply "all of them." Frederick the Great then asked how he secured all this knowledge, and Lambert answered "by myself like the noted Pascal."³ While these answers could scarcely be justified at the time of the founding of the Berlin academy, they would be much less appropriate in our day, and there is an ever-increasing need of using the results of others in research. Fortunately the means of arriving at these results are also improving. While the investigator becomes continually more dependent upon others he has the advantage of securing, by means of known results, a much wider freedom as regards fruitful subjects exposed to investigation.

In recent years the term graft has received a large amount of public attention. This is probably partly due to a rapid change in our ideals as regards political and financial standards. Our ideals as regards scholarly standards are also changing very rapidly, and it appears natural to inquire whether the term *scholarly graft* is not destined to receive more public attention unless some of our university practises are changed.

The fact that scholarly practises frequently improve with more light has been emphasized recently by results from the publications of the Carnegie Foundation for the Advancement of Teaching, as well as from the publication of a classification of educational institutions on the part of the U. S. Bureau of Education. Many other similar efforts have recently been made. One of the most important of these,

³ *Jahresbericht der deutschen Mathematiker-Vereinigung*, Vol. 23 (1914), p. 1.

as far as scientific subjects are concerned, is the work entitled "American Men of Science." It is a hopeful sign that such works have become possible. Naturally some institutions, as well as some men, have not welcomed this type of light, and slight injustices could scarcely have been avoided.

The history of the system of the honorarium in European universities furnishes many instances of injustice, and emphasizes the fact that even in good universities there is danger as regards the development of graft. The German universities have been very conservative as regards changes along this line, but in 1897 it was decided that one half of the honorarium over 3,000 Marks (in Berlin over 4,500 Marks), should, in general, be paid into the state treasury. In April, 1909, it was decided that the professors outside of Berlin were to receive, as before, all of the honorarium up to 3,000 Marks; but, if the total honorarium exceeded this amount, 75 per cent. of the sum between 3,000 Marks and 4,000 Marks, and only half of that beyond 4,000 Marks, was to be paid to the professors.

Two of the most serious charges against the practise of paying all of the honorarium to the professors were that it tended to influence some of the most noted men to give the most elementary lectures in the popular subjects, and that some professors who happened to be on the commission of examiners were tempted to make it very uncomfortable for the students who had not taken the courses offered by these professors. At any rate the system led to very great inequalities in the incomes of different professors and it was the source of many suspicions on the part of students and others.

Our American universities have thus far been comparatively free from gross scholarly graft, but it seems desirable to look at ourselves at times in a critical spirit in order to check tendencies which might

otherwise develop into gross irregularities. High ideals as regards public actions are not likely to prevail in a society where the discussion of public practises is in disfavor, since fear of exposure is one of the most useful instruments to regulate public practises.

One of the most common university practises which is at least closely related to graft is inefficient teaching. Too many of us neglect our obligations to our students. These obligations include a vigorous scholarly development on the part of the teacher. In the cases where an instructor gives graduate courses these obligations also include a vigorous growth in research ability, but they are not confined to such development and growth. This is, however, the side to which we shall pay most attention on this occasion.

Probably one reason why many of us do not consider more seriously our obligations to our students is based on the fact that there has been a rapid improvement during recent years as regards the teaching duties of the American university instructor. Too many of us have not learnt to use our freedom as rapidly as it has come to us. When an instructor has been oppressed with fifteen or twenty hours of instruction per week, in addition to directing graduate work, and finds this yoke of oppression gradually lifted, he does not always assume promptly the new obligations which this freedom implies.

It is, however, important for the younger members of our profession, and especially for those who are just now entering our ranks, to realize that holding a university position unworthily is a kind of scholarly graft which might perhaps be known as the incompetency graft. It seems very likely that with the improvement of conditions there will come higher ideals, and that in the future a higher degree of efficiency will

be demanded than could reasonably have been demanded in the past.

A kind of scholarly graft which is still too common is connected with the assignment of subjects for graduate theses. Some instructors, on meeting a problem which involves an unusual amount of drudgery, seem to regard it as legitimate to lay such a problem aside until they can find a student who will take it as a thesis subject. There is no surer way to kill all research ambition on the part of the student, nor is there a surer way to secure his permanent disrespect for the teacher and the subject.

It is simply another expression of the ignoble spirit which leads some men to regard the young and helpless as their legitimate prey. The teacher who does not do his best to find attractive and far reaching theses subjects for his graduate students is certainly not ideally qualified for a position in the graduate school. The use of graduate students to promote the interest of the teacher is simply a type of scholarly graft which we may call the promoter graft. Moreover, it is one of the most despicable types in existence in view of the fact that it affects those who have not yet formed strong scholarly habits.

The promoter graft presents itself in many other forms. One of the most common of these is an undue emphasis on the work done by the teacher himself. What is still more pernicious is to offer courses mainly with a view to learning a subject or with a view to writing a paper on a particular subject. It is difficult to prescribe proper limits along these lines. Research enthusiasm can generally be conveyed to students most effectively by the man who is himself profoundly interested in his subject, and who knows exactly how far the subject has been developed. Work along the border line between the known and the unknown has the greatest fascination, espe-

cially for the young man who never before experienced the joy of knowing beautiful and general results which have never been published.

It is, however, essential that these new results should be both beautiful and general in comparison with the many elegant things which have been found out by others. The great danger is that an instructor will find mainly non-interesting and trivial results in comparison with the many important known results which his students have not yet mastered. In view of the great differences in research capacities of university professors it is very difficult to give limits as regards the amount of original work which may properly be incorporated into our graduate courses.

All of us could doubtless point to clear instances where students have suffered greatly on account of injustice along this line. The extreme cases of the promoter graft are almost as vicious as the extreme cases of the incompetency graft. In many instances the former are the more difficult to correct since a large amount of the knowledge in the subject concerned is essential for judging the merits of such a question. Moreover, in view of the comparative infrequency of these cases the public has not yet been educated to denounce them with sufficient severity.

In recent years there has been a rapid increase in the number of scholarships and fellowships in our American universities. About twenty years ago G. Stanley Hall published, in Volume 17 of the *Forum*, an article in which he gave a list of the scholarships and fellowships which were then available for graduate work in our universities. By comparing this list with those which are now available, we shall note a remarkable change.

Those who are always looking for some kind of graft have found a fruitful field of

operation in these scholarships and fellowships. It has not been uncommon for a professor to appropriate a large part of the time of the students who were picked with a special view to their promise to develop into research men, and who needed all their time for their scholarly development. Fortunately these plunderers are becoming less common and our attitude towards scholarships and fellowships is improving. In some universities it is almost ideal.

These scholarships and fellowships have, however, some unfortunate features since they frequently attract young people to institutions and to departments which can offer very few other attractions for the graduate student. The student who is thinking of doing research work can not be warned too strongly in reference to the scholarship and fellowship traps set by various institutions which are poorly equipped for graduate work. Fortunately, many of the best equipped institutions also offer such inducements, and the most capable and most cautious students are not apt to suffer. On the contrary, such students frequently derive a great amount of good from the assistance thus received.

There is no doubt about the fact that a graduate student who comes to a university under the influence of financial assistance from the university is often inclined to consider the channels of this influence. Hence he will generally not feel quite as free, as the one who is not thus encumbered, to act independently as regards his courses or the sources where he seeks information about them. This tends to increase administrative influence at the expense of the influence of scholarship, and often leads to what deserves the name of administrative graft.

While graduate scholarships and fellowships may tend somewhat toward graft, it is not implied that they offer a very serious problem along this line. They merely call

for precaution and proper warning. The average graduate student who holds a scholarship or fellowship needs greater encouragement to become independent and to develop high scholarly ideals. The atmosphere should not create the feeling that further assistance is likely to depend on whether he takes a course with the head of the department or with some other member of the department who may have unusual administrative influence.

A large university makes many demands on the faculty for committee work and for other incidental services. It often happens that some professors fail to do their just share of such work. In the cases where this work appears useless they are to be commended for expressing in this way their disapproval. On the other hand, there is much very useful and necessary work outside of the class room, and those who are unwilling to do their full share of such work belong to a class of grafters who might appropriately be called shirking grafters.

All tendencies towards scholarly graft which have been considered thus far are generally represented in an ordinary faculty. Probably most of us have excellent illustrative examples in mind even if we fail to see where we might ourselves contribute to the list of illustrations. It may, however, be more agreeable to proceed to consider a type of graft which relates to the future American university which has at least twenty thousand students. We shall thus have the advantage of a university faculty whose members we may praise or censure with perfect freedom.

I desire to call your attention to the serious text-book graft in this future American university. Whenever a new administrative head⁴ of a large department is elected

he is practically besieged by the agents of publishers of text-books. These publishers want him to write text-books for the thousands of students in his department. They care little about the merits of the books. The fact that these books will be used in this university for several years, at least, and that they can be sold at a high price is a sufficient guarantee to publishers.

Moreover, it might happen that such a man would actually write as good books as those placed on the market by other publishers. In this case there would be a fair chance that by judicious advertising the sale of the text-books, written by our new administrative head, might become extensive, and this would mean so much more profit for the publisher.

Administrative heads of departments in our large future universities have an additional advantage in the fact that publishers will not assume the risk of publishing college text-books unless they are written or edited by such administrative heads. The smaller institutions are thus practically compelled to use the text-books written by the men in the larger universities and this reduces competition.

There are other very serious elements in this situation. Ostensibly these text-books are written on the supposition that they meet local needs better than any of those already on the market. There are fifty men in the department who have to teach the books written by the administrative head and all of these fifty men agree that these books meet local needs admirably. That is, they are perfectly agreed on this point as long as there is no change in the administrative head. If, perchance, one would hold a different view, his influence in the university to appoint heads of the departments as it would be for state legislatures to fix by law the value of π . Administrative heads can, of course, be appointed by the administrators of the university.

⁴ Heads of departments are determined by the scholars in the field represented by the department. It seems as foolish for the administrators of the

department would soon reveal his error and thereafter he could also see the situation in the true light.

In the small colleges a teacher will be inclined to call the attention of his students to points of view which appear to be an improvement over those set forth in the text. In fact, they will often call attention to other text-books in which special subjects are treated in a more satisfactory way. In the future large universities under consideration there are no temptations to indulge in any speculations which would imply that the text-book could be improved except perhaps as regards typographical errors or mistakes in the answers.

The fifty teachers using the same book are not tempted to waste their time and energy by comparing other text-books with the one in use. They are not tempted to discuss with each other in a free way such trivial questions as those involved in a study of the order in which various parts of the subject should be treated. All of these questions have been settled for them by the text-books which they are practically compelled to use and they have plenty of time for thoughts along other lines.

One of the main advantages of this situation still remains to be mentioned. The students are highly impressed by the fact that local men are wise enough to write such books as they are using. They actually have seen once or twice the authors of their text-books, and the university which has such men on its faculty secures thereby a strong claim for eminence and useful service. This fact naturally appeals to the university administration and helps to block the way towards reform.

Finally, a hopeful element appears in this situation. Some crank begins to call attention to the fact that injustice is being done. Being a crank he keeps on enumerating such things as follows: Is it reasonable

to suppose that an elementary text-book written by the administrative head of a department including fifty teachers should meet the views of these teachers as well as one selected by them from all the others on the market? Would it not be well to exclude by law text-books written by local men in those cases where a considerable number of different men are expected to teach classes by means of the same text-book?

Statements like these, and conditions enumerated above, naturally appeal to people whose sensitiveness to questions of graft has been greatly increased through decades of newspaper agitation, and our crank has an easier task than one might have supposed. He receives newspaper support, and legislative support follows. Laws are enacted which restore the freedom of discussion of text-books even in these large future universities. In view of the fact that these laws are enforced, this text-book graft becomes a thing of the past. As a result, the really meritorious college text-book lives longer and is consequently sold to the student at a more reasonable price.

Whether this glimpse into the future university is justified by the present trend can not be considered here. Our aim was to call attention to the dangers whose seriousness naturally appeals to us in different degrees. It is scarcely necessary to add that these dangers are national in scope. Whatever view we may have of them it seems clear that we should consider their bearings as behooves those engaged in research.

Text-book writing is sometimes attended at present by a feature which appeared to be too unjust to attribute to our future large university. It has often happened in large undergraduate classes that mimeographed notes which could scarcely be deciphered by the students were substituted

for an excellent text-book while a mediocre text-book was being written. Such procedures call for the strongest condemnation, especially since those who are being abused in this way are not in position to defend themselves properly.

Having exhibited a few tendencies towards scholarly graft the question arises whether a study of such matters is likely to promote scientific research. As a matter of fact an affirmative answer to this question is necessary to justify the preceding remarks on an occasion of this kind. Scientific research is based on a profound conviction that truth is desirable, and such research seems to thrive best in an atmosphere where all truths are welcome and where all honest efforts to arrive at the truth are respected.

This society is based, in part, upon the theory that there are wide differences as regards scholarly achievements among the faculty as well as among the students. It calls for observations as regards scientific achievements and for a public expression of conclusions relating to such achievements. These things are intimately connected with the questions considered above and hence these questions seemed appropriate even if they affect only indirectly our main interests.

In financial circles there seems to be a tendency to welcome the most searching scrutiny on the part of the public. Our scholarly methods should be freely open to the same kind of scrutiny. Practices which suffer thereby would be apt to become worse and to suffer more severely through a later investigation. It seems also very desirable that we should institute such investigations from within before they are suggested by a dissatisfied public.

There is a general impression that scholars are too poorly paid and that we should not interfere with the efforts which some of

them are making to increase their incomes. On the other hand, the fact that a rule of the University of Paris provides that no professor shall be able to increase his salary beyond twenty thousand francs by accepting numerous teaching positions, shows that in a leading intellectual center it has appeared desirable to limit the professor whose financial ambitions interfere with what appear to be the highest university interests.

In view of the fact that there is such a large army of men engaged in scientific investigation it is reasonable to expect to find in our own ranks a great variety of types of mind. Many of us doubtless believe that some subjects which have found a place in respectable society as regards subjects of learning are practically graft-subjects. Subjects where the brilliant advances of one generation dwindle repeatedly into nothing through the scrutiny of the following generation, must convey a strong odor of graft to a scientific mind. This is true in spite of the fact that these subjects frequently relate to things about which we would all sincerely wish to have more light.

One object of a university course should be to lead the mind of the young towards useful channels of thought and to warn them against those subjects whose main capital is wasting the time of the student by discussing things about which we know nothing; or, what is still worse, by cultivating the dishonest state of mind which delights in pretensions of knowledge where there is no knowledge. The greatest foe of knowledge is the pretended knowledge which can not now be disproved, and the greatest danger which besets the students who are seekers of truth is the net of glittering but baseless generalities which are sometimes spun out before their eyes under the name of undergraduate university instruction.

Fortunately our own society is dealing with subjects where progress is permanent and where sham progress finds little room. It is true that these subjects reach into those of a different type and that Barnums and Ringling Brothers sometimes arise in our midst, but they do not represent the normal phase of our subject. We are living in houses built of strong material and hence we should not be afraid to throw stones at all appearances of graft. Our progress in the past has been largely due to an honest admission of unknown elements in our subjects. We have represented these by symbols and thus developed an algebra, which has led to marvelous advances.

This algebra of science naturally does not appeal to those whose mental caliber is such that they can enjoy only fiction, but it is this algebra which has made possible many of the conveniences of our fiction readers. It is an interesting sight when men use the telephone and the electric railway to call and to attend meetings for the purpose of belittling the value of science. These things are, however, becoming more rare, and one of the important duties of the scientific investigators is to maintain high ideals within their own ranks. These permeate the atmosphere which surrounds their work, and a favorable atmosphere is one of the essentials for vigorous scientific development.

Another important reason for maintaining the highest ideals among investigators is based upon the fact that the career of the investigator offers many excellent openings for the crook, and this constitutes one of the most alarming features as regards the permanent dignity of our profession. In fact, few other lines of work can offer more opportunities to those inclined to indulge in unfair practises. We all agree that some of the most important investiga-

tions require long periods of years, and that the investigator who has proven his ability should not be required to give an accurate account of how he is spending his time.

What a splendid opportunity these conditions afford to the crook. He too likes to be free from giving an accurate account of himself, and if he can deceive his superiors for a period of years by creating the impression that he will soon do something that is very important, he may have arrived at a position of independence before the truth becomes known. That such things are happening around us, few would probably be inclined to deny. When the lot of the investigator was a much harder one there were few temptations for the crook in this field, but with the improvement of conditions these temptations increase, and those who desire to be honest can not welcome too heartily the most searching investigation as regards our outward research practises.

There seems to be a growing respect for scientific investigations, and it is our duty to maintain this respect. With the increase of funds devoted to investigation, there naturally goes a growing interest in investigators and consequently a growing scrutiny of their practises. As these funds come more largely from the masses we are becoming more subject to waves of popular opinion. History furnishes many instances of how these waves may become agitated by disclosures of irregular practises. Hence a deep loyalty to the highest interests of scientific investigation carries with it a deep interest in the improving ideals of the investigators.

Unless these ideals are kept relatively high and a large number of useful discoveries continue to result from investigations, there seems no good reason to assume that scientific investigation can permanently maintain its position. The vicissitudes of

scholars in past ages serve to remind us of sad possibilities, and they should serve to spur us to the noblest efforts. The greatest danger which besets investigation is corruption within the ranks of the investigators. It still remains to be proven that the lot of the investigators in pure science can be made permanently attractive without supplementing them by crooks.

We all rejoice in every new evidence of the benefits derived from scientific discoveries. Those which reach every corner of our land are especially fraught with significance in view of their widespread effect in inspiring general confidence in the value of scientific investigation. Hence we have good reason to rejoice at this time on account of the important rôle scientific sanitation played in the digging of the Panama Canal. Such evidences have been so numerous in recent years as to create a new danger: viz., the unthinking mass may become too easy a prey to the extortioner who may use these facts to secure an undue amount of money from them. Oppression even in the name of promotion of science can not be countenanced by those interested in the permanent service of our subject.

In closing, I desire to call your attention to the fact that one of your serious duties is to make people forget that you were elected as members of the Sigma Xi, just as people ought to forget that you are a graduate of a college or that you have the doctor's degree. If, when you think of a man who is over forty years old, the thing that is prominent in your mind is that he graduated from Harvard or that he took his doctor's degree at Paris, it is almost certain that the man does not amount to much. If our future attainments do not overshadow our local university distinctions we have not been a success.

Your entrance into this society should overshadow the honors achieved through

your good work in the high school; but compared with your future achievements, these present honors should sink into insignificance. A few years ago we thought of President Wilson as the president of Princeton, but to-day we think of him as president of the United States. Those of us who think of both of these types of positions as political achievements will naturally think of the latter achievement first. As far as the former position implies scholarly achievements, it can, of course, not be compared with the latter.

In purely scholarly achievements the comparison is simpler, and, in this case, we should always view with suspicion the man of forty who is still regarded as a Harvard or a Yale product; or who is still distinguished by the fact that he has a Ph.D. from a noted institution. I can not help thinking of such a man scientifically as still a babe in long dresses. Desirable as these distinctions may be in early years, they are only of temporary prominence as regards the man who actually is worthy of them. To avoid misunderstanding, I desire to emphasize the fact that I believe very heartily in such scientific distinctions as those which are attached to your election to this body. I sometimes think we have too few opportunities to mark in a public way, the various steps towards higher and higher scientific attainments. The fact which I desired to make perfectly clear is that our eyes should always be fixed on still higher attainments. There are too many intellectually satisfied people among us—too many whose scientific achievements could no longer be verified if they had not been securely established on parchment with India ink.

We welcome you into a society which stands for infinite progress in fields of infinite riches, a society which recognizes that our fathers knew less than we do and that

our children will know more than we know, a society which aims to establish fraternal relations among its members and which recognizes that hearty and continued co-operation is essential if we would succeed in securing those rich rewards of mind and body which past scientific discoveries lead us to expect to find in the unexplored regions. G. A. MILLER

THE FOUNDATION OF THE GEOLOGICAL SOCIETY OF AMERICA¹

THERE was an "American Geological Society" in 1832 at New Haven, Conn., but it faded out in the glare of the chemical and physical sciences which bloomed brilliantly at that time in New Haven. I have not been able to get any detailed information concerning it.

About the same time was organized the Geological Society of Pennsylvania, 1832. At a meeting of February 22, 1832, the officers were John R. Gibson, president, Nicholas Biddle, vice-president; Stephen S. Long, vice-president; Henry S. Tamer, treasurer; Peter A. Browne, corresponding secretary; George Fox, recording secretary.

This society sent out a circular signed by John Gibson and George Fox announcing the organization and asking assistance in getting information and specimens. The organ of publication was Featherstonhough's *Monthly American Journal of Geology*.

This society seems to have aimed to develop the geology of Pennsylvania specially, but its plan of operation covered other states. It came quickly into competition with the Philadelphia Academy of Science. Its transactions were published in Featherstonhough's *Journal*, at first, but as that *Journal* passed through only one volume, it is unknown to me whether the society survived long after the death of the *Journal*. It appears that there was close sympathy between them, and it may be presumed that Mr. Featherstonhough was the instigator and prime mover of both.

¹ Response by Professor N. H. Winchell at the banquet of the Geological Society of America, Princeton, N. J., January 1, 1914.

There may have been other local geological societies in the country since 1832 whose records have not been published, but I have not heard of any.

The period of discussion and gestation prior to the birth of the present Geological Society of America extended from August, 1881, to August, 1888, *seven years*.

A few weeks before the 1881 meeting of the American Association for the Advancement of Science, at Cincinnati, Professor Chamberlin called on the speaker at his home in Minneapolis. The Western Society of Naturalists had been organized several years earlier, and one of its annual meetings was announced to take place at some point in the Mississippi Valley. In the conversation which took place in my parlor the suggestion was made by the speaker that the geologists of the western part of the country ought to be organized into a Mississippi Valley Geological Society. Professor Chamberlin immediately fell in with the idea, and it was agreed by us that the project should be broached at the approaching meeting of the American Association for the Advancement of Science at Cincinnati. But this idea expanded, in conversation with geologists at that meeting, into greater dimensions, and it was resolved to organize the geologists of America in a general society.

The first informal meeting embraced those present at Cincinnati and was held in the room of Section B, at 5 P.M., August 18, 1881. A committee was chosen to draft a constitution, consisting of George C. Swallow, of Missouri; N. H. Winchell, of Minnesota; S. A. Miller, of Ohio; Wm. J. Davis, of Kentucky; John Collett, of Indiana, and H. S. Williams, of New York.

On meeting the committee elected Winchell chairman and Williams secretary, and Miller was designated to draft a constitution for the proposed society. This constitution was presented the next day at an adjourned meeting of the committee, but after considerable discussion it was finally decided that it was best to defer more definite action to the next meeting of the American Association, and that meantime the committee prepare and distribute

widely a circular asking for the opinions of geologists generally, the replies to be reported at the next meeting of the Association, which was to be held at Montreal. Before the issuing of this circular John R. Proctor, state geologist of Kentucky, was added to the committee. This circular was drawn up by the chairman of the committee and, on submission to the members of the committee, was approved unanimously by them. It was based almost entirely on a previous rough draft prepared by Williams and presented to the committee by him at one of the preliminary meetings at Cincinnati. Its main points are as follows:

The committees are desirous of eliciting opinions from all active and professional geologists, to the end that more judicious and effective action may be taken at the next meeting.

1. The science of geology, with its kindred branches of paleontology and lithology, has made rapid progress in America—perhaps more rapid than in any other country—in the last twenty years.

2. The literature of geology is largely distributed through numerous scientific journals, and in the proceedings of miscellaneous scientific societies, to procure which is difficult and expensive.

3. The present facilities afforded through the American Association for the Advancement of Science are insufficient, and unavailable by the working geologists of the country—because (a) The meetings are held in the summer, which is the geologist's working season. In order to be present he must interrupt his work and leave the field, often at considerable expense, especially if he has a party with him. (b) Its brief meetings partake largely of the nature of vacation pleasure-parties, and much of the time is engrossed by reception, gratulation and excursions. (c) There is no sufficient avenue of publication of the work of geologists. (d) The association has become so large, widespread and popular in its work, membership and organization that its spirit necessarily, and properly, is not favorable to the development of any special work through its own agency.

4. The geologists, as a body, have no way of expressing their views on important state, national or international measures, except through the medium of the American Association, at the meetings of which there is a perceptible and increasing lack of attendance and interest on the part of geologists, in consequence of which the actual views of the geologists of the country on such questions can not be obtained and expressed correctly.

5. There is no strictly geological magazine or journal in America.

6. There is no strictly geological society in America.

7. There are numerous such societies and journals in Europe as well as journals and societies devoted exclusively to the branches of paleontology and mineralogy.

The committee desire also to disclaim any intention to trespass on the field and plans of the American Association for the Advancement of Science, or to criticize it in any way as to the discharge of its functions. Its tendency is to popularize science and to advance its acceptance by the world by diffusing scientific knowledge, and by announcing important discoveries, and as such, its sphere of activity is one that no special scientific body can occupy, but which still will be aided by the existence of tributary organizations, such as that contemplated by this circular.

At Montreal responses were read from the following geologists: S. A. Miller, James Macfarlane, Franklin Platt, W. P. Blake, J. D. Dana, P. A. Chadbourne, J. E. Todd, E. W. Claypole, Wm. M. Davis, M. C. Read, Chas. E. Billin, W. H. Pettee, Geo. H. Stone, John Collett, R. E. Call, Warren Upham, W. G. Platt, C. A. Ashburner, J. T. Cross, G. K. Warren, A. Winchell, Robert Bell, P. W. Schaeffer, S. E. Tillman, E. O. Ulrich, C. H. Hitchcock, Edward Orton, W. J. Davis, J. W. Dawson.

The official report of the proceedings at Montreal states that A. Winchell was chosen chairman and C. H. Hitchcock secretary. Several sessions were held. Ninety answers to the circular which had been issued were reported by the chairman of the committee,

all but two of which spoke favorably of the project. The secretary (Williams) reported answers from thirty persons, and S. A. Miller reported answers from six persons, all favorable, making a total of one hundred and twenty-six opinions in favor of and only two dissenting from the formation of the proposed society.

A committee consisting of Jed Hotchkiss, R. Whitfield and C. H. Hitchcock, appointed to consider the situation, recommended that the first step to be taken should be the establishment of a geological magazine. This report was accepted and adopted; the Cincinnati committee also reported a proposed constitution, which was discussed and laid upon the table pending further labors by the committee and a report at the Minneapolis meeting in 1888.

At the Minneapolis meeting of the American Association for the Advancement of Science (1883) those who had been active for the proposed geological society met August 21, and listened to further discussions and some objections. Some dilatory motions were brought forward, viz., that a committee be appointed to confer with the Mineralogical and Geological Section of the Philadelphia Academy of Sciences with reference to the formation of an American Society and the establishment of a geological magazine. Prior to this a committee had been appointed with instructions to confer with Major J. W. Powell to ascertain what encouragement could be afforded by him in the support of a geological magazine. These special committees, however, accomplished nothing, except to delay the project, and to discourage those who were in favor of the proposed society; and the friends of the new movement became very much discouraged by the expression of unfavorable views at Minneapolis. These adverse opinions were stated by several of the oldest and most prominent geologists; and they served to dampen the ambition of those who, though younger, had been zealously promoting the proposition.

Four years later various causes led some of these opponents to change their minds and to solicit a continuation of the plan that had

been proposed. And in particular the speaker recalls such correspondence with Dr. J. S. Newberry.

The chairman and the secretary of the moribund organization, Winchell and Hitchcock, convinced that nothing would be done by other parties, under implied instructions and responsibility from the meeting at Minneapolis, by virtue of their office sent out a call to meet at Cleveland, Ohio, in connection with the American Association for the Advancement of Science, 1888. The call as issued provided that the new society should be composed only of members of Section E of the American Association. This was in consequence of fear, expressed by some of the older geologists, that such an organization would clash seriously with the Association; and their love for the Association, with which they had been connected actively for many years, was greater than for any new geological organization, which appeared to them like a phantom which would be likely to have only an ephemeral existence.

Meanwhile several geologists, depending largely on the action of the Montreal meeting, and on the frequently stated advice of individual geologists, unwilling to delay longer the issuance of a geological magazine, boldly took the initiative and established the *American Geologist*, the first number appearing January, 1888. The call for the Cleveland meeting appeared in the *Geologist* for June, 1888.

It is enough to say, further, that this call met a cordial reception and that at Cleveland very much renewed interest was evident. Committees were appointed to prepare a constitution, and this constitution was adopted at a meeting held at Ithaca, New York, in December, 1888, the present meeting being the twenty-fifth anniversary of its adoption.

ALEXANDER FRANCIS CHAMBERLAIN

DR. ALEXANDER FRANCIS CHAMBERLAIN, professor of anthropology in Clark University, died April 8, 1914. He was born in Kenninghall, England, in January, 1865. In early life he came to Canada and took the degree of A.B. at the University of Toronto in 1886, and A.M.

in 1889. From 1889-90 he was librarian of the Canadian Institute at Toronto. In 1890 he was appointed to a fellowship in Clark University, where he took the Ph.D. degree in 1892. Shortly after he was appointed lecturer in anthropology and later promoted to a full professorship.

Professor Chamberlain was an expert bibliographer and editor. For many years he contributed systematic bibliographical notes to the *American Anthropologist*, which have been of great value to American students, especially since his great linguistic knowledge enabled him to give digests of all important foreign publications. It is in this respect that his loss will be most keenly felt. As an editor he was for many years in charge of the *Journal of American Folk-Lore* and actively associated with President G. Stanley Hall in the editorship of the *Journal of Religious Psychology*. He was also an associate editor of the *American Anthropologist* and of the *American Antiquarian*. He was an important contributor to the *Encyclopedia Britannica* and many other reference books. As a writer, he possessed more than average skill, having contributed many charming articles to the *Atlantic Monthly* and other magazines.

His special line of research was linguistics. In 1891 he made a special study of the Kootenay Indian language of British Columbia under the auspices of the British Association and collected considerable data on their culture; unfortunately, the greater part of this is still unpublished. In addition to the study of certain Algonkin linguistic problems, Professor Chamberlain worked over the linguistics of South America and prepared a map of the continent similar to the famous Powell map of North America. This work was recently published and, though still to occupy the attention of the author, had he lived, is probably about as complete as the data available make possible. Though necessarily tentative, it marks a distinct advance in South American anthropology.

His best known works are the "Child and Childhood in Folkthought" (1896) and "The Child: A Study in the Evolution of Man" (1900), subjects which were quite suggestively

developed in his lectures to students of psychology and education. C. W.

THE GENERAL EDUCATION BOARD

THE spring meeting of the General Education Board—the foundation endowed by Mr. John D. Rockefeller—was held on May 29. In attendance were Chas. W. Eliot, Albert Shaw, H. B. Frissell, Anson Phelps Stokes, John D. Rockefeller, Jr., F. T. Gates, E. L. Marston, Jerome D. Greene, Starr J. Murphy, Wallace Buttrick and Abraham Flexner. Ambassador Page, President Judson and Dr. Wickliffe Rose were absent abroad. The membership of the board was increased by the election of President George E. Vincent, of the University of Minnesota.

At the close of the meeting announcement was made that appropriations aggregating \$1,400,000 had been made. The most important of these was a gift of \$500,000 to the medical school of Yale University. As had been previously announced, the General Education Board has decided to provide funds necessary to enable properly located and organized medical schools to command the entire time and energy of their teachers in the main departments of medicine and surgery. For this purpose a million and a half dollars has already been appropriated for the Johns Hopkins School, and \$750,000 for Washington University. This gift of \$500,000 to the Yale Medical School was made on condition that the school procure complete teaching and medical control of the New Haven Hospital, and that the teachers in the main clinical branches be placed on the full-time or university basis.

In conformity with its previous policy of making gifts to increase the endowment and extending the usefulness of promising and serviceable institutions in various parts of the country, the following appropriations were made:

Stevens Institute of Technology	\$250,000.
Elmira College	100,000.
Hendrix College	100,000.
Washington and Lee University	125,000.
Wells College	100,000.
Wofford College	33,000.

Increased appropriations were made to develop the work in secondary education which the board has been carrying on in the south for ten years. The board has maintained professors of secondary education in southern universities and inspectors of secondary schools who have devoted their time to the creation and development of high schools in their several spheres.

The sum of \$36,500 was appropriated for the maintenance of rural school supervisors in each of the southern states. These supervisors are concerned with the improvement of country schools and with the introduction into them of industrial training and domestic science. The annual subscription of \$10,000 toward the current expenses of Hampton Institute was increased to \$25,000, an annual subscription of \$10,000 was made to Tuskegee Institute, and one of \$15,000 to Spelman Seminary, Atlanta.

Farm demonstration work on an educational basis was originated by the General Education Board. The plan was conceived by the late Dr. Seaman A. Knapp. So far as the southern states are concerned, congress now assumes the work heretofore supported by the General Education Board, objection having been made to the payment of the officers of the Department of Agriculture by a private contribution. The board will, however, continue its co-operation with agricultural colleges in the work. For this purpose, \$20,000 was appropriated for farm demonstration in six counties in Maine and for boys' and girls' clubs in that state. A further appropriation of \$10,000 was made for similar work in New Hampshire.

To improve education in the rural districts the board has resolved to offer to support in connection with state departments of education, rural school agents. An appropriation of \$50,000 was made for the work in fifteen states. A general agent will be appointed to keep the several state movements in touch with one another. The board resolved to authorize a study of training for public health service and of the organization of public health service in England, Germany, Denmark and other

foreign countries. When the facts have been ascertained a conference will be held and a concrete scheme formulated for schools of public health.

THE PACIFIC ASSOCIATION OF SCIENTIFIC SOCIETIES

The fourth annual meeting of the Pacific Association of Scientific Societies was held at the University of Washington, Seattle, May 21-23, 1914. There were about 150 men from the Pacific coast and from Hawaii attending the various societies meeting at that time. Of the sixteen constituent societies the following held meetings: The Cordilleran Section of the Geological Society of America, The Seismological Society of America, Pacific Coast Branch of the American Historical Association, The Pacific Slope Association of Economic Entomologists, Pacific Coast Paleontological Society, The Cooper Ornithological Club, Biological Society of the Pacific Coast, California Section of the American Chemical Society, Puget Sound Section of the American Chemical Society, and the San Francisco Section of the American Mathematical Society. The following societies did not hold meetings at this time: The Technical Society of the Pacific Coast, California Academy of Sciences, Astronomical Society of the Pacific, The Geographical Society of the Pacific and the San Francisco Society of the Archeological Institute of America. In addition to the above eleven societies of the Pacific Association the following six societies of the Pacific Northwest joined with the Association: Seattle Society of the Archeological Institute of America, Oregon Section of the American Chemical Society, The Northwest Association of Teachers of History, Government and Economics, Inter-Mountain Section of the American Chemical Society, The Le Conte Club, the proposed Pacific Coast Branch of the American Political Science Association and the Washington Society of Social Hygiene.

The general session of the Association was held on Saturday evening, before which spoke Acting President Landes, of the University of

Washington. President J. C. Branner, Stanford University, gave an address on "Science and the State." Dean J. Allen Smith, University of Washington, read a paper on "The Citizen and the State." The third paper was given by Professor J. C. Merriam, University of California, on "The Geological History of the Human Family and Its Bearing on the Race Problem." In 1915 the Pacific Association will hold no meetings; the constituent societies will join with their eastern societies at the Fair at San Francisco. At this meeting of the association a constitution was approved by the executive committee whereby the Pacific Association will become the Pacific Division of the American Association for the Advancement of Science. The constitution was referred to the constituent societies for their action. Since there is to be no meeting in 1915 the change of associations is to take place at the end of the 1915 meeting of the American Association at San Francisco in August of that year, provided that by that time two thirds of the constituent societies have approved and signed the constitution and also provided that the Pacific Division is ready with its officers to take up the work of the Pacific Association.

SCIENTIFIC NOTES AND NEWS

DR. JACQUES LOEB, of the Rockefeller Institute for Medical Research, has been elected a corresponding member of the Paris Academy of Sciences in the section of anatomy and zoology, in succession to the late Lord Avebury.

PROFESSOR JOHN HOWARD APPLETON, for over fifty years an instructor at Brown University and since 1868 head of the department of chemistry, will retire at the end of the present academic year with the title of professor emeritus.

At the celebration of the seventy-fifth anniversary of the founding of the University of Missouri, held at Columbia, Mo., June 3, Professor Cassius J. Keyser delivered an address on behalf of the alumni. At the commencement exercises the university conferred upon him the degree of doctor of laws.

DR. MARK J. SCHEONBERG has received the Lucien Howe prize of the Medical Society of the state of New York for his research work on ocular anaphylaxis.

MR. CLIFFORD RICHARDSON, consulting engineer, has been elected president of the Association of Harvard Chemists, and vice-president of the Harvard Engineering Society of New York, for the ensuing year.

DR. THEODORE C. MERRILL, recently assistant pathologist in the office of forest pathology of the Bureau of Plant Industry, has been appointed medical assistant in the Bureau of Chemistry.

THE C. M. WARREN committee of the American Academy of Arts and Sciences has made the following grants:

To Professor George H. Burrows, of the University of Vermont, a grant of \$250 for work connected with the measurement of equilibrium concentrations in certain reactions of organic chemistry, with the special purpose of determining the free energies of formation of the compounds involved.

To Professor R. F. Brunel, of Bryn Mawr College, an additional grant of \$400 for the purchase of a polarimeter to be used in connection with his work on equilibria in organic reactions in which optically active radicals are concerned.

To Professor S. Lawrence Bigelow, of the University of Michigan, a grant of \$200 for the promotion of his study of osmotic membranes, especially those of a metallic nature.

MAYOR MITCHEL, of New York City, accompanied by President Thomas Churchill of the Board of Education and City Chamberlain Henry Bruere, have this week visited cities of the central west to inspect their public schools and teaching systems.

THE Harrington lectures of the medical department of the University of Buffalo, by Professor Ludwig Pick, of Berlin, were announced for the evening of June 2 and in the afternoons of June 3 and 4. The title was "Some Recent Advances in Pathological Anatomy."

DR. IRA REMSEN, of the Johns Hopkins University, addressed a large University of Illinois audience on May 18. His subject was "My Acquaintance with Liebig and Wohler."

He addressed the members of the Chicago Chapter of the Sigma Xi at their Spring Quarter dinner on May 19 upon "Reminiscences of Rowland and Sylvester."

At the graduate school of agriculture, to be held at the University of Missouri, Columbia, Mo., June 29-July 24, a course of forty lectures on genetics will be given by Professor A. D. Darbishire, of the University of Edinburgh; Professor E. M. East, of Harvard University; Professor M. F. Guyer, of the University of Wisconsin, and Dr. J. A. Harris, of the Carnegie Institution. Dr. Otto Appel, of the Imperial Biological Institute at Dahlem, Berlin, will lecture at this school on the diseases of potatoes and cereals.

At the 329th meeting of the New York Electrical Society, held at Columbia University, on May 25, Dr. L. A. Bauer gave an illustrated lecture on "The Non-magnetic Yacht *Carnegie*, Her Work and Her Cruises." This was followed by a brief informal talk on "Aerial Navigation," by Lieut. John Cyril Porte, R. N., with especial reference to the proposed Rodman Wanamaker transatlantic flight.

THE University of Pennsylvania library has received through Dr. John K. Mitchell and Mr. Langdon Mitchell about 500 volumes, forming a portion of the library of their father, the late Dr. S. Weir Mitchell.

THE class of 1910, general science course, has presented to the Cooper Union, New York City, a memorial tablet for the late Professor William A. Anthony. Mr. John F. Hanbury, a graduate of the class, said that Professor Anthony had established at Cornell University the first electrical course either in Europe or America. Professor Edward L. Nichols, of Cornell, and President John W. Lieb, of the New York Edison Company, gave tributes to the genius of Professor Anthony.

THE University of Birmingham council has passed the following resolution: "That the council desires to record its deep sorrow at the death of Professor Poynting, who so faithfully served the Mason College and the university for thirty-four years. During his distinguished career as professor of physics he

was not only an inspiring teacher and investigator, but bore a considerable part in the development of the college and of the university. His keen interest in all that concerned the university, its staff, and its students, his genial and attractive personality, will be long and affectionately remembered; his death leaves a gap which it will be most difficult to fill."

DR. ALFRED E. BARLOW, of Montreal, distinguished for his work in Archaean and mining geology, a former member of the Geological Survey of Canada and former president of the Canadian Mining Institute, was drowned in the wreck of the "Empress of Ireland" on May 29. Dr. and Mrs. Barlow were together on a vacation trip to England and both were lost in this terrible catastrophe.

WE regret also to announce the untimely death, at the age of thirty-eight years, of Jesse J. Myers, assistant professor of physiology and zoology at the Michigan Agricultural College, East Lansing, Michigan. Professor Myers was born in Illinois and graduated at the University of Illinois with the degree of B.S. in 1901. Since then he has been on the staff of the Michigan institution, having spent some of his vacation months in study at the Universities of Illinois and Wisconsin. Early in April he went to New Haven to enter the Sheffield laboratory of physiological chemistry of Yale University; and he died after a very brief illness from typhoid fever in that city on May 28.

DR. PAUL VON MAUSER, inventor of the Mauser rifle, has died at Berlin, aged seventy-six years.

THE U. S. Senate has passed the Agricultural Appropriation bill, with a provision prohibiting the acceptance by government employees of funds from the General Education Board or similar institutions.

THE Army appropriation bill that passed the U. S. Senate some weeks ago provides that the appropriation for the library of the Surgeon-General's Office shall be conditional on the merging of this library with the Congressional Library. Neither the surgeon-general

nior the librarian of congress was consulted, and the plan is opposed by them and by all well-informed physicians and men of science. It may be assumed that the amendment will not be concurred in by the House, after the question has been brought properly to its attention.

THE Association of German Men of Science and Physicians will hold its eighty-sixth annual meeting this year at Hanover from September 20 to 26.

THE international committee for the International Congress of Anatomy has decided that the next meeting shall be held at Amsterdam during August, 1915.

THE Eugenics Research Association will hold its next annual meeting on Friday, June 19, and Saturday, June 20, 1914, at Schermerhorn Hall, Columbia University, New York City. The program will consist of papers by members, a symposium upon the subject: "The most pressing topics for research in eugenics," open discussions, and a general experience meeting for institutional officers and eugenics fieldworkers. In order that the details of the program of papers may be completed as early as possible, contributors are requested to notify the secretary *not later than May 21*, giving the title of the paper and the amount of time required.

SIR ARTHUR EVANS has presented to the museum of the University of Cambridge the last instalment of a set of objects selected from the collections of his father, the late Sir John Evans. The gift consists of 121 specimens ranging in date from prehistoric times to the eighteenth century. All the specimens were found in Cambridgeshire and the adjacent counties.

MRS. RUSSELL SAGE has given to the State Museum, Albany, a series of 106 bird paintings by Louis Agassiz Fuertes, of Ithaca. The exact amount contributed was not made public. These paintings were made by Mr. Fuertes within the last two or three years for reproduction in a comprehensive book on the birds of New York State.

BULLETIN 553 from the Harvard College Observatory signed by the director, Dr. Edward C. Pickering, and dated May 26, states that a cablegram received at this observatory on May 21, from Professor C. D. Perrine, director of the Observatorio Nacional, Cordoba, Argentina, states that the orbit of Zlotinsky's Comet is found to be similar to that of Herschel's Comet of 1790. Professor Edwin B. Frost, director of the Yerkes Observatory, writes that the comet was seen by several observers on May 20 and 22 with the naked eye. Estimates of its magnitude on May 22, with a clear sky, determined it to be equivalent to a fifth magnitude star. Photographs were obtained by Professor Barnard on May 18, 20 and 22, the last of which showed a tail at least 12° long, extending to the edge of the plate, resembling the tail of Gale's Comet as photographed by Professor Barnard in 1912. Photographs by Mr. Parkhurst with a 15° U. V. objective prism, May 20 and 22, show the usual commentary spectrum with large knots representing the CN band ($\lambda 3883$), and the blue band ($\lambda 4737$), known as the "fourth carbon," beside numerous fainter ones. On May 20 the green band ($\lambda 5165$), known as the "third carbon," was well shown.

UNIVERSITY AND EDUCATIONAL NEWS

A GIFT of \$100,000 for the erection of the first of Cornell University's residential dormitories is announced. The name of the donor is withheld.

NATHANIEL H. STONE, of the class of 1875, has made an unrestricted gift to Harvard University of \$50,000 in memory of Henry Baldwin Stone of the class of 1873.

THE University of Pennsylvania is given \$25,000 under the will of Miss Elizabeth S. Shippen.

MR. ROBERT C. OGDEN bequeathed \$20,000 and a contingent interest in one third of a \$50,000 fund to the Hampton Normal and Agricultural Institute.

THE supreme court of Massachusetts has decided that the Massachusetts Institute of

Technology may sell its Boylston street land, but only subject to the restrictions and encumbrances of abutters established by the grant of the land to the institute in 1861 by the legislature. The institute will therefore probably retain its present site for part of its work.

APPOINTMENTS, including changes in title, have been made at Harvard University as follows:

Comfort Avery Adams, Abbott and James Lawrence professor of engineering.

Masaharu Anesaki, professor of Japanese literature and life.

Edwin H. Hall, Rumford professor of physics.

Elmer Peter Kohler, Abbott and James Lawrence professor of chemistry.

Roger Irving Lee, professor of hygiene.

Manoel de Oliveira Lima, professor of Latin-American history and economics.

Robert Williamson Lovett, professor of orthopedics.

William Fogg Osgood, Perkins professor of mathematics.

Wallace Clement Sabine, Hollis professor of mathematics and natural philosophy.

Frank Lowell Kennedy, associate professor of engineering drawing.

Howard Thomas Karsner, assistant professor of pathology.

At Clark College Dr. Robert H. Goddard, late research fellow in Princeton University, has been appointed instructor in physics. Professor Carey E. Melville, assistant professor of mathematics, has taken on the duties of registrar of the college.

DR. SAMUEL RITTENHOUSE, professor of biology at Olivet College, has been elected associate professor of zoology in the University of Southern California.

DR. JOHN W. COX, graduate of the Syracuse University College of Medicine in 1912 and afterward instructor in pathology at Syracuse, has been appointed assistant professor of pathology in the State University of North Dakota.

DR. A. F. SHULL, assistant professor of zoology in the University of Michigan, has been promoted to a junior professorship.

RYLAND M. BLACK, A.M., professor of history and political science in the State Science School, Wahpeton, North Dakota, has been elected to the presidency of the State Normal Industrial Institute at Ellendale of that state.

MR. G. P. THOMSON, scholar of Trinity College, Cambridge, and son of Professor Sir J. J. Thomson, has been appointed to a mathematical lectureship at Corpus Christi College.

DISCUSSION AND CORRESPONDENCE

HAS THE WHITE MAN MORE CHROMOSOMES THAN THE NEGRO?

In a recent number of SCIENCE (May 15, 1914), Professor Michael F. Guyer complains that in my recent book on "Heredity and Sex" I have given an erroneous impression concerning the relation of his work on human spermatogenesis to that of Montgomery on the same subject. Professor Guyer objects to my statement that while Montgomery's account confirms his own as to the number of the chromosomes it "is in disagreement in regard to the accessory." I think my statement is correct, but in order that the reader may judge for himself, let me quote Montgomery's own summing up:

But Guyer concluded that the two allosomes [sex chromosomes] always pass undivided to one spindle pole in the primary spermatocytes, reaching then only half of the secondary spermatocytes, and in these dividing presumably equationally. He consequently argued two classes of spermatozoa are produced in equal numbers. . . . That is to say, he overlooked the variability in behavior of the allosomes specially studied by me.

After giving his reasons for thinking that this *variability* in the behavior of the allosomes is a normal process, Montgomery concluded that there would "be four classes of spermatozoa and not simply the two classes distinguished by Guyer" (p. 10). And in another connection Montgomery writes . . . if there be only two classes of sperm, as Guyer argues, and one kind of egg, this should result in equal numbers of the sexes and not in the ratio actually known.

These comparisons that Montgomery has himself made seem to more than justify my

remarks that he is not in agreement with Guyer in regard to the accessory. Guyer refers to this matter as only a "slight discrepancy" but to my own way of thinking, it is the only evidence (in default of better evidence, unfortunately) on which we can at present judge concerning the nature of these bodies that Guyer identifies as the sex chromosomes. Irrespective, therefore, of whether Guyer is right or wrong, it still seems to me that Montgomery's statements can not properly be said to be like those of Guyer except for a "slight discrepancy."

It may be invidious to point out here that the kind of evidence that Guyer admits in favor of the two chromosomes in man being sex chromosomes is of the same sort as the evidence that he has brought forward for similar bodies in birds. The recent thoroughgoing analysis of Pearl and Boring has made apparent that this kind of evidence is in itself inconclusive and unconvincing. The experimental evidence indicates very strongly that in birds the female is heterozygous for a sex factor.

There is another and not unimportant difference between Guyer and Montgomery. Guyer states that a second pairing of the ordinary chromosomes takes place in man. Montgomery says:

I have seen no evidence of any kind of such a pairing of chromosomes in the secondary spermatocytes, neither in my own material nor in that received from Guyer, though I have examined fully two hundred division stages of these cases.

While the second point does not bear directly on the "disagreement" in regard to the sex chromosomes, it raises a doubt as to the value of material that can lead to such diametrically opposed results, for the conflicting statements relate to the same identical preparations.

In order that no misunderstanding may arise I may add that I am entirely in sympathy with the view that in the human race the male is heterozygous in a sex factor; for the experimental evidence relating to sex-linked inheritance strongly indicates that this is the case.

It is with great interest I note in the last paragraph of Guyer's paper a hint (or is it

intended as an announcement?) that the white man has more chromosomes than the negro—a point of view I mentioned¹ in the book under discussion as a possible way of harmonizing Guyer's results with those of v. Winiwarter. If the suggestion is established, some revision may be necessary concerning the Mendelian expectation for the inheritance of skin color in the black-white cross.

T. H. MORGAN

SCIENTIFIC BOOKS

INTRODUCTION TO THE NEW STATISTICS WITH SPECIAL REFERENCE TO THE NEEDS OF BIOLOGISTS

THE number of guides to modern statistical methods consequent upon the realization that mathematical analysis is necessary for the full interpretation of series of observations is now so large that it may be helpful to the beginner to point out some of their chief features.

While Francis Galton's "Hereditary Genius" of 1869 shows the influence of the work of Quetelet, his "Natural Inheritance" of 1889 is probably the first book published in which the modern student can find any consistent comprehensive explanation of the statistical methods as applied to biological problems. While this classic should be familiar to every statistician, it is not suitable as a guide to the beginner, for the formulæ there described have been replaced by those better suited to the practical routine of calculation.

Among the earlier treatises on the new statistics—speaking now of introductions and guides, not of original work—may be mentioned those of Duncker¹ and Davenport² written from the standpoint of methods and the volume of Vernon³ prepared more as a

¹ First suggested in 1912 by Gutherz but rejected by him.

² Duncker, G., "Die Methode der Variationsstatistik," *Archiv. f. Entwicklungsmechanik d. Organismen*, Vol. VIII, pp. 112-183, 1899.

³ Davenport, C. B., "Statistical Methods with Special Reference to Biological Variation," New York, 1899, second ed., 1909.

⁴ Vernon, H. M., "Variation in Animals and Plants," New York, 1903.

summary of progress in the study of variation, but giving some elementary explanations of methods.

Of more recent works those of the greatest value have appeared in the English language. It would have been too much to expect that the influence of the newer work would extend as far as Madrid and affect the "Tratado Elemental de Estadística" of Menguez y Vicente (1907) but something better might have been expected of France and Germany. How backward they are can be seen from such essays as Žizák's "Soziologie und Statistik," München und Leipzig, 1911, or those in the "Festschrift" for Georg von Mayr, "Die Statistik in Deutschland nach ihrem heutigen Stand," München und Berlin, 1911. Such works as F. Faure's "Elements de Statistique" and Maciejewski's "Nouveau Fondements de la Theorie de la Statistique" (1911) have, in spite of their attractive titles, no practical value to the biologist—or, as far as the present reviewer can see, to any one else. Nor can anything be said in favor of Al. Kauffmann's "Theorie und Methoden der Statistik," just published (Tübingen, 1913).

Forscher's recent book⁴ seems to be a serious attempt, apparently done in almost complete ignorance or with all but a total disregard of the fundamental calculus of the English school, to obtain a better theoretical (mathematical) basis for statistical formulae. Of the soundness of the mathematical work, I am not able to judge; nor does it particularly concern us here, for practically—that is, as a tool for the man grappling with practical statistical problems—the work has little immediate value.

Turn now to introductory works which may be of value to the beginner.

Many biologists and others are very deeply indebted to the sections on Heredity, Selection and Evolution in the second edition of Pearson's "Grammar of Science" for their first knowledge of the new methods. The second

edition is out of print, but a third is being issued.

"The Primer of Statistics" (London, A. & C. Black, 1909) prepared by the Eldertons at the suggestion of Sir Francis Galton is for the general public rather than for one who hopes to prepare for investigation. King's little book⁵ although containing something of the newer methods is for the social rather than for the biological student and is far too elementary for those who wish to do research work. Elderton's book⁶ not only embodies the actuaries' viewpoint, but presupposes the actuaries' training. Thus as a *first* book it is quite beyond the depth of the average biologist, but if he is working seriously in statistics it is most helpful on his table.

That Eugene Davenport's book⁷ on breeding—with all its points concerning which the doctors in mathematics and the doctors in biology will disagree—is a pretty good introduction for a certain class of readers is perhaps sufficiently established by the influence which it has evidently exerted in our agricultural institutions. One recognizes the scissors and paste nature of the volume, but this characteristic it shares with practically all the other introductions to statistical methods: the compilation is only a little more obvious and the compiler distinctly more honest in the acknowledgment of original sources than is sometimes the case.

Thorndike⁸ several years ago prepared an introduction for the use of psychologists which has recently (1913) been issued in a much-amplified second edition. The work is more elementary and far more verbose than the book by Brown.⁹ For this reason, Thorndike's text

⁵ King, W. I., "Elements of Statistical Method," New York, Macmillan, 1912. Cf. SCIENCE, N. S., Vol. 36, p. 519, 1912.

⁹ Brown, W., "The Essentials of Mental Meas-

⁴ Forscher, H., "Die Statistische Methode als Selbständige Wissenschaft. Eine Einführung in deren Fundamente und Grundzüge," Leipzig, 1913.

is better as an introductory work for most American students, while Brown's more technical and more comprehensive book is indispensable to those who care to do really serious research. In this connection the work of Urban¹⁰ may also be mentioned.

The most comprehensive text on modern statistics—an introduction to statistical theory rather than a guide to the application of statistical analysis in any particular field—is that of Yule,¹¹ who has brought to his task the training of an assistant in Karl Pearson's laboratory. To all those who must use statistical formulæ without being able to read with ease the fundamental papers—and this comprises all but a handful of the workers—Yule's book is indispensable. The simpler statistical processes are all treated with care and clearness, and with a terseness refreshing after the verbiage of works written from the biological viewpoint. One must commend the careful system of cross reference, which should greatly facilitate the use of the book, and the very complete and annotated bibliography which should inspire the student to study original sources. The student, moreover, should remember that even Mr. Yule's book does not render this unnecessary, for in the text some subjects of great importance are not treated at all. For example, one misses a discussion of Pearson's various types of frequency curves which have been used with such success for the past several years in describing a great variety of phenomena. The classical fourfold correlation method is also omitted. The most flagrant fault of the book is the putting forward of certain measures of association and correlation, which are worthless,¹² but which, because of their simplicity, are likely to be widely used

urements,"¹³ Cambridge University Press, 1911.

¹⁰ Urban, F. M., "The Application of Statistical Methods to the Problems of Psycho-Physics," Philadelphia, 1908.

¹¹ Yule, G. U., "An Introduction to the Theory of Statistics," London, Chas. Griffen and Co., 1911, 2d edition later.

¹² See Heron, *Biometrika*, Vol. 8, pp. 109-122, 1911; K. Pearson and D. Heron, *Biometrika*, Vol. 9, pp. 159-315, 1913.

by those who prefer ease of calculation to correctness of result.

The guides which are available the beginner must use: but he should know that there is not only no royal road, but as yet no Baedeker, to statistical analysis. Here, as is wont to be the case with text-books, the guides have for the most part been written by men who have not distinguished themselves by exploration into the territory through which they now propose to lead others. The real student will, therefore, be vigilantly skeptical, and will go as far as he is able to the original sources to read and weigh for himself.

Taking the books mentioned in this review as a class, the greatest criticism that can be made is not that there are blunders in statement and misprints in formulæ, but that throughout there is an incautious attitude towards the real difficulties which the student is to encounter, or even a positive assurance that dangers are only apparent. Nothing could be farther from the truth, for in higher statistics innumerable pitfalls surround the investigator. Serious harm has been done by telling the beginner that he need not understand the formulæ to use them. Neither is it necessary for a chemist to understand his reagents! To be sure, most of us have of necessity to work with but little knowledge of the mathematics which lie back of the formulæ, but it is the obvious duty of the student who proposes to use these newer tools of research to learn all that he can concerning the assumptions upon which the formulæ rest in order that he may apply them with intelligence.

Finally, the beginner must realize that it is as impossible to gain a working knowledge of statistical methods from a text-book without experience in the routine of measurement, computation and interpretation as to acquire proficiency as an organic chemist outside the laboratory. It takes years of hard work to make a proficient biometrician—although some have to their own satisfaction qualified for the writing of texts much more easily.

J. ARTHUR HARRIS

THREE TEXT-BOOKS IN BIOLOGY

The Principles of Biology. By J. I. HAMAKER. Philadelphia, P. Blakiston's Son & Co. 1913. 8vo. Pp. x+459. 267 illustrations.

Within the brief space of 438 pages, the author of this little volume has condensed a large amount of accurate information. As is stated in the preface, the book has been prepared as a substitute for the lecture notes of the ordinary pupil and of its superiority over such sources of information, or misinformation, there can be no doubt. After a very brief introduction, there follows over a hundred pages on plant biology and over three hundred on animals. Brief laboratory directions are included and a great variety of subjects are dealt with. A general review of plant physiology is followed by an account of the classes of plants and a consideration of their ecology. In a similar way the general physiology and morphology of animals is followed by a description of the classes of the animal kingdom. The whole account is concluded by an interesting section on general principles such as the structure of the cell, embryology, origin of species, adaptations, etc. In fact the list of headings at once indicates the scope and shortcomings of the book, for with so much to be covered and with so little space in which to do it, much of the treatment is necessarily abridged and inadequate. Yet as a condensation the volume has many points in its favor. The illustrations are often very good, particularly some of those taken from photographs of the original objects.

Elementary Biology. Plant, Animal, Human.

By J. E. PEABODY and A. E. HUNT. New York, The Macmillan Company, 1913. 8vo. Pp. xxi+170+194+209. Over 300 illustrations.

This volume is avowedly intended for high schools and covers those parts of botany, zoology and a study of the human being that are most worthy of emphasis. The general structure and physiology of plants is first dealt with, then their relation to human welfare, and finally their classification. Under animal biology chapters are devoted to insects, birds, frogs, fishes, crayfishes and their allies, and the

one-celled animalcules. The remaining groups of the animal kingdom are briefly considered in a final chapter. The section on man is mostly concerned with his physiology. The chapter on stimulants and narcotics is particularly to be recommended in contrast to similar chapters in the older school physiologies. There is an appendix that contains many useful suggestions to the teacher and the volume is concluded by a good index. Most of the illustrations are excellent, but in Fig. 26 the size of the head in comparison with that of the viscera is quite misleading and Fig. 99 is unnecessarily crude. It is to be regretted that the three sections of which the book is composed should have been separately paged and their figures separately numbered. It is difficult to see how this can be anything but an inconvenience unless it is intended to allow the publisher to divide the book easily into its three separate parts.

An Introduction to Zoology. By R. LULHAM.

London, Macmillan and Co., Limited, 1913. 8vo. Pp. 457. 328 illustrations.

This volume is on most conservative lines even to the classical quotation preceding the introduction. It takes up in methodical fashion group after group of the invertebrates and thus includes an account of all the chief divisions of the lower animals. The author believes there is place for such a compact volume as this and that it should be read by those pupils who spend much of their time in the laboratory. The book is like so many that have been published in the last decade that it carries scarcely the air of novelty. In a reading text such as this it is unfortunate that so interesting and important a group as the chordates should have been intentionally omitted. For originality of treatment and an air of modernity this volume is much behind the other two already noticed.

G. H. PARKER

THE ATOMIC WEIGHT OF LEAD OF RADIO-ACTIVE ORIGIN

THE atomic weight of lead obtained from radioactive minerals has recently been studied

by Professor Theodore W. Richards, of Harvard University, and Mr. Max E. Lambert, who came to America from the Grand Ducal Technical School of Karlsruhe for this purpose, on the initiative of Professor Bredig and Dr. Fajans. The latter well-known investigator, as well as Sir William Ramsay, Professor Boltwood, Miss Gleditsch and Mr. Miner generously provided the experimenters with residues containing lead of this sort. It was found that all the lead obtained from uraninite, carnotite or thorianite exhibited a lower atomic weight than ordinary lead, the deficiency amounting in one case to as much as 0.75 unit. The ultra-violet spectrum of a typical specimen appeared to be exactly identical with that of ordinary lead. The necessary inference seems to be that lead from radioactive sources consists of a mixture of at least two substances, of which one is ordinary lead. The foreign substance must be very similar to ordinary lead and very difficult if not impossible to eliminate by chemical means; for many precautions were taken to purify the samples. This amazing outcome is contrary to Harvard experience with several other elements, notably copper, silver, iron, sodium and chlorine, each of which has been found to have a constant atomic weight, no matter what the source may have been. The new results on radioactive lead are qualitatively in accord with a recent hypothesis brought forward independently by Fajans, by Russell, and by Soddy, although quantitatively not exactly consistent with it. A preliminary paper, setting forth the detailed methods and results, was sent to press on May 14, and will appear in the July number of the *Journal of the American Chemical Society*. The research was generously subsidized by the Carnegie Institution of Washington.

SPECIAL ARTICLES

THE PRODUCTION OF MALES AND FEMALES CONTROLLED BY FOOD CONDITIONS IN *HYDATINA SENTA*

THE factors that regulate the production of the sexes in the rotifer *Hydatina senta*

have been zealously sought for during the past twenty-five years and various results have been obtained. Temperature, starvation of the young females, unknown external agents, and finally the intangible unknown internal factors, have been decided to be the potent influences that regulate the sex ratio in the parthenogenetic reproduction.

Mitchell¹ has recently experimented with the rotifer *Asplanchna* and has found that a sudden change of the food will bring about the production of a certain one of the polymorphic forms of this rotifer. This particular form of the female produces males. He therefore concludes that a change of food eventually causes male individuals to be produced. He suggests that this food factor may be found to regulate the sex production in *Hydatina senta*.

Some time ago it was shown by Whitney² that uniform food conditions caused a production of only females for 289 generations in *Hydatina senta*. Since that time many attempts have been made to find some food conditions that would cause the females to produce only male offspring. Many kinds of mixed cultures of various protozoa have been tried as food and a varied assortment of results have been obtained. This winter pure cultures of several species of protozoa have been grown and more definite results have been obtained. Several kinds of colorless flagellates as well as several kinds of green flagellates were reared and used as food for *Hydatina senta*. Some were tried as a continuous diet and others were used in an interrupted diet. The colorless flagellate, *Polytoma*, was found to be the most satisfactory as a continuous diet for producing only female offspring. A species of the green flagellate *Dunaliella* (Teodor) or *Chlamydomonas* (Cohn) was found to be the most effective in causing the females to produce a high percentage of male offspring by an interrupted diet.

Some fertilized eggs were taken in November from a covered culture jar of rotifers that

¹ *Jour. Exper. Zool.*, Vol. 15, August, 1913.

² *Biol. Bull.*, Vol. 22, 1912.

was made in 1908 and had been standing unchanged since that time. A general new culture of rotifers was made from these fertilized eggs and then a few females were selected at random and fed upon a continuous diet of the colorless *Polytoma* in watch glasses. After a few generations a very high percentage of females were produced. At this period adult females were taken from several of the watch glasses and placed in some filtered water from a jar in which a general culture of rotifers were thriving. Then there was added to this culture water the green flagellate, *Dunaliella*.

ous diet of *Polytoma* to a diet of the green *Dunaliella*.

Several other green flagellates have been reared and used as food, but they do not seem to be effective in causing males to be produced. Many other observations are being made in a further study of the problem, and the detailed results together with the exact methods used will be published in a later paper.

D. D. WHITNEY

BIOLOGICAL LABORATORY,
WESLEYAN UNIVERSITY,
MIDDLETOWN, CONN.

Experiment	Continuous Polytoma Diet				Adult Females taken from Cultures that had been Living on a Continuous Diet of <i>Polytoma</i> , a Colorless Flagellate, for Several Generations and Put upon a New Diet, the Green Flagellate, <i>Dunaliella</i>																		
	Control				Lot A		Lot B		Lot C		Lot D		Lot E										
	Adult Females	Daughters	Per Cent. of ♂'s	Per Cent. of ♀'s	Adult Females	Daughters	Adult Females	Daughters	Adult Females	Daughters	Adult Females	Daughters	Adult Females	Daughters	Adult Females	Daughters							
1	5	52	9+		5	50	78		5	47	80+		5	54	75+		5	60	80		5	54	
2	5	60	3+		5	51	83+		5	50	74		5	56	82+		5	54	81+		5	54	83+

The controls were also placed in this filtered culture water and the colorless flagellate *Polytoma* was added.

The above table giving the details of two experiments shows the decided and striking results obtained. The continuous diet of *Polytoma* caused the adult females to produce 6+ per cent., as an average, of daughters that were male-producers, while the diet of the green *Dunaliella* that was given to the other adult females caused them to produce as an average 79+ per cent. of daughters that were male-producers.

These experiments are not exceptional, but are only two from many others already completed that are equally as good as these and which were obtained in a series of successive experiments. In all other experiments during the last eight years on *Hydatina senta* there has occurred from time to time a sudden production of males, but such experiments never could be repeated with equal success. Now the male-producing females can be caused to appear at any time from any stock in the laboratory by the sudden change from a continu-

³ Females which produce male offspring.

THE AMERICAN PHILOSOPHICAL SOCIETY

THE annual general meeting of the American Philosophical Society was held in the rooms of the society in Philadelphia, April 23 to 25 inclusive, and constituted a most interesting series of sessions. There was a large number of papers presented, their general character being of a high order of merit and the scope of subjects included being wide.

The meeting was opened on Thursday afternoon, President W. W. Keen, LL.D., in the chair, when the following papers were read:

The Physical Cause of the Unsymmetrical Equilibrium of the Earth Between the Land and Water Hemispheres, with a Theorem on the Attraction of the Terrestrial Spheroid: T. J. J. SEE.

Some Observations on the Psychology of Juries and Jurors: PATTERSON DU BOIS, Esq.

Factors of Influence in the Origin and Circulation of the Cerebro-spinal Fluid: CHARLES H. FRAZIER.

Aspects and Methods of the Study of the Mechanism of the Heart Beats: ALFRED E. COHN. (Introduced by Dr. Keen.)

Interest in the mechanism of the heart-beat was stimulated by the discovery that the electric currents which the heart discharged during contraction could be registered by a moderately sensitive, but rapidly reacting galvanometer. A general use of such galvanometers was introduced in 1906-08. At the same time structures dealing with impulse formation (the sino-auricular node of Keith and Flack) and conduction (the auriculo-ventricular node of Aschoff-Tawara and the auriculo-ventricular bundle of Kent and His, Jr.) in the heart were discovered. These discoveries form the basis of contemporary studies.

The various waves which are found in the electrocardiogram, which is the name given to the photographed curves of the cardiac action currents, have been identified as representing definite events in the cardiac cycle. The validity of electrocardiograms as records has been established, not only for different classes of animals, but for species as well. So far as man is concerned, records can be differentiated as between individuals, and the record of the individual recognized over long periods of time as peculiarly his own. This individuality of records applies not only to normal, but also to abnormal conditions.

Alterations in the established form of electrocardiograms occur, and the conditions which cause a number of the changes were described. Most of these conditions depend on changes within the structure of the heart, while others on the physical relation of the heart to the body of the individual. Finally, a number of observations indicating the value of the galvanometric method in studying the control of the central nervous system over the heart were presented.

The Kinetic System: GEORGE W. CRILE.

Animals are transformers of energy. Adaptation to environment is made by means of a kinetic system of organs evolved for the purpose of converting potential energy into heat and motion. The principal organs comprising the kinetic system are the brain, the thyroid, the suprarenals, the liver and the muscles. The brain is the great central battery which drives the system, the thyroid governs the conditions favoring tissue oxidation; the adrenals govern immediate oxidation processes; the liver fabricates and stores glycogen; and the muscles are the final means by which the latent energy is converted into heat and motion. The positive evidence regarding the response made by these organs to various forms of stimulation contained in a large amount of experimental data

is verified by the negative evidence that the power of the body to convert latent into kinetic energy is impaired or lost when the brain, the thyroid, the suprarenals, the liver or the muscles are impaired.

Clinical as well as experimental evidence shows that any change in any link of the kinetic chain modifies the entire kinetic system proportionately. Such a change may result in an immediate breakdown—acute shock; or else the gradual modification of one or more of the kinetic organs may give rise to a number of diseases. This theory has already given us the shockless operation and it opens a possibility of controlling certain chronic diseases which are the result of overstimulation of one or more of the organs in the kinetic chain.

The Hereditary Basis of Certain Emotional States: CHARLES B. DAVENPORT.

Syriac Socrates—A Study in Syrian Philosophy: W. ROMAINE NEWBOLD.

The speaker argued that this dialogue, which has been entirely neglected since its publication in 1858, represents a philosophical system so intimately related to that of Bardaisan of Edessa, that it must be regarded as written either by him or by some member of his school.

The Evolution of Pine Barren Plants: JOHN W. HARSHBERGER.

*Segregation of "Unit Characters" in the Zygote of *Eurothera* with Twin and Triplet Hybrids in the First Generation:* GEORGE FRANCIS ATKINSON.

The segregation of "unit characters" is a phenomenon now widely and well known, particularly as it relates to Mendelian segregation, with the production of different hybrid types in the second generation. But the segregation of several distinct hybrid types in the first generation of a cross between two species is a rare phenomenon. The fundamental distinction between these two types of segregation is apt not to be appreciated at once, since we are so accustomed to think in terms of Mendelian segregation.

Further, in Mendelian segregation, the production of "dihybrids," "trihybrids," etc., according to the number of contrasting allelomorphs in the parents, is so familiar that it requires some special emphasis for the mind to grasp how fundamentally different "twin hybrids" are from dihybrids, "triplets" from trihybrids, etc.

In the experimental studies here briefly outlined the two parents are *Eurothera nutans* and *E. pycnocarpa*, wild species of the evening primrose

in the vicinity of Ithaca, N. Y. They differ by more than thirty easily recognizable contrast pairs of "unit characters," or allelomorphic pairs, or, in terms of the "presence and absence" hypothesis, there are more than sixty "factors" of recognizable characters which meet in the fertilized egg of the cross between the two parents. These characters relate to the habit and color of the adults; features of the rosettes, foliage and inflorescence.

When *pycnocarpa* is the mother two distinct hybrid types are segregated in the first generation, and have been brought to maturity. These are *twin hybrids*. When *nutans* is the mother the same twin hybrids appear, and in addition a triplet which at present is in the rosette stage.

An analysis of the hybrids shows a distinct linking, or association, of certain characters. The bond between these characters is stronger than that of the total composition of either parent, and in the case of certain characters stronger than the total composition of certain organs or members. This results in a splitting of the total composition of both parents, and also a splitting of the total composition of certain members of the plant body. Examples of this linking of characters are as follows: First, habit characters; second, color characters; third, petal characters; fourth, broadness and toothedness of rosette leaves; fifth, narrowness and cutness of rosette leaves; sixth, crinkledness, convexity and red-veinedness of rosette leaves; seventh, plainness, furrowedness and white-veinedness of rosette leaves.

This splitting of the parental constitution resulting in the segregation into twin and triplet hybrids in the first generation occurs in the zygote or fertilized egg. Therefore it is of a very different type from that which takes place in Mendelian segregation due, according to general belief, to a qualitative, or differential division or reaction, in the gonotokonts (mother cells of the pollen grains and embryo sac). No such qualitative division is known to take place regularly in the fertilized egg. Therefore the usual karyokinetic process in the first division of the zygote can not be invoked in an interpretation of segregation of "unit characters" in the fertilized egg. The following hypotheses are considered.

First. De Vries's hypothesis of twin hybrids from mutating species. It does not appear probable, in the case of the two species considered here, that the segregation is due to the mutating character of one parent with its consequent spliability of constitution, combined with the splitting power of the constitution of another non-muta-

ting parent, which is de Vries's interpretation of twin hybrids in the first generation of a cross between *Oe. lamarkiana*, or certain of its mutants, and a wild non-mutating species.

Second. Theory of a differential division in the zygote. The meeting, in the fertilized egg, of such a large number of homologous, but contrasting, "qualities" or "bearers," may be less favorable for a blending of the contrasting members of a pair, than for some other combination. The different positions which the linked "factors" or "qualities" occupy as they approach the nuclear plate of the first division may well be due in a large measure to chance. In this way different combinations might establish a working relation in different eggs. The material representing the groups of characters not entering into any one working combination may then be left behind in the first suspensor cell of the embryo, or cast out into the cytoplasm. The material in the first suspensor cell plays no part in the formative processes of the new individual, since this cell is side-tracked by the basal wall formed during the first division of the zygote.

Third. The reaction theory. In view of the fact, which seems to be now quite well established, that certain hereditary qualities are governed by enzymatic action, it may not be improbable that all the factors, or bearers, may work through enzymatic or catalytic or other chemical processes. But when the substances mixed are alike in all cases, and the conditions are the same, it is not intelligible, from a chemical point of view, why in some eggs one reaction should take place, while in others the reactions should be totally different. Even if we accept in principle the reaction theory, the different reactions taking place in different hybrid eggs seem to point to a differential division or segregation of material portions or regions of the hybrid egg cell.

The Vegetation of the Sargasso Sea: WILLIAM G. FARLOW.

The Sargasso Sea through which Columbus passed on his first voyage to America is characterized by the scattered masses of gulf weed which float on the surface of the ocean in patches generally from fifty to a hundred feet in diameter. The question as to the origin of the gulf weed has never been definitely settled. Some consider that the gulf weed whose botanical name is *Sargassum bacciferum* is merely a mass of sterile branches of some species of *Sargassum* which grows attached in the region of the West Indies

and fruits. Others believe that in its present floating form the gulf-weed is a distinct species which has lost the power of fruiting and increases only by offshoots. In recent years the species of *Sargassum* growing in different parts of the West Indies have been more carefully studied and a comparison with the floating gulf-weed shows that mixed with the latter are found in small quantity fragments of at least two species known to grow in the West Indies. In only one instance has there been found mixed with the gulf-weed a seaweed which must have come not from the American coast, but from Africa or southern Europe.

In spite of the fact that most recent writers consider the gulf-weed as a distinct species, there is reason to think that it is really derived from some *Sargassum* growing in the West Indies, fragments of which are carried by the Gulf Stream to the Sargasso Sea. There are, however, still many doubtful points to be settled.

THURSDAY EVENING, APRIL 23

Meeting of the Officers and Council

At 8:30 O'clock

FRIDAY, APRIL 24

Executive Session—9:30 o'clock

Proceeding of the officers and council submitted.

Morning Session—9:35 o'clock

Albert A. Michelson, Ph.D., Sc.D., LL.D., F.R.S., Vice-president, in the chair.

Phase Changes Produced by High Pressures:
PERCY W. BRIDGMAN. (Introduced by Professor Goodspeed.)

The packing and the form of apparatus were described with which it has been possible to reach high pressures. These pressures have been pushed as high as 30,000 or 40,000 kgm. per sq. cm., or 15 or 20 times as high as that in modern artillery. The methods were then described by which it is possible to tell when a liquid is frozen to a solid or one solid changed into another by the application of pressure. One of the problems of particular interest is as to the character of the melting curve. There have been theories proposed, but hitherto sufficient pressure has not been obtainable to submit these theories to experimental test. Examination of the melting of a number of liquids over a wide pressure range has shown that the theories hitherto proposed do not hold at high pressures. The fact seems to be that as far as we can judge the melting curve con-

tinues to rise indefinitely, so that a liquid may be frozen by the application of sufficient pressure, no matter how high the temperature. A number of results are also obtained for the reversible transition from one crystalline form to another. Several new solid forms have been obtained; of particular interest are the new forms of ice, which are denser than water. In addition to these changes, which are completely reversible, one example has been found of an irreversible reaction produced by high pressure; yellow phosphorus may be changed by 12,000 kgm. and 200° to a modification in appearance like graphite, which is 15 per cent. more dense than the densest red phosphorus.

The Influence of Atmospheric Pressure on the Forced Convection of Heat from Thin Electric Conducting Wires: ARTHUR E. KENNELLY.

Some New Tests of Quantum Theory and a Direct Determination of "h": ROBERT ANDREWS MILLIKAN. (Introduced by Professor Goodspeed.)

It has been known for 25 years that when light of sufficiently short wave-length, i. e., of sufficiently high frequency, falls upon a metal, it has the power of ejecting electrons from that metal.

It has been known for seven years that the kinetic energy possessed by the electrons thus ejected is larger the higher the frequency of the light which ejects them. In other words, blue light throws out electrons with greater speed than does red light.

Whether or not the energy of ejection is directly proportionate to frequency has been a matter of some uncertainty and of considerable dispute up to the present time.

The work herewith presented furnishes in the first place the most conclusive proof which has yet been found that there is exact proportionality between the energy of the ejected electrons and the frequency of the light which ejects them.

The second and most important contribution which it makes is the proof, given here for the first time, that the factor of proportionality between the energy of the ejected electrons and the frequency of the incident light is exactly the same quantity which has figured so largely in the recent developments of theoretical physics, namely, the fundamental constant which appears in Planck's theory of the discontinuous or explosive character of all radiant energy of the electromagnetic type. This constant is known as Planck's "*h*," and its value is directly deter-

mined in this work with an error which does not exceed one per cent. The value found is in very close agreement with that obtained by other methods. It is probable, however, that none of these other methods are capable of as high a precision as the photo-electric method here used.

The discovery that an electron ejected from a body under the influence of mono-chromatic light acts as though the whole energy content of the light wave were transferred without loss to the electron has important bearing on the whole framework of theoretical physics. It constitutes a new triumph of Planck's atomistic theory of radiation or, better, perhaps, a new proof of the usefulness in a new domain of Planck's "*h*."

The full theoretical significance of the mass of facts connected with "*h*," which have come to light within the past three or four years has not, however, as yet been fully discerned.

Discussion of "A Kinetic Theory of Gravitation"

—(1) *Gravitation is Due to Intrinsic Energy of the Ether*; (2) *Transmission of Gravitation can not be Instantaneous*: CHARLES F. BRUSH.

A kinetic theory of gravitation was outlined by the author at the Minneapolis meeting of The American Association for the Advancement of Science,¹ in which the ether is assumed to be endowed with vast intrinsic kinetic energy in wave form of some sort capable of motive action on particles, atoms or molecules of matter, and propagated in every conceivable direction so that the wave energy is isotropic. Particles or atoms are imagined to be continually "buffeted in all directions by the ether waves like particles of a precipitate suspended in turbulent water. There are no collisions because neighboring particles follow very nearly parallel paths. Each atom or particle is regarded as a center of activity due to its energy of translation initially derived from the ether; whereby it has a field of influence extending in all directions, or casts a spherical energy shadow, so to speak. The energy shadow of a body of matter is the sum of the shadows of its constituent parts. The energy shadows of two gravitating bodies interblend, so that the energy density between them is less than elsewhere, and they are pushed toward each other by the superior energy density or wave pressure, on the sides turned away from each other.

In the present discussion the author employs some impressive illustrations to show that the energy acquired by falling bodies has some ex-

ternal source, and that it must be ethereal energy or energy of space; and he holds that the term "potential energy of position," as applied to a system of gravitating bodies implies the energy-endowed ether as a necessary part of the system.

As a corollary, the author explains how bodies falling toward each other by reason of their mutual attraction, and thus *accelerating*, that is to say, absorbing energy from the ether, can not rigidly obey Newton's law of inverse squares of distance. The force of attraction instead of varying as $1/D^2$, as it does for bodies at rest or in uniform motion, varies as $1D^{(2-\alpha)}$ for bodies accelerating in the line of attraction, wherein α is a very small quantity which appears to vary with the rate of energy transformation or velocity of fall. When acceleration is negative, that is to say when energy transformation is *from* the accelerating body to the ether, α becomes positive.

In the case of a planet of the solar system, α obviously increases in importance with eccentricity of orbit, and may become appreciable in the highly eccentric orbit of Mercury. The author expresses the hope that this alternately plus and minus deviation from Newton's law will be found adequate to explain the secular advance of the perihelion of Mercury's orbit. He also calls attention to the fact that the moon moves toward and away from the sun almost the whole diameter of her orbit every month, and hopes that, in this connection, the deviation from Newton's law above indicated may explain the outstanding lunar perturbations, and perhaps cancel another to be mentioned later.

In the second division of the paper the author describes the premises from which Laplace drew his famous conclusion that gravitation is transmitted with infinite, or virtually infinite, velocity; a dogma which "for more than a century has blocked the path of fruitful thought on the physics of gravitation." The radically different premises growing out of the theory under discussion are then described and contrasted with those of Laplace, to explain why and how the author reaches such a widely different conclusion. He concludes that, even if the velocity of transmission is no greater than that of light, the moon's mean motion will be *retarded* a very few seconds of arc only, in a century; and the retardation will be correspondingly less if the velocity is greater than that of light. This retardation, of course, adds to the unexplained acceleration, if any, of the moon's motion; but the author further hopes that this retardation, plus the outstanding acceleration,

¹ SCIENCE, March 10, 1911; *Nature*, March 23, 1911.

will be explained by the deviation from Newton's law already described.

Behavior of Metals and Other Substances under Stress Near the Rupture Point: A. A. MICHELSON.

On Highly Radioactive Solutions: WILLIAM DUANE. (Introduced by Professor Goodspeed.)

At the annual meeting last year the author spoke on "Some Unsolved Problems in Radioactivity." At that time he stated that a number of superficial cancers had been cured (some of them only temporarily) by the proper application of a sufficient quantity of radium, but that the problem of treating internal cancers had not been satisfactorily solved. There appears, he said, to-day to be no reason for changing that statement.

Since that meeting the Cancer Commission of Harvard University has purchased about 250 milligrams of radium element, and has been investigating the effects due to the rays from radioactive substances on tissues, using methods that the author has devised and that are somewhat different from those employed before. He dwelt particularly on one of these methods, namely, that in which a concentrated radioactive solution is injected into the tissues.

Before describing the experiments he recalled the following well-known facts. Firstly: radium is continually transforming itself into a gas called radium emanation, and this emanation is continually transforming itself in turn into a succession of substances called radium A, B, C, etc., which are grouped together under the general term "deposited activity." These substances are radioactive as well as the radium itself. Any sealed glass tube containing radium contains these other radioactive substances also.

Secondly: these substances emit three types of rays, the alpha, beta and gamma rays. The alpha rays carry with them about 90 per cent. of the energy of the radiation, and the other 10 per cent. is divided between the beta and gamma rays. The alpha rays, however, are the least penetrating of the three types; they are stopped by about 1/25 of an inch of ordinary flesh.

Thirdly: radium, the emanation and radium A practically emit alpha rays only. Radium B emits weak beta and gamma rays and no alpha rays; but radium C emits all three kinds and is by far the most powerful radiator of the whole group. In the ordinary application of radium to tumors the methods are of such a nature that the alpha rays are absorbed before they reach the tissues, and the beta and gamma rays, therefore, are the only

ones used. Hence over 90 per cent. of the energy is wasted; and further the rays that are used come exclusively from radium B and C, and not from the radium itself or from the emanation.

The emanation and deposited activity can be separated from the radium and used alone. The method the author has perfected for doing this is as follows: The radium salt itself is in solution in a small glass tube, from which the air has been completely exhausted. Under these circumstances the emanation escapes from the solution. A simple mercury pump pumps the emanation into a second tube containing phosphor pentoxyl and a copper wire heated red hot by an electric current. The hot wire absorbs the hydrogen and oxygen that have been produced by the decomposition of the water, and the pentoxyl absorbs the water vapor. After purification a second pump pumps the emanation into a small glass bulb containing a few grains of common salt. The emanation remains in contact with the salt for several hours, depositing radium A B C on it. The salt thus becomes very radioactive, and on being removed from the bulb and dissolved in a small amount of water carries with it the activity, thus making the solution itself radioactive.

He has used several other methods of making these radioactive solutions. The deposited activity may be deposited on sodium hydroxide, and this may be dissolved in a few drops of water containing just enough hydrochloric acid to neutralize the hydroxide; or the emanation may be sealed into a small glass bulb with a capillary glass tube attached. If this is placed under water or a saline solution and the capillary tube broken, the liquid runs up into the bulb and dissolves the emanation, forming a radioactive solution. Solutions made by these methods may be millions of times more active than those hitherto used. In fact, they may be made weight for weight far more active than any solution containing radium itself could be.

The advantage in using these solutions in studying the effects produced on tissues is that after injection the radioactive substances come into intimate contact with the tissues, and thus the full power of the alpha rays is utilized.

If a solution of radium itself is injected, the process is not only costly, but very dangerous on account of the long life of the radium. The deposited activity solutions do not have these objections, for the radium is not wasted in producing the solutions and the activity lasts for only a short time.

He made a number of experiments to find out

where the radium A B C goes to after the injection. The injection is absolutely painless. If the injection is made subcutaneously a large fraction of the activity remains in the neighborhood of the point of injection, and the rest is carried off in the lymph and blood streams. The rapidity with which the activity gets into circulation is astonishing. A drop of blood taken from another part of the body only a few seconds after the injection is more radioactive than carnotite or pitchblende ores. It would seem that this might prove to be a delicate method of studying the flow of fluid through the tissues.

On making tests by means of the gamma rays an hour or an hour and a half after the injection he found that there was very little activity in the brain and lungs, but that there was a tendency for the substances to deposit out in the liver, spleen and kidneys.

Histological examinations were made by Dr. E. E. Tyzzer, who found a marked destruction of the bone marrow and of the leucocytes. Further, if the injection is made either into the tumor or the veins of a mouse with a tumor there is a decided destruction of the tumor cells.

Some Further Considerations in the Development of the Electron Conception of Valence: K. G. FALK. (Introduced by Professor Bogert.)

The Valence of Nitrogen in Ammonium Salts: WILLIAM ALBERT NOYES. (Introduced by Professor H. C. Jones.)

The specific rotation of solutions of aminocamphonan and of aminodihydrocampholytic acids have been determined, also the rotations of the anhydrides, hydrochlorides and sodium salts of these acids. A comparison of these rotations furnishes strong evidence that the free aminocamphonan and the aminodihydrocampholytic acids exist in the form of cyclic salts, containing a ring of six atoms and nitrogen in the quinquivalent form. The α -aminocampholic and β -aminocampholic acids, on the other hand, as indicated by the rotation of their solutions, do not form such cyclic salts, probably because the salts, if formed, would contain a seven-atom ring. The study of these compounds furnishes considerable evidence that nitrogen is in reality quinquivalent in ammonium salts and that such salts are not merely addition compounds formed by the union of the acid with the amino compound in such a manner that each molecule retains its original structure.

Determination of the True Atomic Weight of Radium: GUSTAVUS HINRICHS.

FRIDAY, APRIL 24

Afternoon Session—2 o'clock

Edward C. Pickering, D.Sc., LL.D., F.R.S., Vice-president, in the chair.

Presentation of a portrait of the late Samuel Pierpont Langley, LL.D., a former vice-president of the society, by Cyrus Adler, A.M., Ph.D., on behalf of a number of members of the society.

The Magnetic Phenomena of Sun-spots; The General Magnetic Field of the Sun: GEORGE E. HALE. (Illustrated with lantern slides.)

Summary of Researches, Department of Terrestrial Magnetism, 1904-14: LOUIS A. BAUER. (Illustrated.)

On the Colors of the Stars in the Cluster M 13: EDWARD E. BARNARD.

The Use of a Photographic Doublet in Cataloguing the Position of Stars: FRANK SCHLESINGER.

The Distribution in Space of 90 Eclipsing Stars: HENRY NORRIS RUSSELL.

The Eclipsing Variable Stars ψ Orionis and 88 d Tauri: HARLOW SHAPLEY. (Introduced by Professor H. N. Russell.)

Some Features of Moon's Motion and a Problem in Isostasy: ERNEST W. BROWN.

The United States as a Factor in World Politics: LEO S. ROWE.

After an analysis of the circumstances that have made the United States an important factor in world politics, Dr. Rowe proceeded to discuss the lack of adjustment between the international position of the United States and the national thought of the American people. The country has advanced to the rank of a world power, but the standards of public opinion with reference to international affairs have failed to make a corresponding advance. In discussing the situation, the speaker said:

We are at the present moment witnessing one of the most serious consequences of this lack of adjustment which is affecting the international position and influence of the United States to a degree which can not help but arouse the grave concern of every thoughtful and patriotic citizen. In a brief period of fifteen years we seem to have sacrificed the position of leadership in the maintenance of world peace, and have become one of the disturbing factors in world politics. How is it, it will be asked, that a nation which through the contributions of more than a century has gained an enviable position as a leader in the great movement for the advancement of international good-will, a nation whose founders dreamed of a period of uni-

versal peace, should within so short a space of time sacrifice this enviable position and come to be looked upon by all nations of western civilization as an uncertain factor in the orderly development of international relations?

Every student of international law and of world politics has been deeply impressed by the important part played by the United States, in placing the conduct of international relations on a distinctly higher plane. It seems, at first glance, extraordinary that during the first half century of its national existence a nation so weak and in many respects so unorganized should have been able to exert so important an influence on international law. When, however, we stop to reflect that during the first decades of the nineteenth century the United States held the balance of power, the apparent paradox is really explained.

The far-seeing statesmanship of the founders of the republic led to the adoption, as a cardinal principle of American foreign policy, of the rule that the United States must be kept free not merely from entangling European alliances, but from any participation in the conflicts then raging in Europe. This principle of aloofness from European entanglements led to the assertion of those principles of American neutrality which, while serving primarily the interests of our national integrity, accomplished the still larger purpose of laying the foundations for the modern law of neutrality, which has done so much toward eliminating the causes of international irritation and, therefore, of promoting the interests of world peace.

It has been the laudable ambition of successive Secretaries of State to continue and to strengthen those lofty and noble traditions which gave to the country a position of such unique power amongst the nations of both eastern and western civilization. In spite of these efforts, however, there is noticeable, during recent years, a distinct falling off in our international prestige. Little by little, the confidence of the peoples of Europe and of the American continent has been undermined until today we find ourselves in a situation which possesses none of the elements of that splendid isolation which so long characterized the position of Great Britain and which, if not remedied, is likely to deprive us of the possibility of continuing a mission which constitutes the chief glory of American foreign policy during the first century of our national existence. It is, therefore, a matter of real national moment to inquire into the causes that have brought about this change, and to seek a remedy, if the elements exist.

Of the elements contributing to the present situation, some are of long standing, the cumulative effects of which are now being felt, while others are of comparatively recent development. Amidst the splendid record of achievement during the first century of our national existence there looms up one aspect in our policy which has been a source of deep concern to successive Presidents and to successive Secretaries of State. I refer to the inadequacy of our national legislation for the protection of aliens resident within our borders. A long series of massacres, beginning with the Chinese massacre at Rock Springs, Wyo-

ming, in 1895, and ending with the lynching of Italians in 1899, 1901 and 1910, have placed our national government in the humiliating position of acknowledging to foreign powers that although the sole responsibility for the conduct of our foreign relations rests with the federal authorities, they lack the power to fulfill that primary and fundamental international obligation, namely, that the persons responsible for such crimes shall be brought to justice.

It is clear that no nation can shirk the responsibilities of its international obligations without arousing widespread opposition. The constitutional authority granted to our federal government is sufficiently broad and comprehensive to include all powers necessary to meet our international obligations. We can not permit our states, which occupy no international status, to plunge us into irritating controversies with foreign countries. The dignity of the national government and the demands of national self-respect require that the federal executive be given statutory powers and that the federal judiciary be given jurisdictional authority sufficiently broad to enable the national government to do its full duty in the protection of the persons and property of aliens resident within our borders. The first step in this direction is the enactment of a law giving the federal courts jurisdiction over all cases in which the treaty rights of a citizen or subject of a foreign country are involved. A bill to this effect has been before the congress of the United States on several different occasions.

The remedy for this situation is so simple that there is no excuse for further delay in making it effective.

A second influence which has played an important part in estranging the good-will of foreign countries is the widespread belief that there exists in the congress of the United States a marked tendency to force upon the executive a narrow and technical interpretation of treaties. Secretary Hay once said of certain senators who attempted to defeat every treaty presented to the senate that their idea of a treaty was a document which gained everything for the United States and gave nothing to the other party. The ruthless way in which the congress of the United States has at times swept aside treaty obligations, and the unwillingness to bring national legislative policy into harmony with our international obligations have created the impression that the promises of the United States can not be depended upon, and that even the best intentions of the President and his advisers are apt to be thwarted by the action of congress.

The culminating point of a series of instances was reached in the provision of the Panama Canal Act exempting American coastwise shipping from the payment of Canal tolls. Whatever may be our views as to the desirability of the exemption clause viewed as a question of domestic policy, it is clear from the history of the Clayton-Bulwer and of the Hay-Pauncefote treaty and from the testimony of those who assisted in the negotiation of the latter that the United States made no attempt to reserve to itself the right to give preferential treatment to its own merchant vessels. The privileges acquired

by the United States under the Hay-Pauncefote Treaty involved certain sacrifices on the part of Great Britain, for which she exacted the observance of the principle of equality of treatment. It would be a reflection on our country's reputation for fair dealing if, after securing the abrogation of the Clayton-Bulwer Treaty, we were to repudiate the concessions, the making of which rendered possible the ratification of the Hay-Pauncefote Treaty.

Fortunately for the good name of the United States, the President has courageously taken a position, which has not only aroused the admiration of the civilized world, but has placed our country under a debt of obligation. In his address of March 5, 1914, to the congress of the United States, he sounded a note which served to impress upon the nation the sacredness of treaty obligations.

The magnitude of the President's service goes far beyond the vindication of the Hay-Pauncefote Treaty. These words and the determination which lies back of them place the international relations of the United States on a distinctly higher plane, and, if properly supported by the united opinion of the country, will do much toward regaining for the United States the enviable position which we once occupied. All secondary and party interests must be made to bow before that higher standard of international dealing which the President so vigorously champions.

Passamaquoddy Morphology: J. DYNELEY PRINCE.

The present article on the morphology of the Passamaquoddy language of Maine is the first result of the rehabilitation of my exhaustive treatise on the Maine Passamaquoddies which was destroyed by fire, together with all notes, in 1911. The Passamaquoddies of Maine, as well as their close congeners, the Micetetes of New Brunswick, are second to the Miamaes in numerical importance among the eastern Algonquin tribes. The Miamaes of Nova Scotia, the Passamaquoddy-Micetetes of Maine and New Brunswick, and the Penobscot-Abenakis of Maine and Quebec constitute the family of the Wabanaki "people of the dawn-land" whose extraordinary folklore and interesting linguistic structure have been strangely neglected. In the paper especial attention was paid to the verbal formation of the Passamaquoddy with a comparison between its forms and those of the Abenaki of Canada, and in his oral presentation of this subject Professor Prince gave a few brief specimens of eastern Algonquin folklore poems in order to illustrate the character of these Indians.

A Sumerian Nature Hymn from Nippur, of the Time of the Dynasty of Agade, 2800-2600 B.C.:

GEORGE A. BARTON.

This cylinder was found at Nippur by Dr. Haynes and, after its arrival in Philadelphia, re-

mained until recently unpacked in the basement of the University Museum. The cylinder was originally six and one half inches long and approximately four and one half inches in diameter. It was inscribed with nineteen columns of writing, each slightly less than three fourths of an inch wide. One side of the cylinder, to the width of eight columns of writing, is broken away, but seven fragments of this portion have been found in the packing-boxes. From these fragments it has been possible to recover a portion of each of the columns of writing. On account of the crumbling of the clay, parts of some of the columns on the main portion of the cylinder are illegible. The script of the inscription is that of the dynasty of Agade, 2800-2600 B.C. The language is pure Sumerian. From the frequent references to a "foundation" in the text, it is probable that this was a foundation cylinder. Similarly the frequent references to sickness make it probable that a plague had recently visited Nippur. Parts of the text remind one of the incantations of later times; in parts there are beautiful descriptions of nature.

The name of the rebuilder of the temple and the author of the inscription have been broken away. The following are samples of its text:

The lord of darkness guards man;
The lord of light guards man;
The lord of life guards man;
The lord of the sanctuaries guards man;
The grain for thy animals he increases;
God favors man.

The following extract shows that the Nippurians were not strangers to the charms of the flowing bowl:

The eye of wine presents 36,000 openings,
The bright eye is very brilliant,
Like the goddess, the great mother.
O our lady, mighty one, brilliant goddess,
Unspeakable is the splendor of thy vegetation!

The sickness is referred to in the following:

The fiery tablet of Enlil
To Nippur
Against the sickness he has brought;
With Ishtar of Erech for the protection of thy
land from death
Against the sickness he has brought it;
With Ea thy chief,
Against the sickness he has brought
The fiery tablet of Enlil.

And again:

Enlil declares:
"Gone is the sickness from the face of the
land."
As a protector he removed it—
Enlil's are they—
As a protector he removed it.

The last words that can be made out of the remaining text are:

He protects thee from death
And an evil fate.
This foundation Enzu laid,
Tappinu-grain he makes abundant,
Thy land he protects, he establishes for men.

FRIDAY EVENING, APRIL 24

Reception from 8 to 11 o'clock

at

*Hall of the Historical Society of Pennsylvania,
S. W. Corner of Locust and Thirteenth Streets*

Arthur L. Day, Ph.D., director of the geophysical laboratory of the Carnegie Institution of Washington, gave an illustrated lecture on "Some Observations of the Volcano Kilauea in Action," at 8:15 P.M.

SATURDAY, APRIL 25

Executive Session—9:30 o'clock

Stated Business.—Candidates for membership balloted for.

Morning Session—10 o'clock

William B. Scott, Sc.D., LL.D., Vice-president, in the chair.

Primary Cambrian Manganese Deposits of Newfoundland: NELSON C. DALE. (Introduced by Professor W. B. Scott.)

Geology of the Wabana Iron Ores of Newfoundland: ALBERT O. HAYES. (Introduced by Professor W. B. Scott.)

Hewettite, Metaheuwettite and Pascoite, Hydrous Calcium Vanadates: W. F. HILLEBRAND.

The Relations of Isostasy to a Zone of Weakness—the Asthenosphere: JOSEPH BARRELL. (Introduced by Professor Charles Schuchert.)

The mass of every mountain or mountain range tends to deflect the plumb-line toward it and slightly away from the true vertical, so that the measured latitude and longitude of any locality will differ slightly according as it is determined by triangulation from other regions or by independent astronomic determination of the point in which the observed vertical pierces the celestial sphere. But Hayford has shown that the deflections of the vertical are actually only one tenth of the deflections calculated as due to the terrestrial relief. This is a quantitative test of the degree of isostasy and shows that the continents stand high above the ocean floors because they are underlain with lighter matter. Such a relation of density to relief explains the almost complete neutralization of the gravitative effect of the relief and

accounts for the smallness of the observed deflections of the vertical, averaging for stations in the United States only about three seconds of arc. Dynamically it implies a state of flotation of the crust upon the inner earth analogous to the flotation of an iceberg in the ocean.

Yet the earth as a whole is known to be about as rigid as steel; the nature of earthquake vibrations transmitted through the earth shows it to be solid throughout and more incompressible and rigid at great depths than near the surface. Within the limited range of temperatures and pressures open to experiment Adams has added to the evidence and shown that rocks possess greatly increased strength under cubic compression. Furthermore, the writer has published recently some calculations which show that the loads supported by the strength of the crust are much greater than had been generally supposed. The delta built out by the Niger River, for example, is equivalent in mass to at least 2,000 feet of rock above sea-level, extending over a circular area not less than 300 miles in diameter.

How then shall the geodetic evidence pointing toward a general flotation of the crust near to equilibrium be reconciled with this other evidence of great rigidity and strength? It has long been supposed that a mobile zone may explain the apparent contradiction, but the necessity of postulating such a zone becomes greater as the accumulated evidence of weakness, on the one hand, of strength, on the other, diverges more and more. It is the consideration of the depth and physical nature of this zone which is the thesis of the present paper.

By means of a study of the area of the surface loads and their degree of departure from isostatic equilibrium this zone is located far deeper than other estimates have placed it; the level of minimum strength being thought to lie as much as 150 to 200 miles deep. The maximum strength is probably at a depth of 10 to 20 miles and falls off rapidly below. At great depths the earth is doubtless again much stronger and resists deforming stresses as would a globe of steel. In physical character this zone of weakness is thought to possess high elasticity, but, under prolonged stresses, a low elastic limit. This shell of the earth plays such an important part in geologic dynamics that it is thought to merit a special name—the sphere of weakness—the asthenosphere.

Evidence for a Pulsational Change of Climate in the Libyan Desert: WILLIAM H. HOBBS.

The Cretaceous-Tertiary Boundary in the Rocky Mountain Region: F. H. KNOWLTON. (Introduced by Professor John M. Clarke.)

As a result of certain stratigraphic and paleobotanical work in the Rocky Mountain region, Mr. Knowlton became convinced some years ago that the then accepted boundary line between Cretaceous and Tertiary would require readjustment to bring it in harmony with ascertained facts. Evidence bearing on this point has been cumulative, and as a final result he feels justified in presenting and defending the following thesis: The dinosaur-bearing beds known as the Ceratops beds, Lance Creek beds, Lance formation, Hell Creek beds, Sombra beds, Lower Fort Union, Laramie of many writers, Upper Laramie, Arapahoe, Denver, Dawson, and their equivalents, are above a major time break and are Tertiary in age. Stratigraphic, diastrophic and paleontologic evidence in support of this contention were presented.

The Geologic and Biologic Results of a Study of the Tertiary Floras of Southeastern North America: EDWARD W. BERRY. (Introduced by Professor William B. Clarke.)

The results of several years of study of the exceedingly rich Tertiary floras of southeastern North America were announced for the first time. Their botanical relationships and their bearing on the evolution of types and upon geographical distribution were summarized. The geological results include the recognition of hitherto unknown intervals during which many thousands of square miles were above sea-level. These studies have also afforded for the first time fossil floras of fixed stratigraphic position for comparison with the floras of the Rocky Mountain Province on the border between the Cretaceous and the Tertiary whose age has been the occasion of several decades of controversy. They also afford means for correlation with the type section of the Paris basin, and likewise furnish a large body of evidence bearing upon geological climates and other physical features of the past.

The Burgess Shale Fauna of the Canadian Rockies: CHARLES D. WALCOTT.

On Multiple Treatment of One and the Same Story "Motif": MAURICE BLOOMFIELD.

Some Biblical Miracles: PAUL HAUPT.

The Sumerian Pronunciation of the Name "Ninib" as the Chief Deity of Umma: ALFRED T. CLAY.

Panama Tolls and Tonnage Rules: EMORY R. JOHNSON.

SATURDAY, APRIL 25

Afternoon Session—2 o'clock

William W. Keen, M.D., LL.D., President, in the chair.

Unveiling of a medallion portrait of the late Sir Joseph Dalton Hooker, O.M., G.C.S.I., C.B., by William G. Farlow.

Symposium on Physics and Chemistry of Protoplasm—

The Germ Plasm as a Stereochemic System: EDWARD T. REICHERT. (Introduced by Dr. Keen.)

Arrangement and Distribution of Substances in the Cell: EDWIN GRANT CONKLIN.

Vital Staining of Protoplasm: HERBERT MCLEAN EVANS. (Introduced by Professor Piersol.)

Protoplasm does not exist as a substance, but only as an organism; it is never found in the mass, but only in the form of cells. Even the simplest cells are complex structures consisting of many parts. In practically all cells there is a central portion, the nucleus, which is sharply marked off from the surrounding portion or cell body. Each of these portions is further subdivided into different parts or substances; the most constant differentiations of the nucleus are chromatin and achromatin, of the cell body cytoplasm and metaplasm. Other differentiations which are frequently present are centrosomes or division centers, with surrounding archiplasm, cell membranes, cortical layer of cytoplasm, central cytoplasm and perinuclear plasm.

The relative positions of different cell constituents vary in different kinds of cells, and in the same cell at different phases of cell life or under different environmental conditions. In cells which are not dividing the nucleus usually lies near the center of the cytoplasm, though it may be eccentric toward the side on which nutriment is received and away from the free border of epithelial cells. The centrosome usually lies at the pole opposite the nucleus and toward the free border of epithelial cells. The chief cell axis is the line connecting centrosome and nucleus. Thus many cells have a definite polarity.

In some plant and animal cells the contents circulate in a more or less definite manner; this is called cyclosis. In dividing cells the movements of cell contents are most marked, the movements taking place largely around the centrosomes which serve as centers of diffusion currents. These diffusion currents start at the time when the sub-

stance of the nucleus begins to mingle with that of the cell and they not only distribute the cell contents in a definite way, thus causing differential or non-differential division, but they also probably cause the separation of the chromosomes and the division of the cell body.

When a spermatozoon enters the cortical layer of an egg, or when this cortical layer is pricked by a needle, the substance of this layer flows rapidly to the point of entrance, where it forms an entrance cone, while the sperm head with some of the cortical substance penetrates to the interior, and the egg and sperm nuclei then approach one another. Then the cell movements connected with the first cleavage begin and the egg substances become segregated and localized by means of these currents into areas which give rise to particular organs. Since the pattern of this localization is different in different groups of animals, it must be that there is an internal regulating mechanism which determines the direction and extent of the movements within the cell.

Finally the relative sizes, positions and order of appearance of different parts of a cell during division, or of an egg during the early stages of development, are indicative of certain generic relations between these parts. The centrosome and archiplasm are thus found to be causally connected with the achromatin of the nucleus; the chromatin grows at the expense of the achromatin; and the cell body influences the growth of the nucleus, while the nucleus influences the differentiations taking place in the cell body.

All of these complicated morphological and physiological phenomena are doubtless the expression of chemical and physical processes occurring in the cell; a few of these processes may now be indicated, but that which is known is as nothing compared with what remains to be learned about the physics and chemistry of the cell.

The Physical State of Protoplasm: G. L. KITE.
(Introduced by Professor McClung.)

An accurate knowledge of the physical state or conditions of living matter has been gained for the first time by the employment of new methods for the dissection of living cells under the highest power of the microscope. Most living matter has been definitely proved to be in the jelly state. In a few kinds of cells the living substance is a liquid. Micro-dissections have thrown new light on the distribution of jellies and liquid in living cells and proved for all time the physical reality of such important structures as chromosomes, nucleoli and spindles.

The Physico-chemical Organization of the Cell:
LAWRENCE J. HENDERSON. (Introduced by Dr. H. F. Keller.)

At the banquet on Saturday evening at the Bellevue-Stratford about eighty members and guests were present, the toasts being responded to as follows:

"The Memory of Franklin," by Hon. Mayer Sultzberger.

"Our Institutions of Learning," by Professor J. Dyneley Prince.

"Our Guests," by Professor Maurice Bloomfield and Sir Ernest Rutherford.

"The American Philosophical Society," by Russell Duane.

ARTHUR WILLIS GOODSPEED

PHILADELPHIA,

May 4, 1914

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 525th regular meeting was held April 4, 1914, in the assembly hall of the Cosmos Club, with Vice-president Dr. W. P. Hay in the chair, and 35 persons present.

Wm. Palmer gave the first paper on the regular program: "Notes on the Hatching of a Local Terrapin (*Kinosternon pennsylvanicum*).'" From 4 to 5 eggs are found in nests of this turtle. The contents of one were transferred to the yard of Mr. Palmer's house in Georgetown, and apparently hatched, only after a lapse of 13 months. Mr. A. A. Doolittle and the chairman discussed the paper, the latter remarking that the diamond-back terrapin presents a similar case. The eggs are laid in the spring, and although hatched in the fall, the young sometimes remain in the nests until the following spring.

The second paper by Dr. O. P. Hay, was "An Account of a Visit to Some of the Smaller Museums." On a recent trip the speaker had visited some 40 towns for the purpose of examining specimens of Pleistocene vertebrates. He gave an account of the size and character of the collections in various towns and remarked upon the conditions under which the fossils were deposited. At Mount Union Scio College, Ohio, was seen a skull of the giant beaver, which was 13 inches long, the largest known. At Norwalk, Ohio, was found a specimen of the ground sloth (*Megalonyx*), which establishes the fact that these animals existed after the retreat of the last ice sheet. At Kansas City, Kansas, is the head of a whalebone whale, said to have been found in Oklahoma. It is undoubtedly modern, and the datum erroneous. The

most general fault with the small museums is the lack of labeling, particularly as to locality.

Dr. J. O. Snyder then presented the last paper of the program, entitled, "The Fishes of the Lahontan Basin, Nevada, their Habits and their Relation to the Geology of the Region." Dr. Snyder stated that his communication was a synopsis of the results of a scientific and practical investigation for the Bureau of Fisheries, of the following lakes and their tributaries, Eagle, Hone, Tahoe, Pyramid, Winnemucca, Carson and Walker, representing at least five distinct systems.

The fish fauna includes the following genera: *Catostomus*, *Leuciscus*, *Rutilus*, *Chasmistes*, *Salmo*, *Agosia*, *Cottus* and *Coregonus*. The speaker discussed all but the last three.

The minnows of the genus *Leuciscus* change color constantly as they become sexually mature, and this change in appearance has resulted in a multiplicity of names for a single species. These little fish follow the suckers and feed eagerly on their eggs.

Chasmistes, a fish practically unknown to science, since the original description was found to spawn in immense numbers in the Truckee River. They were so numerous as to crowd part of their number out on the sandbars where they died. Large quantities are caught and dried by the Piute Indians.

Trout are abundant in the Lahontan basin. They belong to three main groups, the brook trouts, the red-spotted, and the cut-throats, each with numerous races. The silver trouts of Pyramid and Winnemucca lakes are distinguished from those of Tahoe by color, but not otherwise. They ascend the streams to spawn, in two migrations, the individuals of the two schools differing considerably in appearance.

The royal silver trout, a new species recently found in Lake Tahoe, is remarkable in remaining unknown to science for so long. It has long been known to local fishermen, and their descriptions of its peculiarities were confirmed when Dr. Snyder received specimens. The species is regarded as a superior food fish, and for this reason has not reached the markets, being kept for home consumption.

The La Hontan Basin is surrounded by San Joaquin, Sacramento, Klamath, Columbia, Bonneville and Colorado systems, but is isolated from them. Geological evidence is to the effect that the basin has always been without outlet. So far as the fish fauna is concerned, *Chasmistes* points to a possible relationship with the Klamath and Bonneville systems, in both of which it is found.

This communication was discussed by Messrs. A. A. Doolittle, M. W. Lyon, Wm. Palmer and the speaker.

The 526th regular meeting was held April 18, 1914, in the lecture hall of the Cosmos Club, with Vice-president Dr. J. N. Rose in the chair and 40 persons present. Under the heading of brief notices, President Paul Bartsch commented on the absence of red-headed woodpeckers in the vicinity of Washington. Apparently none had wintered and it was thought migrants were overdue. Dr. M. W. Lyon gave similar testimony. Mr. Alex. Wetmore said the species was seen along the Patuxent River, Md., March 15, and that in his experience, when the red-head is not present in winter it does not return till late.

Titus Ulke then gave the first paper on the regular program, entitled, "Notes on Bermuda Birds." The speaker noted the large number of birds that have been recorded from the Bermudas, a large proportion of which are casual visitors. He then gave notes on the distribution, habits and local names of the following 18 species: Bermuda catbird, bluebird, northern water-thrush, Bermuda white-eyed vireo, European house-sparrow, Bermuda cardinal, belted kingfisher, pigeon hawk, Bermuda ground-dove, golden plover, jacksnipe, great blue heron, bittern, coot, black duck, blue-winged teal and European goldfinch. The paper was discussed by Messrs. T. W. Vaughn, Wm. Palmer, W. L. McAtee and the author.

T. Wayland Vaughn then delivered his communication on "Reactions of Corals to Food and to Non-nutrient Particles, and the Nature of the Food of Corals." He first gave a sketch of the structure of the coral polyp, in so far as it is related to prehension and assimilation of food. The entire ectoderm of the animal is armed with nematocysts for disabling living prey. It is further covered with mucus and is provided with cilia which waft food toward the mouth and rejected objects away. Experiments in feeding coral polyps were made with the following substances: bits of crab meat, cut-up minnow and beef juice. When solid food was placed on the oval disc, the tentacles expand, bend over, and pass food to mouth; the edges of the oval disc contract over the mouth until swallowing is completed. The impulse to expand the tentacles stimulated by a food particle is communicated from polyp to polyp until the whole colony is expanded.

Corals can be satiated with food, and when this condition is reached all objects are wafted away

from mouth. Corals free themselves from foreign objects, as sand. These are sometimes swallowed, but eventually all are rejected. Corals living where wave action is great have less power to cleanse themselves than species living on sand or mud-flats.

Corals sometimes swallow as large objects as small jellyfish and crabs. In experiments they took pieces of fish, crustacea and even pieces of other polyps. They ate also every kind of marine plankton, except Pycnogonida, which were rejected. Every copepod dropped on the oval disc of a coral or even on the column wall was killed and wafted to mouth. No vegetable matter of any kind was taken. Pure cultures of diatoms were invariably rejected; if dipped in beef juice diatoms were swallowed, but later ejected. Bits of seaweed were similarly treated. The conclusion is, therefore, that coral polyps are strictly carnivorous. The communication was discussed by Mr. A. A. Doolittle and the speaker.

Mr. A. A. Doolittle then gave the last paper of the program: "The Plankton Resources of Some Massachusetts Ponds." He spoke of the bearing plankton studies have on the broad problem of the conservation of natural resources. A study of the plankton is necessary to the utmost utilization of the fish resources, since practically all fishes, at some stage of their existence, feed on plankton, especially the entomostraca.

In the eight Massachusetts lakes studied, samples were taken from bottom to surface and in all parts of the lakes. Twenty-six species of Entomostraca were collected, one new. Copepods were much more numerous in individuals than the Cladocera, and composed from 50 to 75 per cent. of the total plankton. The number of plankton under a square yard of surface varied from seven thousand to eighty-two thousand. The largest numbers were found in the shallower lakes. The number per cubic yard of water varied from 500 to 17,500, the largest number by this estimate also in a shallow lake. In fact the number of plankton varies inversely as the depth, the deeper parts of quiet lakes having few or none.

Knowing the amount of plankton in a lake, if stomachs of fish are examined to determine the amount they consume, we can estimate the number of fishes the water may support. Mr. Doolittle's paper was discussed by Drs. C. D. Marsh and M. W. Lyon.

The 527th meeting was held May 2, 1914, in the lecture room of the Cosmos Club, with Vice-presi-

dent Dr. W. P. Hay in the chair, and 46 persons present. Frederick M. Gaige, University of Michigan and Frederick C. Lincoln, Colorado Museum of Natural History, were elected to membership. It was announced that the 527th would be the last meeting of the season.

In response to the call for brief notes, W. L. McAtee compared the abundance of birds in the neighborhood of the District of Columbia, as stated in Coues's and Prentiss's lists of 1862 and 1883, with that of the present. Discussion followed by Wm. Palmer and W. W. Cooke.

Calling Dr. M. W. Lyon to the chair, Dr. W. P. Hay gave the first paper of the regular program: "A Journal of the Wilkes Exploring Expedition." The journal in question is a manuscript by Mr. Sinclair, the navigating officer of Captain Wilkes' flagship. Dr. Hay sketched the history of the Wilkes' expedition, gave the personnel of the scientific staff, and an account of the itinerary of the voyage. He also noted the character and manner of distribution of the de luxe report on the expedition, which was in 20 volumes and of which only 100 sets were distributed.

The journal of Mr. Sinclair began at Norfolk, Va., August 9, 1838. Dr. Hay read various excerpts, relating to the following subjects: the death and color changes of the dolphin, a waterspout, phosphorescence, behavior of whales; notes on the towns of the west coast of South America, including Valparaiso and Callao; description of the cruise to the Antarctic, including notes on the aurora, icebergs, penguins, seals, storms and the discovery of land; the last excerpt read was a description of San Francisco. The paper was discussed by Drs. M. W. Lyon and Theodore Gill.

The second contribution to the program was an account of the home and country of Linnæus by S. M. Gronberger, illustrated by lantern slides. Mr. Gronberger sketched the home, school and professional career of Linnæus, and gave an account of his travels. He showed views of Linnæus's home and country, as it now is, and spoke of the distinguished visitors entertained by Linnæus and the mode of life of these companies. Numerous views of places of historical interest also were shown.

The evening's program was completed by the exhibition of an interesting series of lantern slides of Washington's wild flowers by L. D. Halleck. Wm. Palmer spoke briefly on certain of our wild flowers, remarked on their cultivation, and gave running comments on the slides.

W. L. MCATEE,
Recording Secretary pro tem.

CUSSONS APPARATUS

The "Atwood's Machine"

The Patented Ribbon Atwood's Machine shown in the illustration is a new form, and furnishes an excellent means of illustrating the laws of falling bodies. A graphic record of the fall is made on the paper strip, connecting the weights. The motion of a single lever allows the weight to drop, and sets the pendulum in vibration. With the use of this machine, results are obtained which cannot be approached in accuracy by any other apparatus.

Other Cussons products which have met with wide-spread approval are the Mathematical Models, Capstan Block Apparatus, Machine and Steam Engine Models, and Apparatus for Experimental Mechanics, catalogs of which, with attractive "Duty Free" price, will be sent on request.

IMPORTANT SCIENTIFIC BOOKS

Animal Communities in Temperate America. A Study in Animal Ecology. By VICTOR ERNEST SHELFORD, Instructor in Zoology in the University of Chicago.

380 pages, 8vo, cloth: \$3.00, postage extra (weight 44 oz.)

This volume by Dr. Shelford presents the principles of field ecology, illustrated by the more widely distributed animal habitats of the eastern half of temperate North America, and the aquatic habitats of a much larger territory. Six chapters deal with general principles. In several chapters animal communities of lakes, streams, swamps, forests, prairies, and various soils and topographic situations are considered from the point of view of modern dynamic ecology. A very valuable feature of the book is the three hundred figures of widely distributed animals chosen to represent the chief types of animal communities and their characteristic modes of life.

Bulletin of the American Geographical Society. This book is unique in that it is a pioneer of its sort and the first serious attempt to treat of the physiology of organisms and of animal communities in such shape as to serve as an adequate text and reference work for students.

Artificial Parthenogenesis and Fertilization. By JACQUES LOEB, Member of the Rockefeller Institute for Medical Research.

318 pages, 12mo, cloth: \$2.50, postage extra (weight 36 oz.)

This new work presents the first complete treatment of the subject of artificial parthenogenesis in English. It gives an account of the various methods by which unfertilized eggs can be caused to develop by physico-chemical means, and the conclusions which can be drawn from them concerning the mechanism by which the spermatozoon induces development. Since the problem of fertilization is intimately connected with so many different problems of physiology and pathology, the bearing of the facts recorded and discussed in the book goes beyond the special problem indicated by the title.

British Medical Journal. The author has gained a world-wide reputation for his achievements in artificial fertilization, and this work shows how, according to his observations, the action of well-known chemical and physical agencies may be substituted for that of the living spermatozoon.

THE FINANCIAL STATUS OF COLLEGE TEACHERS¹

IN 1908 the Foundation reported in its second bulletin the results of an enquiry concerning the financial status of the teaching staff of higher institutions in America and Germany. An examination of salary schedules for the year 1912-13 makes it possible to treat certain of the topics of that bulletin more fully and to measure the change in salaries during the past five years.

THE VARIABILITY OF SALARIES IN THE SAME INSTITUTION

A small institution performing a fairly unified educational service, such as giving instruction in the traditional academic subjects, or training engineers, or teaching law, may do its work conveniently with a staff of men graded rather sharply as, say, professors, assistant professors and instructors, with a fixed salary attached to each grade or title. The teaching staff may even be on almost absolute financial equality, four fifths of its members being "professors" and doing the work of teaching with here and there an assistant of lower title and salary.

Such simple fiscal arrangements were common a generation ago; they still persist in some of the older and smaller colleges; but they are now becoming obsolete, and no one can understand the financial sta-

¹ Based upon a study by Professor Edward L. Thorndike, of Teachers College, Columbia University, of reports made by the institutions to the Foundation. From the eighth Annual Report of the President of the Carnegie Foundation for the Advancement of Teaching.

tistics of our higher institutions by thinking of the teaching staff as sharply graded by a few academic titles, and of each title as significant of a given salary. Where there are professional schools, the salary attached to the title of professor may, in the same institution, range from \$500 to a maximum of \$5,000, there being actually twenty-five different sums received as annual salaries by the full professors in a single American university. In this institution thirteen different sums, ranging from \$750 to \$4,000, were received by persons who held the title of associate professor; fourteen different sums, ranging from \$1,800 to \$3,600, by assistant professors; and eighteen different sums, ranging from \$200 to \$2,000, by instructors. There were also clinical professors, clinical instructors, and several other academic grades causing further variability, and within each of these grades there was a still further variability of its own.

Even where there are no professional schools, the variation of salary is very great. For example, in two institutions without professional schools nineteen different sums, ranging from \$2,000 to \$5,000, were received by professors; thirteen different sums, ranging from \$600 to \$1,700, by instructors; and sixteen different sums, ranging from \$1,000 to \$3,000, by officers of intermediate grades. This variation is for the salaries of men—were women included, it would be greater. So far as could be ascertained, all of the salaries considered, except perhaps some of those for instructors, were for the full year's work of full-time teaching. There were both lower and higher salaries than those mentioned, but these were for exceptional conditions, as of part-time teaching or administrative work.

Both institutions illustrate the overlapping of academic grades with respect to

salary. Over one fourth of the teachers of intermediate grade receive salaries as high as, or higher than, the lowest full professor's salary; nearly one fourth of the instructors receive salaries reaching or passing the lowest point for salaries of teachers of intermediate grade. Such overlapping is in no sense exceptional; in the larger institutions the fact that certain individuals of lower rank receive more salary than other individuals of higher rank is so frequent as to be almost the rule.

THE SALARIES OF THE TEACHING STAFF OF COLLEGES AND UNIVERSITIES IN 1912-13

Such variability of salary for the same academic grade, either by the separation into distinct salary steps or by a gradual ranging, together with the overlapping of academic grades in salary, make the financial statistics of higher institutions difficult to present and interpret without misleading. The difficulty is increased by the differences in practise between institutions and between the same institution in different years, with respect to the significance of a given academic rank. For example, associate professors may be far above assistant professors in dignity and salary in one institution and in another be substantially on a level with them. The average salary of assistant professors may appear to have been lowered between 1907-08 and 1912-13, when in reality such service was better rewarded than before by the addition of a higher intermediate grade or title for those performing this service, and the relegation of the title of assistant professor to those performing a different service. Other complexities are added by differences in policy as to the distribution of salaries within the same grade, differences in the services performed by different individuals of the same grade, and the like.

The only sound and adequate basis for

a statement of the financial status of the teacher in a higher institution is a list of names, giving in each case salary, age, absence and pension rights, services performed, services permitted outside the institution, amount of training, and amount of experience in the institution and elsewhere. No college or university publishes such a list, and it is doubtful whether any governing board keeps such a systematic list, though it is precisely these facts that a competent head of department or college president has in mind and combines with his knowledge of the teacher's scholarship, efficiency and devotion in recommending financial provisions. It is a regrettable fact that at present we know far more about such topics as the relation of age to salary, or of length of experience to salary, in the case of elementary and high school teachers than in the case of college teachers. Indeed, the published facts for the last are practically limited to the survey made in the bulletin of the foundation to which reference has been made.

The first step obviously is to provide knowledge of the salaries that are actually paid, and this the foundation is enabled to do, through the courtesy of institutions in submitting their pay-rolls for study. As the common statements of average salaries give such imperfect and misleading notions, the detailed distribution of the relative frequencies of each salary has been studied.²

² Some thirty group tables were made for the following colleges and universities: *Group 1*, Carleton College, Franklin College and Ripon College; *Group 2*, Bates College, Clarkson School of Technology, Drury College, Grinnell College, Lawrence College and Mount Holyoke College; *Group 3*, Drake University and Newcomb College (of Tulane University); *Group 4*, Beloit College, Centre College of Kentucky, Dickinson College, Hobart College, Marietta College and Wabash College; *Group 5*, Hamilton College, Oberlin College, University of Pittsburgh, Tufts College and

The facts as reported are not offered as infallible in every respect. The foundation was unwilling to impose on the institutions concerned the burden of answering detailed questions; consequently a salary may occasionally be recorded as smaller than it really was (because the individual was on leave of absence for part of the year, or was in receipt of an added payment under another department), or as larger than it really was (because a payment recorded on the pay-roll in a second department was actually included in the first payment recorded). Some mistakes of copying in and from the pay-rolls and in further tabulations are probably inevitable. The facts reported give, however, a thoroughly trustworthy general picture of what they attempt to present.

The facts compiled are for salaries in 1907-08 as well as in 1912-13, permitting measurements of the rise of salaries as well as of the present status. They are arranged

Washington and Jefferson College; *Group 6*, Middlebury College, University of Rochester, University of Vermont and Wellesley College; *Group 7*, Bowdoin College, Clark College, Indiana University, Purdue University, Swarthmore College, Trinity College (Connecticut) and Union College; *Group 8*, Dartmouth College, University of Missouri and Worcester Polytechnic Institute; *Group 9*, Lehigh University, University of Minnesota, Tulane University, Washington University (Missouri) and Western Reserve University; *Group 10*, University of Cincinnati and Vassar College; *Group 11*, Amherst College, University of Virginia and Williams College; *Group 12*, Cornell University, University of Michigan and University of Wisconsin; *Group 13*, Case School of Applied Science, Rensselaer Polytechnic Institute and Stevens Institute of Technology; *Group 14*, University of California, Massachusetts Institute of Technology and University of Toronto; *Group 15*, Johns Hopkins University, Leland Stanford Junior University, Princeton University and Yale University; *Group 16*, Columbia University and Harvard University. None of these group tables is here published, but the foundation will be glad to make them available to scholars.

in four divisions—salaries for instructors or tutors or whatever grade represents approximately the first rank of teachers with a full program, salaries for full professors, salaries for standard intermediate grades, and salaries for all of these grades combined. The salaries of assistants, or whatever grade represents approximately the work of men who are primarily students, are not included. The salaries of irregular grades, such as lecturer, which may carry an instructor's work or a part-time professor's work, or signify casual visits, or a dignified assistantship, are likewise excluded. Presidents are also excluded, but deans and directors of schools or departments are included. Teachers in medical schools, dental schools and schools of pharmacy are also excluded, being more fitly made the subject of separate study. Payments for work in summer schools are excluded. The salary of a teacher in service for only one semester is recorded as it would be for a full year's service. The aim is to show the recompense given for what is a teacher's full service in any institution in question. Although there are doubtless occasional failures to make the necessary distinctions precisely, the tables show the typical with adequate precision. In the salary scales, which form parts of the table, \$400 means from \$350 to \$449, \$500 means from \$450 to \$549, \$600 means from \$550 to \$649, and so on.

Upon examination of Table I. it will be seen that the institutions do not differ very greatly in the salaries given to instructors. We may, without serious error, group all these salaries for all institutions. The low-salaried institutions pay in the main from \$750 to \$1,200, the others from \$750 to \$1,500. It must be remembered that some of the instructors in the larger institutions included in these tables, though carrying a full program of class teaching,

are really of the apprentice type, engaged in study for a higher degree. The instructor in these colleges is somewhat better paid than the male teachers in American high schools. The median salary for the latter is \$900; the average salary, little if any over \$1,000; and the proportion of salaries at \$500 to \$900 much greater. It is perhaps worthy of mention that the salaries of the mechanics employed in university shops and laboratories are distinctly below the average instructor's salary in the same institution. Fuller analysis of the financial status of the instructor must be delayed until enough individual life-histories of college teachers are available to permit the correlation of salary with age, experience in teaching, and amount of education received in preparation for teaching.

In the salaries attached to intermediate grades, associate professors, and assistant professors, institutions differ more widely. The gradation is rather steady, so that any grouping of the institutions has to be somewhat arbitrary, and its results are necessarily less instructive. There are groups of institutions with average salaries for the intermediate grades of \$1,200 to \$1,400; with average salaries of \$1,488, \$1,537 and \$1,571; with average salaries of \$1,747 to \$2,076; and lastly the Harvard-Columbia group with average salaries still higher.

These summaries appear in Table II. There are no clear "species" of teachers in this grade from the fiscal point of view. By reason of age, ability and differences in the significance of the titles concerned, the salaries spread from \$1,000 to \$4,000 with no close grouping around specially frequent salaries, save perhaps around \$1,500 for the colleges of moderate salary-schedules. If the grade of associate professor had been kept separate throughout, there would have been a somewhat, but not much, closer

TABLE I
THE SALARIES OF INSTRUCTORS IN 1912-13

1,582 individuals
Median salary \$3,000

salary, there would be a fairly pronounced influence of this sort.

We may say roughly that the teachers in intermediate grades in the smaller institutions are financially in a class with the instructors in institutions like Columbia, Harvard, Yale, Hopkins, Stanford, California and Princeton. How often they are, like these latter, young men proving their worth, and how often they are mature men whose achievements have not been such as to put them ahead financially, is a question to be settled only by proper measurements of the correlation of age with salary. The teachers in intermediate grades of institutions like Oberlin College get from \$1,200 to \$1,800, and represent gifted young men, somewhat older men waiting for fairly assured promotion, and still older men who have nearly or quite reached their salary limit as college teachers. The 890 teachers in intermediate grades in institutions like Dartmouth College or the University of Minnesota represent the group of assistant professors whose status has been studied by Professor Guido Marx,

plus a financially superior group of junior professors and associate professors in large institutions.

In the case of the full professors, we have in Table III. the story of the salaries of mature men and women, accepted as teachers of the highest rank, in sixty-one institutions. This fairly represents the status of the full professor in the hundred and fifty better higher institutions of America.

There is a certain significance in the combined facts for the salaries of all these full-time teachers of accepted standing in the higher schools of America, which are shown in Table IV., although in this table all ages and all of the institutions are mixed. The significance lies in the possibility of easy comparison with similar facts for other professions or branches of civil service, and of easy contrast with salaries in industrial and commercial organizations. One such comparison with the salaries of men teachers in public high schools of the United States is made in the table itself.

TABLE IV
THE DISTRIBUTION OF THE SALARIES 1912-13
Of the 4,262 Instructors, Assistant Professors, Associate Professors and Professors in the 61 Institutions Combined

THE RELATION OF SALARY TO AGE

An adequate treatment of the relation of salary to age requires the fiscal history of individual teachers. To infer the changes in salary due to age from the differences found between the salaries of groups classified by age is unsafe, since those who abandoned college training for other occupations at any age are very likely to differ as to salary from those who remain, and since we can not assume that the ability of those entering college teaching has remained constant during the forty years past. The foundation hopes to give the topic such adequate treatment in the future. The present section reports only measures of the variation of salary at the same age for certain groups—a limited and not exactly representative selection from college teachers of 251 men, all teachers of mathematics or the natural sciences in certain universities, who had been active enough in science by the year 1910 to be included in the second edition of Professor Cattell's "American Men of Science." The choice of these was dictated by practical exigencies and the results must not be taken strictly at their face value, although the use made of the facts has been kept free from fallacies due to the nature of the selection of these individuals. The selection is such as to exclude men of all ages of slight scientific achievement and to exclude somewhat more strictly the youngest. Also, as stated, it is a selection of men from, on the whole, a superior group of institutions.

In general, we have a fairly steady rise in salaries from the group of age 34 with a median salary of \$1,800, through age 36 at \$2,000, age 38 at \$2,200, age 40 at \$2,500, age 42 at \$2,200, age 45 at \$2,850, to \$3,200 at age 49, and \$3,300 at age 53. For the reasons stated, this result should be used with caution. What is certain is

that the effect of age within these limits is real, large and more persistent to later ages than probably would have been assumed *a priori*.

There is an interesting difference in salary and in the relation of age to salary between the men who were rated in Professor Cattell's list of the 1,000 most esteemed as scientific workers and those who were less distinguished. In salary the more distinguished group have an advantage of about \$800 at ages 36 and 38, about \$1,000 at ages 40 and 42, about \$1,500 at ages 44 and 46, and a still greater advantage at later ages. The median salary for the distinguished group rises from about \$3,000 at ages 36, 38, 40 and 42, to \$3,500 at ages 44 to 46, \$4,000 at ages 48, 50, 52 and 54, and \$5,000 at higher ages; while the median salary for the others remains at approximately \$2,000 through ages 36 to 46, and is only \$2,500 and \$2,650 in the case of ages 48 to 54 and 56 and over. These figures are from too few cases to be used as precise measures of the differences in question, but are adequate to prove that ability as estimated by one's fellow scientists receives very substantial recognition in salary, and that, as in other professions and in industry and commerce, the less gifted men reach their maximum salary much earlier than the more gifted.

The variation in salaries for the same age is, as students who have made the matter a subject of careful observation and thought would expect, very wide. Men not over two years apart in age differ in respect to salary to such an extent that the highest salary is about four times the lowest. The intervening salaries are spread fully over the scale. Men receiving \$2,000 may be from under 30 to over 60 years old, and men can be found with that salary at every intervening age. The effect of more

complete and more exactly representative data would be to increase the range of variation. This variation, it may be added, is a sign of healthy adaptation to the wide differences in energy, scholarship and devotion which must be expected even within such a picked group of men as college teachers.

THE APPRENTICESHIP SYSTEM IN AMERICAN HIGHER INSTITUTIONS

The higher institutions of America maintain an elaborate system of apprenticeship by their provision, fiscal and otherwise, for assistants, readers, teaching fellows and the like, who do educational work under more or less close supervision, generally as part-time workers who are studying for a degree, or who have just completed such study and are maintaining financial independence while waiting for engagement as full-time teachers.

The extent of this apprentice work in the larger institutions may be estimated from the fact that in Columbia, Harvard, Chicago, Michigan, Yale and Cornell there are reported 761 individuals with the title of assistant, more than the number of full-time professors in these same institutions. Some few of these are full-time teachers or scientific workers of experience,⁹ but there are, to much more than counterbalance these, teaching fellows and young men with the title of instructor who are really apprentices.

The system is by no means confined to the large universities. Taking at random ten institutions of moderate size (Vassar, Indiana, Purdue, Oberlin, Cincinnati, Armour Institute, Virginia, Washington, Western Reserve and Brown), we find reported 237 assistants to 321 full professors.

⁹ In departments of agriculture especially, subordinate scientific workers with salaries of from \$800 to \$1,500 are often given the title of "assistant."

Moreover, there probably are other student assistants unreported because receiving only free tuition.

Even in the small institutions, much of the educational work is done by, and much practical training in college teaching is given to, such apprentices. Again taking ten colleges at random (Lafayette, Bowdoin, Colorado College, Dickinson, Adelphi, University of South Carolina, Goucher, Trinity (Connecticut), Beloit and Washington and Jefferson), we find reported 72 assistants to 157 full professors. Fifty-two of these were reported from a single institution, but, on the other hand, the student-assistants who were given tuition or tuition plus a hundred dollars or so were probably very often left unreported by other institutions in this group.

The fiscal status of these apprentices will not be described here, since any tables of salaries or changes in salaries for them are likely to be misleading unless worked out and presented in connection with fairly exact descriptions of the services which they perform and the training which they receive. These services range from the actual conduct of class-room and laboratory instruction to the mere correction of minor written exercises, or even to work as errand boys, keeping class-rolls, answering the telephone and fetching apparatus. In time required they vary so much that an assistant's pay probably would show a range of from fifty cents per hour to five times as much. The training ranges from such sympathetic guidance as a son might receive in a model father's office to the mere orders and criticisms that an ordinary office boy gets.

It is probable that four out of five of the men and women now entering college and university teaching hold such positions as paid assistants for a year or more. Consequently the organization and remuneration

of the work attached to assistantships offers important problems to the scientific student of administration. At its best an assistantship means self-support while advancing in knowledge and professional training for the assistant, equally good instruction for the classes in question, relief for the professor who can devote himself to work that he prefers, though it is in the popular sense much harder to do, and economy for the fiscal authorities who are enabled to pay certain services no more than efficiency requires.

THE CHANGE IN THE SALARIES OF TEACHERS IN HIGHER INSTITUTIONS

The salaries of instructors have shown a clear increase during the past five years. There has been an average gain of \$80. This gain has been caused by a decrease in the proportions of salaries of \$1,000 and under and an increase in the proportions of salaries of \$1,050 and over. The increase has been greatest in the groups of institutions paying on the average under \$1,000 in 1907-08. The gain for these averages \$118, and their median salary has moved up from \$900 to \$1,000. The gain has been least in the institution groups which had the highest salaries in 1907-08, except Harvard and Columbia, being \$63 for the combined group including California, Massachusetts Institute of Technology, Toronto, Johns Hopkins, Stanford, Princeton, Yale, Harvard and Columbia, and much less if Harvard and Columbia are excluded.

Table V. gives the percentage of instructors receiving less than \$650, the percentage receiving from \$650 to \$849, the percentage receiving from \$850 to \$1,049, and so on, both for 1907-08 and for 1912-13. It will be seen that all the low salaries have decreased in relative frequency, while all the high salaries have increased.

TABLE V
CHANGE IN INSTRUCTORS' SALARIES
All Institutions Combined; Coarse Grouping

Salary	Percentile Frequencies		Differences
	1907-08	1912-13	
Under \$650	2.6	1.4	- 1.2
\$650- 849	13.0	9.9	- 3.1
850-1,049	42.6	31.7	-10.9
1,050-1,249	23.6	26.8	+ 3.2
1,250-1,449	10.8	18.6	+ 7.8
1,450-1,649	6.2	8.7	+ 2.5
1,650-1,849	.7	1.4	+ .7
1,850-2,049	.5	1.2	+ .7
2,050-2,249		.1	+ .1
2,250-2,449		.1	+ .1
2,450-2,649	.1	.1	0

The change in the salaries paid to teachers of intermediate grades is complex and difficult to express. In the institutions paying in 1907-08 in most cases from \$1,000 to \$1,500, clustered around an average of about \$1,200, there has been an average gain of about \$200. This gain concerns positions filled by 110 individuals in 1907-08, and by 161 in 1912-13. In Harvard and Columbia, at the other salary extreme, there has been an average gain of \$226. Here 116 and 160 positions were concerned in 1907-08 and 1912-13, respectively. The remaining institutions, with 660 positions for 1907-08 and 979 for 1912-13, show an average gain of about \$120, the gain being closely the same whether an average of \$1,500, \$1,600, \$1,700, \$1,800 or \$2,000 was paid in 1907-08. The intermediate grades have then made most improvement in the institutions which in 1907-08 paid the very low or the very high salaries.

The general change is shown in Table VI. which gives the percentages (in 1907-08 and in 1912-13) of teachers receiving each salary amount. The grouping shows with special clearness the decrease in relative frequency of salaries below \$1,500 and the increased relative frequency of salaries above \$1,850. The change has been

an advance all along the line, not the mere bringing of very low salaries up to a higher standard, nor the addition of certain high-priced positions.

TABLE VI

THE CHANGE IN SALARIES OF TEACHERS OF INTER-MEDIATE GRADES FROM 1907-08 TO 1912-13

All Institutions Combined; Coarser Grouping

Salary	Percentile Frequencies		Differences
	1907-08	1912-13	
Under \$950	.4	.1	— .3
\$950-1,249	11.6	4.8	— 6.8
1,250-1,549	23.7	19.8	— 3.9
1,550-1,849	25.9	25.7	— .2
1,850-2,149	20.1	22.0	+1.9
2,150-2,449	6.1	9.6	+3.5
2,450-2,749	8.2	9.5	+1.3
2,750-3,049	2.6	5.8	+3.2
3,050-3,349	.4	.3	— .1
3,350-3,649	.2	1.1	— .9
3,650-3,949	.1	.1	0
3,950-4,249	.4	.6	+ .2
Number of individuals...	946	1,300	

The salaries of full professors in these institutions have been increased on the average by about \$225, the increase being about the same for institution groups paying salaries, in 1907-08, of \$1,200, \$1,400, \$1,600, \$1,800, \$2,200, \$2,700 or \$3,000. The institution groups paying average salaries (in 1907-08) of \$3,500 and \$3,750 show smaller gains, about \$125; Columbia and Harvard show larger, about \$350. The low-salaried institutions have thus increased their professors' salaries by a percentage far greater than that of the high-salaried institutions. The general change is shown in Table VII. which gives the relative frequencies of each salary amount in steps of \$500 in 1907-08 and 1912-13 for all of the institutions combined. The decrease in the lower salaries is clearly shown, the professorial staff having been moved up by about \$200 all along the salary scale.

TABLE VII

THE CHANGE IN SALARIES OF FULL PROFESSORS FROM 1907-08 TO 1912-13

All Institutions Combined; Coarse Grouping

Salary	Percentile Frequencies		Differences
	1907-08	1912-13	
\$750-1,249	2.9	.8	— 2.1
1,250-1,749	12.3	9.4	— 2.9
1,750-2,249	16.2	14.5	— 1.7
2,250-2,749	15.3	17.1	+1.8
2,750-3,249	19.9	17.6	— 2.3
3,250-3,749	9.9	12.6	+2.7
3,750-4,249	12.6	12.3	— .3
4,250-4,749	2.8	4.3	+1.5
4,750-5,249	4.4	6.1	+1.7
5,250-5,749	2.1	2.6	+ .5
5,750-6,249	.5	1.6	+1.1
Over 6,250	1.0	1.2	+ .2

From the results of this new examination of the financial status of college teachers, it will be seen that the situation, as compared with that of five years ago, is encouraging. In spite of a variability of salaries in the same institutions and of a financial overlapping of academic grades, there is coming to be a kind of general agreement upon a salary for a college instructor that is rather better than that of the man who teaches in a high school. Junior professors in the smaller colleges receive salaries almost equal to those of instructors in the large universities. Of 1,500 representative full professors one fourth receive \$2,250 or less, one fourth \$3,750 or more, and one tenth \$5,000 or more, the median salary of all being \$3,000. All salaries have increased during the last five years—those of instructors have risen by about \$80, those of junior professors show a gain of from \$120 to \$226, those of full professors show an increase of from \$125 in the smaller institutions to \$350 in the largest. Teachers who by general agreement are considered distinguished receive from \$800 to \$2,400 more than their colleagues of the same age.

SOIL EROSION AND ITS REMEDY BY TERRACING AND TREE PLANTING¹

PEOPLES have the habit of visiting their heaviest penalty—death—upon those offenders who imperil the life of the community. For example, horse-stealing among cowboys, destroying bridges among the Caucasus mountaineers. By the same reasoning the time is approaching when the permitting of gullying and soil erosion will rise in our minds from waste to offense and finally to crime.

Soil erosion is an irreparable waste, perhaps the only irreparable waste, when in an age of science one considers the great possibility of substituting one substance or commodity for another. Once the soil is gone, it is gone, and can not be returned. In locations of shallow soils underlaid with rock, a very small amount of erosion throws land out of agricultural use for a geologic epoch.

Owing to our vast resources and cheap land and the scientific nature of erosion control, little has thus far been done to check erosion either prohibitively or constructively. Another reason why we have done or appreciated so little in this field is that the problem is relatively new to the Teutonic peoples.

I. FACTORS TENDING TO AGGRAVATE AND INCREASE SOIL EROSION IN AMERICAN AGRICULTURE

1. *Relation of Agricultural to Nature's Erosion Control.*—Nature controls erosion with plant roots, so that in most of the United States the problem scarcely existed before white men's agriculture began here. The beginning of agriculture here was not merely the introduction of an old-established method. American agriculture is unlike that of Europe

¹ Section I., of the A. H. A. S., has a committee on soil erosion. This committee appointed J. Russell Smith, Ph.D., professor of industry in the Wharton School of Finance and Commerce, University of Pennsylvania, a subcommittee to gather information as to the relation of tree crops to the erosion problem. This paper presented at the 1913 meeting of the section is the result of journeys of investigation in the Mediterranean countries and islands and in central and southern United States.

and far more deadly as a promoter of erosion. European agriculture has but little bare ground, most of the crops covering the entire surface of the ground and holding it with a root mass, as does wheat, barley, clover. America has added to the European agriculture the three great bare-ground crops of corn, cotton and tobacco. The tillage of these crops prepares the ground for erosion. The soil is kept bare, loose and soft. Frequent cultivations gash it ready for the starting of the digging rills of running water when a storm comes.

2. *The New and Erosive Type of Rainfall.*—Another factor, new to the Caucasian race, is a heavy summer rain which exists in all the territories growing these three crops, and comes in the peculiarly destructive form of a thunder shower, with its tremendous powers of eroding loose bare soil.

3. *The Increasing Area of Erosion-inducing Crops.*—The increasing demand for these bare-ground crops tends more and more to make us cultivate and destroy hilly lands which, while in good pasture or forests, erode but little.

II. FACTORS IN EROSION CONTROL

1. Deep plowing has been extensively recommended by our agricultural authorities, but casual observance of hill lands almost anywhere shows it to be but a partial remedy, and corn and cotton fields under the best recommended deep plowing can often be shown to be eroding at rates that are completely ruinous if kept up for any long period.

2. Contour plowing tends to diminish erosion, but this device is hostile to the American system of farming that is characterized by the utilization of machinery sweeping in straight lines over large areas.

3. Terracing has been quite widely used in the south, but usually in a relatively inefficient way because in effect it chops a field up into a multitude of small fields of irregular shape. Between these little patches are untilled banks that grow weeds instead of crops. We have, however, the recent discovery of the Mangum terrace worked out by a farmer at Wake

Forest, N. C., and now adopted by the Federal Department of Agriculture. It is a great improvement over any terracing to be found in either Europe or America. It consists of wide gentle ridges plowed up along the face of the slope so that the water flows slowly and harmlessly along it, while its wide gentle slope permits the planting of crops and the utilization of agricultural machinery directly across it at the same time that it controls the runaway waters. There is almost no washing of earth where the system is maintained, and the ground is fully utilized in the American way.

A proper appreciation of the economic and far-reaching importance of soil saving should bring us in a short time to a point where, by compulsion or premium, all tilled lands liable to washing would be handled by this method or some other equally efficient one.

4. Plowless utilization of land offers great possibilities for the checking of erosion and the vast increase of our crop area.

(a) *Forestry and Pasture*.—Thus far tree planting in the form of forestry has been almost the sole panacea, other than pasture, for steep lands. The fruitlessness and slowness of a forest, which yields its one crop in from twenty to one hundred and fifty years, is a profound objection to it as a resource for the owner of the average small farm. The yield of hill pastures is too small to be a satisfactory dependence. Therefore, we have plowed, gullied and destroyed.

The inefficiency of pasture is indicated by its almost entire elimination in the arable areas of western Europe where it has given away to tilled crops. Its inefficiency in comparison to tree crops is shown by the fact that the pounds of food, the income and the nutrition produced by an acre of good sheep pasture in England are less than that produced by a good walnut tree in France.

(b) *Crop Trees*.—The tree is nature's real engine of production. This scientific fact seems to have been overlooked, despite the great value that trees have been to us. By a spasmodic and chance development, the tree has given us a number of valuable tree crops. The land that is in harvest-yielding trees is

usually the heaviest yielding and most valuable land. Witness the orchards everywhere. The king of all crops, as measured by the greatest amount of food produced and the value of the land, is a tree crop—the date.

Past development of tree crops has come peculiarly by chance. Now that we know how to breed plants, we need the systematic examination of all the trees of the country with regard to their present or potential crop possibilities. This is a task requiring much work and having tremendous promise of increased national wealth. This conclusion is borne out by the facts now known concerning American trees, and by the occasional development of tree agriculture both in this country and in Europe.

In this country while we have an extensive fruit industry, it has touched but a small corner of the possible tree-crop field, and the crops have been limited chiefly to those fruits that may be classed as succulents rather than nutrients, and they have been limited also to human food rather than to forage. Forage is the great demand upon the American farm. The animals eat several times as much as we do.

1. *Tree Forage*.—Forage tree crops in Europe, Africa and Hawaii, are suggestive of great developments in America. The carob bean, worth about one cent per pound at the farm, is a much prized nitrogenous and also carbohydrate stock food widely grown from Gibraltar to Palestine, and exported to England and to some extent to the United States. In Hawaii we have its counterpart, the mesquite bean, a bran and corneal substitute, rapidly becoming an important industry. The yields reported by the Hawaiian Experiment Station are almost staggering in their significance. Mesquite forests on rough untilled and untillable land are producing from 4 to 10 tons of beans per acre and the bean meal sells at \$25 a ton. We have in the United States, waiting to be developed, similar leguminous, cropping trees growing from the Pacific to the Atlantic in the form of the mesquite in the west and the honey locust in the east, both great bean-yielding trees.

The European utilization of the acorn as swine food amounts to millions of dollars annually, and while we have some hundreds of thousands of hogs using the bought privilege of eating the acorns of our national forests, no one seems to have seriously considered the possibility of investigating the American oak as a corn substitute, yet there is good reason to believe it may be more effective than corn in many localities. American trees yielding several hundred pounds of acorns are common.

The utilization of the fig in Majorca and Portugal gives us added reason to contemplate the great possible service of mulberries and persimmons as automatic pig feeders, the crop being harvested by the animals themselves. The extensive use of the chestnut as a corn forage substitute in the mountainous parts of Italy, Corsica and France shows us what we might do in Appalachia with native or imported chestnuts, and also with hickories and other native nut trees.

2. *Major Foods from Tree Crops.*—The great dietary wants of man are proteid for tissue, carbohydrate and fat for energy. None of these wants has been met to any important extent by a tree crop in the United States. The proteid demand is substantially met in Europe by the use of the walnut, almond and filbert. Unquestionably the native and Persian walnuts of the United States, along with that remarkable tree, the pecan, and the numerous native hickories and hazelnuts, offer us great possibilities of new and extended industries and new staple food supplies.

The carbohydrate tree crops of the Old World are even more important than the proteids. The date (more nutritious than bread) is the main stay of vast areas, and the fig (even more nutritious than the date) is also a great food. The chestnut is, to large areas of Spain, France, the Mediterranean islands, and Italy, the same thing that corn is to the Appalachian mountaineers—a great starch food. The acorn, with an analysis much like that of wheat, excepting a shortage of protein, has for ages been a food for many Mediterranean peoples, and holds out at any time the possibility of being made into a very accepta-

ble farinaceous food for the American people if they should choose to develop it, in an age of science and factory-prepared foods. Fat is furnished in Europe by the olive to so great an extent that the olive covers a larger proportion of Spain than wheat does in the United States. We have not yet developed an oil industry, although the resources are at hand.

3. *Areas and Adjustment.*—The tree is plainly our best means of utilizing steep and rough land, and if we can develop means of utilizing the cropping tree without the plow, we can easily double the crop area of the United States. At the present time tree crops cover only about one fiftieth of our agricultural area, when they apparently possess the possibility of covering half of it with great profit and with a permanence of production now unknown.

The example of a thousand per cent. increase in value of a Corsican hillside when well established in chestnut orchards that have never been plowed and which have produced for centuries, is exceedingly suggestive.

The problem is not merely a problem in forestry, for it is an established fact, that the fruiting trees must have sunshine on all sides. Numerous modifications of the forestry situation, however, suggest themselves. Tall trees like the pecan might be surrounded by coppices of leguminous trees like the locust, which might attain salable size, and by their nitrogenous roots greatly enrich the soil, as is the case where certain leguminous trees are grown with coffee. Crop trees like the pecan and walnut, persimmon or mulberry might be surrounded by thickets of bush size legumes, which absolutely maintain the soil against erosion, which enrich it, and which might be annually cut in the place of being annually plowed, or they might be pastured once a year with goats, and thus kept under control, made to render their service to the crop tree, and still give some value as forage.

4. *Moisture and Fertility Control.*—American agriculture is unquestionably suffering from too great a conviction that cultivation

is essential to the preservation of moisture and the supplying of fertility.

There is little doubt that the earth mulch, a preparation for erosion, does make the fertility more available, and does check evaporation. We need much more knowledge than we now have as to whether or not the same results may not be obtained by the application of mineral or other chemical fertilizers, which will increase natural vegetation, which will therefore increase humus, and the natural water-holding power of the soil. Rather convincing evidence as to the efficacy of this latter method is to be had in the sod mulch orchards under the care of the Ohio Agricultural Experiment Station, and also in the variation of crop yields in rich and poor lands in a dry season in the Berber villages of Northern Algeria. At the present moment the idea of the maintenance of fertility and a good crop yield without tillage is so unorthodox that almost no experiment stations in the United States will look at the subject with respect, yet in it lies great possibility of the extension of tree-crop agriculture to large areas of land where cultivation is difficult and is almost synonymous with erosion unless careful terracing shall be worked out.

The actual holding of water upon the ground until it sinks in is an aspect of the matter well worthy of extensive investigation. The mangu terrace, which is so efficient in taking water away from a hillside without erosion, can doubtless be enlarged and made absolutely horizontal so that it will keep the water where it falls, after the practise of Colonel Freeman Thorpe, of Hubert, Minnesota. This is a practise worthy of much experimentation, and one which fits peculiarly into the tree-crop idea. It is doubtless true that in many localities the water standing behind the horizontal mangu terrace would injure wheat, clover and other small crops. On the other hand, there seems to be little reason to anticipate that it would injure trees that stood upon the terrace and had their roots beneath the reservoir of water, which might stand and freeze for considerable periods with no injury to the tree, which would get the water when it soaked

into the ground. This has been proved successful for 20 years in a Pennsylvania apple orchard.

This practise has been worked out for many decades in the olive orchards of Central Tunis around Sousse, and it unquestionably can be utilized with tree crops in many parts of the United States. Its limitations must be defined by experimentation, which may also find aids in the growth of deep-rooting annual plants to increase porosity and absorbing power of the soil.

There also appears to be no reason why this mangu terrace might not be modified into a series of basins that would hold near each tree the water that fell near it, and thus practically apply the methods of the California water economizing irrigators. Such preparation of the soil would be effective for many years and would therefore be less expensive than annual cultivation.

An effect of this holding of water where it fell would be the absolute stoppage of a loss of fertility that results from the washing away of incrustations of soluble salts deposited through the evaporation of earth moisture at the surface. The effectiveness of this process in bringing earth salts to the surface is well known. It has given us our alkali soils, but we owe it to Colonel Freeman Thorpe to call our attention to its surprising effectiveness as an agency in fertility loss where water is allowed to run off of the surface. This factor alone may be found worthy of all the effort necessary to hold water where it falls.

III. CONCLUSION

If the economic botanists and plant breeders can give us a series of new cropping trees which will furnish new foods for both man and beast, we will have an economic factor which will combine a number of forces, because it helps to meet a number of needs. It will greatly stimulate food production, also wood production. Through the development of the plowless agriculture and terrace water holding, we will have conservation of the soil and of fertility. We will also have in this combination the greatest of all forces yet

brought to bear upon the problem of flood control, and also a great aid to navigation and irrigation, because of the better conservation of water in the soil for springs and streams.

It is a problem with which the individual farmer of an intellectual turn of mind can experiment in a small way, but above all it is one which needs, even demands, the attention of the federal government and many of the agricultural experiment stations.

J. RUSSELL SMITH

UNIVERSITY OF PENNSYLVANIA

*THE MASSACHUSETTS INSTITUTE OF
TECHNOLOGY AND THE STATE*

IN an address at the annual banquet of Technology alumni in January, Governor Walsh suggested a closer cooperation between the institute and the state. The result has been, in its successive steps, the appointment of a special committee to consider the matter by Jasper Whiting, president of the alumni association, a conference with the governor in March, an investigation of all the sources of information and a report to the alumni council on May 25. The latter while it has naturally been based on the institute and its resources proves to be so broad in its applications that there is place in the plan for all the institutions of the state that can give advice. "When they are so harnessed to the state's interest," the report reads, "they will constitute a great state university geographically diversified, possessing the momentum of valuable traditions, the strength of long years of experience and moral influence through their great alumni bodies—all this making of them units, which if assimilated by a wise state policy will form a coordinated system of educational facilities, which in its broadest sense is a university."

First there is recommended legislation which shall increase and regularize the services of members of the faculty of the institute (and other institutions, to be specified in the act) on state boards and commissions, either as members or in an advisory capacity. Such legislation should be applicable to all state commissions which conduct work requiring

scientific or technical skill or advice. Suggestions for direct payment for such services direct to the institution are made, since it is best fitted to apportion such payments between individual service and the use of the laboratories of the school.

The second recommendation is that the use of the laboratories and shops of the institute be placed at the service of the state under appropriate conditions which will safeguard the educational purpose of the institute and the administrative needs of the state. No direct charge should be made for the use of these laboratories, but the state should bear the expenses of labor and material plus a fixed sum to be added to cover wear and depreciation. Provision should be made for an equitable adjustment of this charge.

For its third suggestion the committee advises the establishment of a bureau of technical information, which shall without charge furnish to the state and the public, advice which may be obtained without substantial expense, either in furnishing ordinary scientific information or indicating the lines of inquiry to be followed.

The committee recommends the appointment by the governor of a permanent committee on cooperation to carry into effect these recommendations, to study further the needs of the state as to closer cooperation between it and the institute and additional means of making such cooperation effective. Such a committee would also look forward to a system of cooperation between the state and the various other educational institutions.

The committee finds that from its inception the Massachusetts Institute of Technology was intended to serve the scientific needs of the state and its people. Its charter looks to aiding the advancement, development and practical application of science in connection with the arts, agriculture, manufacture and commerce. In this department of its activities the committee finds momental achievements to the credit of Tech in many different divisions of work. In fact the whole history of the institute shows that the institute has given to the state and that the state has drawn freely from

the institute. The state has availed itself of the faculty of technology and of the shops, laboratories and experiment stations and it has furnished problems for the student body. But all of this, the committee believes, has been in an incidental and casual way. There has been cooperation undefined, unguided and fragmentary. It has lacked the stimulus of continuity or organization, the spur of recognized state service. "The time has come," writes the committee, "to formulate the union, to make it official, to the end that the institute may be strengthened, in power and prestige, and that the state may derive in full the benefit at hand."

PRESERVATION OF THE NATIONAL MONUMENTS OF CHINA

PRESIDENT HENRY FAIRFIELD OSBORN of the American Museum of Natural History has addressed under date of May 14, 1914, to Secretary of State Bryan and to President Yuan Shih-k'ai of China, the following letters relative to the preservation of the art and historical monuments of China.

HONORABLE WILLIAM J. BRYAN,
Secretary of State,
Washington, D. C.

Sir: The Chinese race furnishes perhaps the greatest of all records of human society, and its future is closely associated with the destiny of society in this hemisphere. Our country contains an ever-increasing number of men and women devoted to the hope of China's triumph in modern civilization and government, in which case she will extend her matchless social and human experiment continuous from the remotest times unbroken. In this connection interested persons and institutions in the United States are seeking to establish in China a school of archeology as a means to encourage protection of the antiquities of China and provide for study there of China's ancient history.

On account of the ruthless destruction and plunder of antiquities in China since 1900, involving American citizens, the following individuals and organizations represented, having memorialized President Yuan Shih-k'ai as shown herewith, have the honor to request your aid in the official transmission of their memorial herewith enclosed, directly to Peking.

Furthermore, we have the honor to request:

First, That the Department of State, through its officials in China, use such means as it may determine to discourage all American citizens from vandalizing in China and from trafficking in broken and stolen sculptures and other archeological and art works of historical value belonging to the people of China, and to render aid with counsel wherever possible to shield Americans from being involved with plunderers of Chinese antiquities, and in all ways possible assist in preserving the good name of the United States, its citizens, agents and institutions, free from connection with the destruction of Chinese monuments and antiquities and the traffic in stolen and otherwise immorally or criminally obtained Chinese objects of antiquity.

Second, That the Department of State, officially, semi-officially or unofficially, as possible, through its officials in China and elsewhere, discourage the plunder and destruction of Chinese antiquities in times of peace or war in China, whenever opportunities permit, and support and encourage the Chinese officials and people in taking effective means to conserve their antiquities for China's benefit and the benefit of other nations.

Respectfully submitted,
(Signed) HENRY FAIRFIELD OSBORN,
President

PRESIDENT YUAN SHIH-K'AI.

Sir: We have learned with profound concern, that through various evils of modern origin, monuments and antiquities in China invaluable to present and future generations of Chinese and to the world, have been irreparably lost and destroyed; that the high material value put by Western civilization upon antiquities and products of art showing the progress of mankind, has lately resulted in the commercialization, plunder and destruction of antiquities in China beyond the power of ordinary influences to control; furthermore, that such plunder and destruction not only are despoiling China of some of the garments of her ancient civilization, but actually tend to break down Chinese society by depriving the Chinese people of their heritage, besides crippling research and education, and retarding progress;

Therefore, having a friendly interest in the good of China and the republic, and having in mind the interests of enlightenment of human welfare generally, as well as the responsibilities devolving upon the nations and upon all well-wishers and friends of China, we have the honor herein to memorialize your Excellency and respectfully and earnestly to urge as follows:

That in view of all the circumstances and conditions; in accordance with ample traditional practice and precedent established by China's ancient rulers; and in cooperation and harmony with the policy of the most advanced governments, the national government of China make new legal recognition of China's monuments and antiquities, and of all forms of national art of antiquarian and historical value as national property, and, in the manner adopted by other nations, newly take national possession of the same and bring them under national protection for preservation in China for the lasting benefit of the Chinese people and of mankind generally.

Respectfully submitted,
(Signed) HENRY FAIRFIELD OSBORN,
President

THE BRITISH ASSOCIATION IN AUSTRALIA¹

At the end of June and in the first week of July 400 members of the British Association for the Advancement of Science will leave England to meet for the annual sessions of the Association in the state capitals of Australia. The visit is made at the invitation of the Australian Commonwealth Government, whose guests the members of the association will be, and by whose generosity so protracted a journey is made possible.

Such a meeting is memorable in many ways. It adds completeness to that system of exchange of scientific thought and scientific men between the United Kingdom and the Dominions over-seas which has been steadily growing since the beginning of the century; and it will serve to link still more closely the newer universities with the older throughout the whole of the Empire. The previous visits of the British Association to Canada and to South Africa gave fresh impetus to scientific work, and were followed by tangible results in the creation of new scientific institutions and laboratories. There is assurance beforehand that this precedent will be repeated in Australia, for one of the objects of the visit is to afford opportunities for joint discussion on cooperation in research between the southern continent and the countries of the Northern

Hemisphere in astronomical, meteorological and anthropological problems.

There are advantages of a reciprocal kind to those who would not otherwise sacrifice four months of the scientist's year in a visit to Australia. Problems await attack in solar physics and in the distribution of the stars; problems in the evolution of segregated species of animals and plants; of physiological adaptation; of atmospheric electricity and earth magnetism; of the antiquity of races and of the development of social conditions—in short, problems affecting every department of science, which can only be carried to completion with the aid of data obtained in the Southern Hemisphere and the southernmost continent.

The commonwealth government, the state universities and the Australian people are making every provision that the fullest opportunity shall be given to the meeting to investigate both the work that is being done and that which has to be done in the fields of zoology, botany, physiology and engineering. It should be added as not the least remarkable of the circumstances of this meeting that this is the first time that any government has set aside so large a subsidy for the purposes of the encouragement of science.

The members of the association proceed in two parties. The advance party of 70, in which the president-elect, Professor William Bateson, F.R.S., travels, and which takes with it a number of zoologists, botanists and geologists, will go by way of the Cape to Perth, in Western Australia. This party stays a week, making excursions for field work in the sand plains, in the Darling Range, the Irwin River district, the coast or the Kalgoorlie goldfield during the larger part of it; and, at most, three evening lectures will be delivered, one of them by Professor Herdman on "Life of the Sea," and another by Professor A. S. Eddington on "The Stars and their Movements." This visit is an unofficial part of the meeting; but since among those who take part in it are Professor F. W. Dyson (the astronomer royal), Professor H. E. Armstrong, Professor Poulton, Professor Dendy and Professor W. J. Pope (presidents respectively of the

¹ From the London *Times*.

zoological and chemical sections), Professor A. D. Waller, Sir John Biles, Dr. A. C. Haddon and Mr. A. D. Hall (president of the agricultural section) it is very strongly representative of the main body.

The rest of the party, the main body, will pick up the advance party at Perth about August 7 and will sail with them for Adelaide. If it had not been for the death of Sir W. H. White, who was to have been president at Birmingham last year, Sir Oliver Lodge would have been the president for the Australian meeting; and Australia has been eager to welcome him in his presidential capacity. Consequently he has been asked to deliver an address, and has consented. At Adelaide he will speak at an evening meeting on "The Ether of Space," and this valedictory discourse will embody his conclusions as to the objective reality of this concept, and his criticisms of the new mechanics by which an attempt is being made to replace it. Dr. W. J. Sollas, of Oxford, will deliver the other evening discourse on "Ancient Races and Their Modern Representatives"—of whom he believes the extinct Tasmanians to have been the most primitive—and Sir Charles Lucas and Mr. A. D. Hall will address their sections of geography and of agriculture.

From Adelaide, after a stay of four days, the association will go on to Melbourne, which with Sydney will be the auditorium of the larger part of the addresses, papers and discussions. Following the precedent of South Africa, the presidential address of Professor Bateson will be divided into two parts. The address in Melbourne will discuss the problem of evolution in the light of Mendelian discoveries. Professor Bateson will especially attempt a consideration of the nature of variation, showing the extreme difficulty of any longer maintaining the received doctrines on these subjects. At Sydney he will proceed further to show the application of the results of Mendelian analysis to man, pleading for simpler views of life and death and for a fuller recognition of biological knowledge in regard to conduct and the ordering of social structures.

The president's address will be delivered on the evening of August 14, and on that morning and on two other days the sections of mathematics, chemistry, zoology, economics and physiology will meet. When the association is adjourned and meets again in Sydney (August 20) the second part of the presidential address will be delivered and the remaining sections of geology, engineering, anthropology, botany and education will assemble. In another week the members move on again to Brisbane, where the sections of physiology and agriculture reassemble and where an address will be delivered by Professor W. E. Brown on "Cosmical Physics." These addresses and evening lectures are a special characteristic of the meeting, and among those who deliver them will be Sir E. A. Schafer on "The Origin of Life," Sir E. Rutherford, Professor Elliot Smith, Professor N. E. Armstrong, Professor E. B. Poulton, Professor G. W. Howe, Professor H. H. Turner, Professor B. Moore and Dr. Rosenhain.

After leaving Sydney some of the members of the association will visit New Zealand, and others will go to Tasmania. After the concluding meeting at Brisbane some will return directly home, but a number, splitting into larger or smaller parties, will continue the program of excursions which are so liberally provided for in the program of the month's meeting. One party, for example, will travel across North Queensland, others will visit New Guinea, where the commonwealth government has placed a yacht at the disposal of a specific anthropological investigation; and there are many other excursions for those who have time to make them before returning home by way of New Guinea and Java.

SCIENTIFIC NOTES AND NEWS

WITH the close of the present term at the Massachusetts Institute of Technology, Professor Robert H. Richards will retire from the active work of teaching which he has followed for forty-six years. He is made professor emeritus and receives the benefits of the Carnegie Foundation. Professor Richards has

been identified with the institute since its beginning, he was a student in the first class and a graduate in the first group to receive the B.S., following which he became assistant—1868-1871—and then in 1871 took the chair of mineralogy, in the department that afterwards developed into that of mining engineering and metallurgy.

PROFESSOR JOHN PERRY has recently retired from the staff of the Imperial College of Science and Technology, and a fund is being raised for the purpose of giving expression to the appreciation of his services to the teaching of mathematics and to engineering education.

THE astronomer royal, Mr. Frank Watson Dyson, has been elected Halley lecturer at the University of Oxford for next year.

LORD LAMINGTON has accepted the office of president of the Research Defence Society, in the room of the late Sir David Gill.

THE honorary degree of doctor of engineering has been conferred upon Commerzienrat Carl Paul Goerz, the head of the Goerz Optical Works, by the Technical High School in Charlottenburg.

DR. SMITH ELY JELLIFFE, of New York City, has been elected a corresponding member of the Paris Neurological Society.

PROFESSOR GEORGE C. WHIPPLE, of Harvard University, has been chosen as one of three American engineers to act with three Canadian engineers to advise with the International Joint Commission on matters pertaining to the pollution of the Great Lakes. Professor Whipple has also been chosen a member of a commission consisting of five sanitary engineers to advise the commissioner of health of New York State on matters pertaining to the location of tuberculosis hospitals on catchment areas used for public water supplies.

DR. C. E. MENDENHALL, professor of physics at the University of Wisconsin; Dr. Knight Dunlap, associate professor of psychology at the Johns Hopkins University and Dr. W. E. Burge, assistant professor and acting head of the department of physiology at the University of Illinois, have accepted invitations to

carry on research work during the coming summer in Nela Research Laboratory (formerly known as Physical Laboratory, National Electric Lamp Association). Dr. Willibald Weniger, of the Oregon Agricultural College, has also been secured for special research work during the summer and Mr. A. F. Wagner, of Purdue University, has been appointed to a temporary assistantship in the laboratory for a part of the vacation period.

AN exhibition of photographs by Mr. A. Radclyffe Dugmore, the African traveler and author of works on photographing big game in their native haunts, is being held at the house of the Royal Photographic Society, London.

PROFESSOR MARSHALL H. SAVILLE, of Columbia University, has sailed for Colombia, to make archeological explorations there and in Ecuador.

DR. J. N. ROSE, research associate in the Carnegie Institution of Washington, left New York on June 10 for the west coast of South America, where he goes under the auspices of the Carnegie Institution of Washington and the New York Botanical Garden, for the purpose of making a special study of the Cacti of the deserts of Peru, Chile, Argentina and Bolivia. He expects to send large collections of living plants to the New York Botanical Garden. He will be absent from Washington between four and six months.

PROFESSOR ALBERT JOHANNSEN, of the University of Chicago, has sailed for Europe to spend the summer in the mineralogical laboratories of Germany and Austria.

SIR ERNEST SHACKLETON with nine members of his expedition have visited Norway to test provisions and motor-sledges for his forthcoming Antarctic expedition.

AT Cornell University officers of Sigma Xi have been elected for the ensuing year as follows: *President*, Professor A. W. Browne, department of chemistry; *Vice-president*, Professor J. G. Needham, department of biology; *Counsellor*, Professor D. S. Kimball, Sibley College; *Recording Secretary*, Professor F. K. Richtmyer, department of physics; *Corre-*

sponding Secretary, Professor James McMahon, department of mathematics; *Treasurer*, Professor W. A. Riley, department of biology; *Program Committee*, Professor H. N. Ogden, civil engineering; Professor H. S. Jacoby, civil engineering; Professor A. W. Gilbert, department of plant breeding, and Professor A. W. Browne, *ex-officio*.

PROFESSOR W. M. DAVIS gave a lecture in the Town Hall at Suva, Fiji, on April 30, on "The Origin of the Coral Reefs of Fiji," in which he presented the chief results of his seven weeks' visit to those islands as a part of his Shaler Memorial study of coral reefs in the South Pacific. On May first he left for New Zealand.

ON May 25 Professor M. A. Rosanoff, of Clark University, presented before the research staff of the Mellon Institute, University of Pittsburgh, a theory of the mechanism of sugar inversion by acids.

DR. AMOS LAWRENCE MASON, senior physician of the Boston City Hospital and formerly associate professor of clinical medicine at the Harvard Medical School, has died at the age of seventy-two years.

THE death is announced of Miss Ida Freund, late lecturer in chemistry at Newnham College, Cambridge.

MR. WILLIAM WEST, lecturer at the Bradford Technical College, known for his contributions to botany, died on May 14, aged sixty-eight years.

Le Figaro for May 9 contains an announcement of the death of the noted French mathematician Jules Molke, who is especially well known to American mathematicians as the principal editor of the French edition of the large mathematical encyclopedia, which is now being published jointly by Gauthier-Villars of Paris and B. G. Teubner of Leipzig.

THE U. S. Civil Service Commission announces an examination for assistant biochemist in the U. S. Public Health Service, for duty in the field, at \$2,000 a year, and for assistant mining engineer, in the Bureau of Mines, for service in the field, in relation to

coal mining or metal mining, at salaries ranging from \$1,800 to \$2,400.

ON the afternoon of May 23, a conference was held at the Brooklyn Botanic Garden between the garden staff and the high school teachers of biology of Greater New York, as represented by the New York Association of Biology Teachers. The purpose of the conference was to offer an opportunity for the members of the association to become better acquainted with the aims, equipment and work of the garden, and to enable the latter to secure from the teachers practical suggestions as to how the garden may render the largest service to the teaching of botany in New York City and vicinity. The program was as follows:

What the garden can offer the schools.

The director of the garden.

The curator of public instruction.

The instructor.

High school classes at the garden.

The teachers of classes that have used the garden.

Suggestions from teachers.

Open discussion led by the president of the New York Association of Biology Teachers.

Following the conference there was an inspection of the first section of the laboratory building and the first two sections of the conservatories. The second section of the conservatories devoted to tropical economic plants was opened to visitors for the first time on this occasion and will hereafter be open to the public daily.

THE Harpswell Laboratory will be open for its fifteenth season from June 21 to the middle of September. It is intended to offer to investigators an opportunity to study a more northern fauna and flora than any other station in the United States. Though the laboratory is small, it has a good equipment, sufficient for any ordinary investigations. Its location, at South Harpswell, Me., on the shore of Casco Bay, assures abundant material for various lines of biological investigation, as well as a most comfortable summer climate and fine natural scenery. During the past some seventy higher institutions of learning have

been represented by workers there and a considerable amount of material has been published, based wholly or in part of investigations carried on there. This year it will be under the control of Drs. Neal and Kingsley, who have carried it on for several years, and all inquiries concerning rooms and other accommodations should be directed to Dr. H. V. Neal, Tufts College, Mass., until June 17; after that date to him at South Harpswell, Me. The laboratory, at most, can accommodate but fifteen workers at a time, and already considerable part of its space is engaged for at least a part of the summer.

It is announced that the biological laboratory of the United States Bureau of Fisheries at Fairport, Iowa, will be opened for investigators on June 15, and is expected to remain in active operation until about September 1. Those desiring to have the use of tables and other facilities for investigation may communicate with the commissioner of fisheries, Washington, D. C., or with the director of the Fairport station, Fairport, Iowa. The station is well equipped with laboratory and collecting apparatus, as well as with ponds and tanks, and supplies of river water and filtered water.

WILHELM ENGELMANN, of Leipzig and Berlin, announces the publication of the *Internationale Zeitschrift für physikalisch-chemische Biologie*. The editor is Dr. J. Traube, of Charlottenburg, with the assistance of Professor H. J. Hamburger, of Gröningen, Dr. V. Henri, of Paris, and Dr. J. Loeb, of the Rockefeller Institute for Medical Research, New York. The periodical will appear at irregular intervals, six parts forming a volume. It is hoped that about three volumes will be issued in the course of the year.

DR. VON LE COQ, the distinguished explorer, has promised, as we learn from the London *Times*, to lecture on his recent tour in Chinese Turkestan before the Royal Asiatic Society in the autumn. Writing from Berlin a few days ago he states that the results of his last journey have been very satisfactory, both in quality and quantity. His collections fill 152 cases. He worked mainly at Kucha and at Tumshug,

near Maralbashi. At Maralbashi he found a number of true Gandhara sculptures, some being exact counterparts of sculptures in slate in existing collections. But the finds, instead of being carved from Himalayan slate, were moulded in clay and plaster, some of the moulds being found alongside. Many of the "sculptures" were still covered with paint and gold leaf. He also discovered manuscripts, the first, it is believed, ever found at Tumshug. Some of these were in Sanskrit, and others, perfectly preserved, in an Iranian language. Other finds were a small but fine cornice, decorated in pure Sassanian style, and a number of heads of Sassanian knights; some good bronzes and statuettes in wood.

THE national forest reservation commission has approved the purchase of the Pisgah Forest from the estate of the late George W. Vanderbilt, at an average price of five dollars an acre. The tract consists of 86,700 acres and the total cost is therefore \$433,500. The price paid is less than the average for other tracts already acquired, although the Pisgah Forest has been developed by its former owner into one of the best forest properties in the country. This is the second time that the commission has had the purchase of this tract under consideration. Once before, during Mr. Vanderbilt's lifetime, the question of its purchase was taken up, but the commission did not deem it advisable to purchase it at that time. The tract includes portions of Transylvania, Henderson, Buncombe and Haywood counties, in North Carolina. It covers the entire eastern slope and portions of the northern and western slopes of the Pisgah range, one of the most prominent of the southern Appalachians. Its forests influence for the most part tributaries of the French Broad River which unites with the Holstein River at Knoxville, Tennessee, to form the Tennessee River. In accordance with Mrs. Vanderbilt's desire, the national forest reservation commission will retain the name of "Pisgah Forest"; in fact, the general area, in which this forest is located and in which other purchases may be made, is already designated as the "Pisgah Area." It is proposed

also to make it a game refuge for the preservation of the fauna of the eastern mountains. It is particularly well suited to this purpose since it is already well stocked with game and fish, including deer, turkey and pheasant; and in the streams rainbow trout and brook trout, with which they have been systematically stocked from year to year. With this purchase, and with others just approved, the total area approved for purchase under the Weeks law in the eastern mountains is 1,077,000 acres.

FACTS regarding our forest resources, their value and their waste, are condensed in an eight-page illustrated circular of the American forestry association just issued. The lumber industry is said to employ 735,000 people, to whom are paid annually \$387,000,000 in wages, the worth of products being \$1,250,000,000. The forests of the country cover 550,000,000 acres. An average of 70 human lives are sacrificed annually in forest fires, says the circular, and a loss occurs of \$25,000,000. Damage from insects and tree diseases, which follow fire, costs each year \$50,000,000. The cost of destruction resulting from floods is not estimated, but is given as "countless millions." But the circular expresses hope more than pessimism. As well as the colored pictures showing the forest fire, the effects of the fire, and the damage caused by floods, it shows also forests planted and grown under intensive management, and the national forest ranger scouting for fires on the mountain lookout station. The effective patrol here referred to has reduced "forest fire losses to as low as one tenth of one cent an acre." It is pointed out that by planting forests an annual income could be derived in the country of \$65,000,000; and by preservative treatment upon timber each year \$100,000,000 could be saved.

THERE has recently been established in Nela Research Laboratory (formerly known as Physical Laboratory, National Electric Lamp Association) a section of applied science in addition to the section of pure science which was established over five years ago. The section of applied science will be separate and

distinct from the section of pure science and will not restrict or in any way affect the established work in pure science. A research fellowship in ophthalmology in Nela Research Laboratory has been established for the year 1914-15. The fellowship carries with it an honorarium of \$700 and is open to men sufficiently advanced in specialized medical training to carry on an independent investigation of some problem having to do with the effects of light and attendant radiation on the eye.

WE learn from *Nature* that the movement inaugurated a few months ago to develop as completely as possible the educational side of the cinematograph made definite headway on Wednesday, May 20, when the Educational Kinematograph Association was formed at a meeting in London. Among those who have joined the council of this body are Sir H. A. Miers, Rt. Hon. Sir Horace Plunkett, Dr. C. W. Kimmins, Professor R. A. Gregory, Professor J. W. Gregory, Mr. C. Bathurst, M.P., Dr. Lyttelton, Mr. A. P. Graves, Professor Darroch, Sir Edward Anwyl, Sir Harry R. Reichel, Sir Bertram Windle, Sir Albert Rollit and General Sir R. Baden Powell. At the meeting a report was presented by the secretary, Mr. Morley Dainow, on behalf of the provisional committee, suggesting that the work of the association should be to encourage the best types of cinematograph production and develop a completely educational plan for their use. The report was adopted, subject to revision by a subcommittee. The following officers were elected vice-presidents: Sir Wm. Chance, Dr. Kimmins, Colonel Sir J. R. D. Smith, Sir Albert Rollit. An executive committee representative of educational and social welfare associations was also appointed, and Mr. Morley was elected secretary.

UNIVERSITY AND EDUCATIONAL NEWS

MR. ANDREW CARNEGIE has added, presumably from the income of the Carnegie corporation, \$2,000,000 to the endowment of the Carnegie Institute of Pittsburgh, to be equally divided between the institute and the school

of technology. Mr. Carnegie's gifts to these institutions now amount to \$24,000,000.

By the will of former Judge John Forrest Dillon, Iowa State University receives \$10,000 and Iowa College and Cornell College, \$1,000 each.

AN additional gift of \$25,000 has been received by Oberlin College for carrying out the general building plans and the improvement of grounds.

The alumni of the University of Illinois are planning to erect a \$150,000 building as a memorial to John Milton Gregory, first president of the university. It is to house an art collection gathered by Dr. Gregory and a new collection of figures and panels which the alumni association intends to buy.

THE Arnold Biological Laboratory, ground for which has been broken at Brown University, is expected to be finished a year from this summer. The building itself will cost \$80,000, while \$30,000 more will be spent upon the equipment.

THE Drapers' Company has made a grant of £200 a year for three years for anthropology at the University of Cambridge.

LAST year Sir William James Thomas, of Ynyshir, undertook to build and present to the University College of South Wales and Monmouthshire on a site contiguous to the old buildings in Newport Road a complete physiological department, so constructed as to form a part of a scheme for a complete medical school on the same site. Now, as we learn from *Nature*, a donor, who wishes at present to remain anonymous, has offered to build the whole of the buildings necessary not only for a medical school, but also a school of preventive medicine, at an estimated cost of £60,000. One of the conditions attached to the latter gift, however, is that the funds supplied by the treasury should be sufficient for the upkeep of the complete school.

CENTRAL Turkey College at Aintab has received from the Turkish government official recognition as *école supérieure*. It is the first of the American colleges in Turkey to secure

such authorization for any part of its regular curriculum.

MR. ALBERT L. BARROWS has been appointed instructor in zoology in the University of California.

DR. THOMAS H. MACBRIDE, professor of botany, has been appointed president of the Iowa State University by the State Board of Education.

DISCUSSION AND CORRESPONDENCE

THE ORGANIZATION OF A UNIVERSITY DEPARTMENT

TO THE EDITOR OF SCIENCE: I have read with interest the letter of Professor F. L. Washburn on "Heads of Departments," in SCIENCE of May 1; and it has occurred to me that your readers might be interested in an account of the present organization of one of the largest departments in one of the largest universities in America.

At Columbia University a department of English was first established in 1899 by assigning to it the professor of English literature, the professor of dramatic literature and the professor of rhetoric and English composition; and these three thereupon organized by inviting the professor of English in Teachers College to join them and by electing the professor of English literature as chairman and the professor of rhetoric as secretary. On the death of the professor of English literature, the late Thomas R. Price, the position of chairman was abolished, the senior professor of the department being expected to preside at its meetings and all the administrative duties being confided to the secretary, who was relieved of a part of his teaching that he might be enabled to carry this extra burden.

With the expansion of Columbia University and of its several colleges and schools, Columbia College, Barnard, Teachers and the School of Journalism, the department of English has grown in numbers; and several years ago the department of comparative literature was merged with it, so that it now consists of more than twenty professors, assistant professors and associate professors. And during the past fifteen years it has administered its

own affairs in town-meeting, so to speak, as an absolute democracy, in which every member has an equal voice. It has made all nominations; it has recommended all promotions; and it has requested all increase of salary; and in every case its nominations and recommendations have been favorably received by the president and by the trustees, who have granted all our requests—excepting only those not at the moment financially advisable.

Almost every member of the department serves on one or more of the special committees, to whom we confide the oversight of our several activities. Whenever we have felt the need of developing instruction in any part of our field, we have never had to draft a man for service, for all have been ready to volunteer for duty. As a result of this harmony every part of our work—graduate and undergraduate, in college and in school, and in the extension courses—has been coordinated in response to our individual and united understanding of the demands of the occasion. And so complete is this harmony, that since the department was established, no action of any kind has been taken and no recommendation has been made, other than by a unanimous vote.

BRANDER MATTHEWS

COLUMBIA UNIVERSITY,
IN THE CITY OF NEW YORK,
May 14, 1914

THE NEW FUR SEAL INVESTIGATION

THE present Commissioner of Fisheries and Secretary of Commerce, having grown distrustful of past investigators, have arranged for a new fur-seal commission for the season of 1914. To those who have followed the fur-seal situation in the past few years this is a disappointment, delaying as it does for one season more the emancipation of the herd. Without wishing to prejudice the work of the new commission, but in simple justice to those whose work is thus put on trial, it seems fair to point out certain phases of the situation which confronts the new investigators.

By the law of 1912 commercial killing of fur seals is prohibited for five years. The object of any investigation at the present time

must be to determine the wisdom or unwisdom, the necessity or lack of necessity, of this law. In effect the law was condemned eighteen years ago by the joint commission of American and British experts of 1896-7. The following words from the ninth paragraph of their joint agreement are worth quoting:

The methods of driving and killing practised on the islands, as they have come under our observation during the past two seasons, call for no criticism or objection. An adequate supply of bulls is present on the rookeries; the number of older bachelors rejected in the drives during the period in question is such as to safeguard in the immediate future a similarly adequate supply; the breeding bulls, females, and pups on the breeding grounds are not disturbed; there is no evidence or sign of impairment of virility of males; the operations of driving and killing are conducted skillfully and without inhumanity.

This very positive conclusion was reached after two seasons of thorough study, involving the observation and inspection of drives aggregating 150,000 animals, 50,000 of which were killed. The commission of 1914 will have no opportunity whatever to observe the normal methods of land sealing, the law preventing it. The commission of 1896-7 had opportunity to carefully weigh and consider the action of pelagic sealing, in its judgment the sole cause of the herd's decline, determining the proportion of pregnant and nursing females in the catch on board the sealing vessels and observing the starvation of the dependent young on land. The new commission is entirely cut off from this source of information, the treaty of 1911 having suspended pelagic sealing. The new commission can obtain definite information from the rookeries of the present condition of the herd, but it will have no basis of comparison arising from previous experience, and can not, therefore, of itself determine whether the herd is increasing or diminishing.

Another difficulty confronts the new commission. It is said to "have been selected by outside agencies and to have no previous connection with the fur seal controversy." In other words it is a non-partisan commission.

The Secretary of Commerce has, however, taken pains to show that the issue is by no means a non-partisan one. On October 13, 1913, Secretary Redfield appeared before the House Committee on Expenditures in the Department of Commerce and thus expressed himself regarding the law of 1912: "I shall be glad to cooperate in any way within my lawful power or within the scope of my personal ability in carrying out to the spirit and to the letter what I regard as very wise legislation for the protection of our fur-seal herd." He even went further and announced to the committee that he had discharged the chief of the Alaska division of the Bureau of Fisheries and the naturalist of the fur-seal herd, because, forsooth, their "mental attitude" toward this law was not right. In other words, because these men believed the law was a mistake, they were disciplined.

The new commission is therefore in a dilemma. It must find the law of 1912 to be right or else to be wrong. In the one case, in a single season's work and with opportunity to get first-hand information on vital matters cut off, it must either review and turn down the work of an eminent body of men acting on unlimited data, or else it must contradict the expressed belief of the very authority under which the commission acts.

Meanwhile there hangs over the commission and its work a most heavy forfeit. The law of 1912, in so far as it prohibits the killing of male seals, was adjudged unnecessary eighteen years ago; the increase of 12½ per cent. in the stock of breeding seals in 1913, the second season under exemption from pelagic sealing, fully bears out this decision. The Secretary of Commerce has in his possession to-day adequate data to warrant the immediate repeal of the law. Such repeal now would permit of the resumption of normal land sealing in 1914 and the taking of the half million dollars' worth of sealskins which the hauling grounds of the Pribilof Islands stand ready to yield. We lost a like sum in 1913 through the operation of the law. The delay necessary to let the new commission make its report will inevitably repeat this loss. In short, the report of the com-

mission will cost at a minimum \$500,000, fifteen per cent. of which belongs to Canada, fifteen per cent. to Japan, and seventy per cent. to the treasury of the United States, under the treaty of July 7, 1911.

GEORGE ARCHIBALD CLARK

THE PRESERVATION OF ANTHROPOID APES

TO THE EDITOR OF SCIENCE: The suggestion of Professor Robert Yerkes in SCIENCE of May 1, that permanent stations should be established in tropical countries for the preservation of anthropoid apes in order that observations of value from a psychological standpoint be obtained, prompts me to urge the same thing on another and more important ground. As readers of SCIENCE doubtless know, the question of the etiology and the treatment in a number of diseases which have hitherto baffled investigators, probably will depend upon the use of these apes as objects of experimentation, and for this, if for nothing else their extinction should be prevented.

OMAHA, NEB.

SCIENTIFIC BOOKS

- Clean Water and How to Get It.* By ALLEN HAZEN. Second Edition. New York, John Wiley & Sons. 1914. Pp. 181. \$1.50.
Studies in Water Supply. By A. C. HOUSTON. New York, Macmillan Co., Limited. Pp. 193. \$1.60.

These two volumes may well be considered together, for they occupy the same general field, although their scope and method of treatment are quite different. Both authors are acknowledged experts in the subjects with which they deal.

Hazen's book is decidedly American in point of view and makes a strong case for the filtration of public water supplies as a means of protecting municipalities against typhoid and other forms of disease and for the improvement which can be so produced in the appearance, taste and odor of surface waters.

By some, the book will be regarded as too condensed to give a comprehensive knowledge of the many topics dealt with, but the

volume is not intended to be exhaustive. It is such a statement of the essential principles of American water purification practise as Mr. Hazen's large experience as a consulting engineer in this field has led him to believe would be useful to beginners. There is no better text-book for persons desiring a knowledge of water purification in the United States.

There are eighteen chapters in Mr. Hazen's book, including such topics as water supplies from rivers, lakes and wells; the history of water purification in the United States; storage of filtered water; use and measurement of water; suitable pressure to be supplied in water works systems; effect of iron pipes on water, and the layout of works. The subjects dealt with include sand filters, mechanical filters, coagulation basins and aeration.

The book is well-illustrated with half-tones and is produced with the usual excellence of the Wiley press. The first edition, published seven years ago, has been revised and expanded.

Houston, the bacteriologist and director of water examination of the Metropolitan Water Board of London, has produced a book in which he has explained his views as to the extent of the danger to be apprehended from polluted river water and how that danger is avoided without filtration by London, the largest and one of the healthiest cities in the world.

The American arguments which have been built up without opposition in the last twenty years and which seek to account for much of the excessive prevalence of typhoid in American cities as caused by polluted surface water are declared to be inconclusive and not in consonance with ascertainable facts.

Dr. Houston maintains that a watershed may be exposed to manifold pollution and the river draining from it impure, as judged by ordinary chemical and bacterial tests, but the water may nevertheless be shown to contain none, or scarcely any, of the microbes of water-borne diseases when tested by methods of proved value.

The American theory to the effect that the

incidence of tuberculosis, pneumonia and other diseases not otherwise suspected of being water-borne can be greatly reduced by improving a public water supply is incredible to Dr. Houston.

The book is actually, but not formally, divided into two parts: The first tends to free the River Thames and the River Lee, which supply London with 80 per cent. of its drinking water, from the full gravity of the charge of being sewage-polluted rivers, and the second presents evidence that the self-purification process employed by London to prepare the water for consumption is uniformly efficient. There are eleven short chapters. The topics include water and disease; the financial value of pure water; sterilization processes; storage in relation to purification; the question of abstraction; sources of water; bacterial methods and much information about the remarkable water supplies for London over whose quality the author has had official supervision for many years.

GEORGE A. SOPER

NEW YORK CITY

Studies in Seeds and Fruits. An Investigation with the Balance. H. B. GUPPY. London: Williams and Norgate. 1912. Pp. xii + 528.

A careful reading of the research work, detailed in this volume, has abundantly repaid the reviewer. Guppy commenced the investigation, as a study of the rest-period of seeds, using in his research merely a sharp knife, pocket lens, balance and oven. The first chapter details the history of the investigation. The second chapter describes the three conditions of the seed, viz., the soft pre-resting seed, the contrasted, hard-resting seed and the soft, swollen seed on the eve of germination. Observations by means of the balance are made on seeds in all three of these stages. The third chapter is concerned with the impermeability of seeds and its significance, the fifth is a classification of seeds according to their permeability, or impermeability, while the sixth chapter gives additional evidence. The whole book is full of tables and is loaded with

detailed observations on such subjects as hygroscopicity, the régime of the shrinking and swelling seeds, the dehiscence of fruits, the proportion of parts in fruits, the abortion of ovules, seed coloration, the weight of the embryo, the rest-period of seeds and a philosophic chapter (XX.) on the cosmic adaptation of the seed in which the author states his belief that the seed is less specialized and less conditioned than the plant; that its potentialities present us with a range of life-conditions that extends beyond the earth and offers a clue to the conditions of existence in other worlds. Finally Guppy postulates a flora of the cosmos.

Although the author allows himself in the last chapter to be spirited away from things mundane, yet, the whole work is pervaded with the spirit of thorough scientific research in which no fact is overlooked which might bear on the main problem of seed investigation, and each fact is submitted to rigid examination, by the balance and other instruments of precision. The book has been overlooked apparently by other American botanic reviewers and it deserves a place on the shelves of any library that attempts to be stocked with recent important contributions to botanic science.

A NEW MARKING SYSTEM AND MEANS OF MEASURING MATHEMATICAL ABILITIES¹

PERHAPS the most noted methods of measuring the intelligence of young children are the De Sanctis and the Binet-Simon tests. These tests apply mainly to the measurement of lower levels of intelligence. It is very significant that the noted Italian and French psychologists who originated these tests did not extend the general method to be used with pupils of the secondary and higher schools. In the present state of educational psychology

it does not seem practicable or possible to effect successfully such an extension; that is to say, it is improbable that such tests can be devised which can be applied to everyday use in our schools, and will be a real improvement upon our present system of examinations, in settling questions of promotion and in awarding honors in our high schools and colleges. We are able to determine certain questions of athletic proficiency by measuring the high jump or broad jump, by timing the quarter-mile or half-mile run. The fact that the candidate knows beforehand the nature of the test does not materially interfere with its efficiency. But if a candidate for promotion knows beforehand the exact nature of the test in algebra—as he easily may know, if tests are adopted to be used by all teachers at all times—then he can easily learn the few tests and make a high grade, even though his knowledge of the entire subject may be woefully deficient. It is quite evident that it is impossible to formulate specific questions in any branch of high-school mathematics, which could be used everywhere and at all times. Yet the report of the American Committee No. VII. on Examinations in Mathematics contains the following:²

There seems to be a pronounced desire throughout the country for standardized tests in mathematics, that is, tests which will enable teachers to measure fairly accurately the efficiency of their instruction and to know whether their pupils are as proficient as those in other localities.

One way to meet this demand is to prepare a syllabus of essentials in high-school arithmetic, algebra and geometry, to be used in preparing the specific questions for an examination. Such a syllabus has its merits and also its demerits. Its merits are that both teachers and pupils have the territory to be covered by the examination more definitely limited to what are the essentials. Its demerits are that it leads both teachers and pupils to a disregard of the many minor facts of a science, which deserve at least passing notice.

¹ Read before the mathematics section of the Central Association of Science and Mathematics Teachers, November 29, 1913, at Des Moines, Iowa.

² U. S. Bureau of Educ., *Bulletin*, 1911, No. 8, p. 13.

Nor does the use of such a syllabus prevent the selection by one teacher of only easy exercises, and by another teacher of only hard exercises. It is my opinion that the value of a syllabus is overestimated, that our high-school text-books do not differ widely in the amount of material, nor in the degree of difficulty of the exercises contained therein. If a teacher carefully prepares a set of questions which, taken as a whole, are of average difficulty, he may rightly assume that he has a standard test. Notice my use of the word "carefully." No system of marking, however perfect, can be successful, if the teacher does not exercise *care*. A 12-inch disappearing gun will not defend Panama unless there is a careful eye to train it.

Granted that a standard set of questions is at hand, are our difficulties solved? Have we an absolute system of marking? By no means. Every one knows that two teachers seldom agree on the marking of the same examination paper. They differ often by 10 or 20, and sometimes even by 30 points on the scale of 100. Suppose a pupil in algebra makes a mistake in algebraic sign, but otherwise answers a question correctly. One teacher will attribute the error to mere oversight, and mark the question nearly perfect. Another teacher will be horrified at the ignorance of fundamentals, and will mark the same question nearly 0. Such discrepancies will arise even in the use of the Binet-Simon system. That system does not eliminate the lopsidedness of the examiner. One of the questions put to a child of ten is this: "What would you do if you were delayed in going to school?" Various replies may follow, as, for instance, "I would have to hurry," "I would have to run," "I would return home," "I would be punished," "The teacher would slap me," "I would not do it again." Do you believe that in such a variety of answers which children may give, any two examiners would agree in their markings? "I would be punished" does not answer the question. Accordingly, some examiners would mark 0. Other examiners would say that the reply not only implies that the question was properly understood, but that

the child's mind passed beyond the immediate reply, that it "would have to hurry," and gave expression to a possible consequence that was more remote and therefore indicative of greater intellectuality. The diversity of estimates would be as conspicuous here as in any ordinary examination. As yet we are as far as ever from an accurate standard of marking.

But a more or less absolute standard of marking is the very thing we are after. We need a common mode of procedure, such that a mark of "excellent" in first-year geometry, given by a teacher this year, means nearly the same thing as a mark of "excellent" in this subject that will be given by a teacher twenty years from now. We need a system of marking such that a mark expressed in numbers conveys to every one a fairly uniform and definite idea of proficiency. During the last few years great progress has been made in devising plans toward achieving this end. What I shall present to you to-day contains little that is novel. In this matter I follow in the foot-steps of Cattell,³ Colvin,⁴ Dearborn,⁵ Finkelstein,⁶ Foster,⁷ Hall,⁸ Herschel,⁹ Huey,¹⁰ Judd,¹¹ Meyer,¹² Sargant,¹³ Smith,¹⁴ Steele,¹⁵ Stevens,¹⁶ Starch¹⁷ and others.

Our scheme of measuring mathematical abilities resolves itself into two parts, as follows:

1. A formula for "arraying" students in order of ability, that is, for determining the relative positions of the members of a class, so as to establish the order of merit, or the rank of each individual in the group. This formula furnishes also preliminary estimates of ability.

2. A revision of these preliminary estimates so as to supplant them by an absolute standard.

Part I

Mathematical ability depends in part upon knowledge of a subject and proficiency in carrying on accurately the mechanical operations connected with it. This kind of ability may be determined by the usual memory tests conducted from day to day in the class-room, and at longer intervals by examination.

Mathematical ability is measured also by the success in solving original exercises. These tests are made in daily work, and also in final examinations.

The observation of instructors and the teachings of the history of science suggest a still further test of mathematical power, namely, the diligence or tenacity displayed by a pupil in pursuing his work. A pupil of only average talents, but of great tenacity of purpose, may achieve more in his life than a bright pupil of limited powers of application. A standard illustration is the case of Robert Mayer, who as a pupil made only a moderate record, but who, by his extraordinary tenacity of purpose was led to the discovery of the law of the conservation of energy.

In Germany and Switzerland this feature is being recognized in the records and reports of scholarship. When I was a boy I received two marks on every subject, one for *Fleiss*, or dili-

gence, the other for *Fortgang*, or progress. In Germany this practise is in vogue to-day.

According to our scheme, the mathematical pupil is measured in three ways, as follows:

1. By memory tests
 - (a) In daily work.....Ma
 - (b) In examination.....Mb
2. By original exercises
 - (a) In daily work.....Oa
 - (b) In examinations.....Ob
3. By diligence (tenacity) shown.... D

How these marks should be combined might be a subject of legitimate debate. Following custom, we use the weighted arithmetic mean, as follows:

$$\text{Preliminary Mark} = \frac{Ma + rMb + sOa + tOb + uD}{1 + r + s + t + u}$$

where r, s, t, u are coefficients determining relative weights. What weight should be given to daily work, what to the examination? In different schools the weights vary from daily work $\frac{1}{2}$, final examinations $\frac{1}{2}$, to daily work $\frac{3}{4}$ and final examination $\frac{1}{4}$. A conservative estimate would be to take $s=1, r=t=u=\frac{1}{3}$.

Part II

After the relative place or rank of the students in a class has been determined by the process of Part I, we proceed to determine their marks on an absolute scale. We shall assume that the pupils constitute a random sample or "fair sample" of the student body. What is the distribution of mental ability, and of mathematical ability in particular? No one has been able to give a final answer to this question. Francis Galton, Karl Pearson and others have held that individuals differ from each other in ability in such a way as to conform with what is known as the "normal frequency curve" or the "normal curve" or the "Gaussian curve." Distances along the horizontal line measure the students' abilities. The corresponding ordinates of this bell-shaped curve indicate the frequency. In measuring physical characteristics, it is easy to tell whether or not the above curve represents the proper distribution. It is a singular fact that this curve has been found to represent a general biological

¹⁵ A. G. Steele, *Pedagogical Seminary*, Vol. 18, 1911, p. 523.

law of variation. Natural phenomena, as well as chance, tend to fluctuate in a manner indicated by this curve. Chest measurements on 5,738 soldiers¹⁸ show the close agreement with theory. The stature of 1,052 English women¹⁹ was found by Karl Pearson to closely obey the Gaussian law. Some of the lower mental traits can be measured in the psychological laboratory. Thorndike²⁰ found twelve-year-old pupils to be distributed according to the Gaussian curve as regards their accuracy and rapidity of perception. Memory tests yielded similar results. When it comes to tests of higher intellectual powers, records are discordant. Different examiners have varied to such a marked degree in marking the same individuals that conclusions can not be safely drawn from their estimates. On account of the presence of constant errors, the lopsidedness of individual markings can not be altogether eliminated by taking the averages of many grades from different examiners. A curve constructed from 1,487 grades in mathematics given by 19 different teachers in three high schools in Colorado exhibits two peaks with a valley between. The first peak is at 70 per cent., the passing mark; the other peak is just above 85 per cent. Evidently the peak at 70 per cent. is due to a constant error arising from the practise of raising marks of some pupils to the passing grade. Such constant errors arise also where a mark of 85 per cent. on the daily work exempts students from final examinations. It is found that in such cases medium grade students are advanced to the exempt limit. Seldom are marks given between 55 and 59, where 60 is the passing grade. If a doubtful student is finally passed, some teachers give him a mark considerably above passing, the idea being²¹ that, if passed at all, he ought to be passed

"handsomely." The tendency to mark high is inherent in human nature. Dr. Ruffner says:²²

A temporizing professor who loves popularity and desires, like the old man in the fable, to please everybody, is sure to be guilty of this fault, and, like many a politician, to sacrifice permanent good for temporary favor.

For these reasons, available statistics as to the distribution of mental abilities are inconclusive. Some empirical curves indicate considerable skewness, others follow the Gaussian curve. President Foster found that 8,969 grades in 21 elementary courses for two years at Harvard obeyed the normal curve of frequency. Dearborn makes similar reports for 472 high school pupils, also for freshman grades of these same pupils at the University of Wisconsin. It is doubtless the principle of continuity that has led not only English statisticians like Galton and Pearson, but also American investigators, Foster, Meyer, Smith, Dearborn, Finkelstein and others, to aver that the Gaussian curve or normal curve is the proper curve for the distribution of marks in school. In what follows we assume that the Gaussian curve can be so used.

The question then arises, what marks should be assigned to a random group or "fair sample" of, say, twenty students, whose order of rank is known by the tests suggested in Part I. This question involves some intricate statistical theory, which has been worked out by Karl Pearson. Pearson²³ states the problem thus:

A random sample of n individuals is taken from a population of N members which when N is very large may be taken to obey any law of frequency expressed by the curve $y = N\phi(x)$, ydx being the total frequency of individuals with characters or organs lying between x and $x + dx$. It is required to find an expression for the average difference in character between the p th and the $(p + 1)$ th individual when the sample is arranged in order of magnitude of the character.

In answering this question, Pearson de-

²⁴ For practical use this table should be considerably extended.

²⁵ The marks for a class of 100 are adapted from the tables of H. L. Moore's "Laws of

Wages," New York, 1911, pp. 98, 99. Moore computed his table to six decimals. He applies Pearson's statistical theory to the study of "wages and ability."

This difference problem marks a new and very probably most important departure in statistical theory.

Clearly a knowledge of the average difference in scholarship of adjacent individuals supplied by Pearson's formulas involves also a knowledge of the average difference in scholarship between any two individuals. We shall display in our tables the difference be-

difference between the tenth and eleventh. Similar statements apply to the poorest pupil and the one next above him. These relations are brought out by the adjoining figure.

Distances measured to the right and left of the zero point signify abilities above and below the modal ability. The relative standings of the members of an average class of 20 are indicated by the dots. Observe the

FIG. 1.

tween the modal or most frequent scholarship of the class and the scholarship of any individual in the class.

The columns headed "mark/s" signify the ability of the pupil above or below the modal ability, divided by s , the standard deviation of the total group of students (say first year high school students) from which the particular class is taken at random as a "fair sample." It will be noticed that a large standard deviation indicates a large range of distribution—that is, a large difference of accomplishment between the best and poorest in the class. In freshman classes the standard deviation is apt to be large, because of great difference in preparation. For our purposes, the exact value of the standard deviation is of no interest. We are concerned more with the ratios of differential abilities than with their absolute values. Hence we shall take $s=1$, or, if more convenient, $s=10$.

Consider a class of 20 pupils. The modal or "mediocre" ability is taken here, as in the other cases, as the standard of reference and is marked 0. Abilities of students are arranged symmetrically above and below, and marked positive and negative. By subtracting the ability of a pupil of rank n from that of his neighbor below, we get the differential ability of the two. In a class of twenty the difference in average ability between the tenth and eleventh pupil is .13. The difference between the first and second pupil is .5. Thus the difference between the first and second pupils is about four times greater than the

denseness of the dots near the modal position and the isolation of those at the ends.

When the number of pupils in a class is larger, the differential ability of the pupils ranking next to each other becomes smaller. Thus in a class of 100, the difference between the first and second is on an average .3, that between the 50th and 51st is on an average .02, but the former difference is about 15 times greater than the second. The importance of these relations is brought out by Pearson in the following words:

It is not possible to pass over the general bearing of such results on human relations. If we define "individuality" as difference in character between a man and his compeers, we see how immensely individuality is emphasized as we pass from the average or modal individuals to the exceptional man. Differences in ability, in power to create, to discover, to rule men, do not go by uniform stages. We know this by experience, but we see it here as a direct consequence of statistical theory, flowing from a characteristic and familiar chance distribution. We ought not to be surprised, as we frequently are, at the results of competitive examination, where the difference in marks between the first men is so much greater than occurs between men towards the middle of the list. In the same way the individuality of imbeciles and criminals at the other end of the intellectual and moral scales receives its due statistical appreciation.

The total range of distribution for classes of random pupils not exceeding 100 is about $2.5s$ on each side of the modal line, where s is the standard deviation. Taking $s=1$ or $s=10$ we have a scale for marking, the objec-

tion to which lies mainly in the fact that it is new. But this scale is the most scientific yet proposed. It is based on careful, statistical theory.

The mode of distribution of mental abilities, exhibited in the normal curve, suggests that the scale be subdivided into an odd number of parts, so that there may be a central group, representing average students, which is the most common type of students. The other groups are placed symmetrically above and below this central group. What should be the total number of groups? Experience shows that three groups are hardly sufficient, that seven groups are excessive. The five-group system is altogether in nearest accord with experience. Accordingly, we shall use the terms "Excellent," "Superior," "Medium," "Inferior," "Poor," and define their positions on the Pearson scale, thus:

Poor	Inferior	Medium
Below — 1.5	— 1.5 to — .5 +	— .5 to + .5
	Superior	Excellent
	.5 + to + 1.5	Above + 1.5

When a class of 20, 30 or 40 pupils has to be marked, we first determine the ranks of the pupils. Then the numerical values of these tables are a suggestion as to the probable marks to be assigned. For any one class of 20 these tabular figures are, of course, not binding. If a large number of different classes of 20 could be marked with absolute accuracy, the averages of the marks of all the pupils that take the rank n in the lists of twenties would yield the values given in the tables. Thus the averages of the students ranked fifth in different classes of twenty students each, is .8. What deviation from the tabular marks should be made in the case of any particular class because of its individual variation or its deviation from a "fair sample" must lie with the judgment of the instructor. The position of the exact line of cleavage between pupils "passing" and those "not passing" must rest with him. It is my own judgment that, if teachers were to follow very closely the tabular marks, and were to modify them in only ex-

ceptional cases, and then only slightly, that a great stride would be taken toward a scientific and absolute method of marking. Gross irregularities in marking, such as Finkelstein has found in Cornell, and such as we know to exist in schools with which we are connected—irregularities working great injustice to pupils aspiring to honors and to scholarships—would be eliminated by the adoption of a plan as herein set forth. Every one knows that the marking system as carried on at present in high schools and colleges is a farce. But the adoption of a scheme of marking as here proposed would show that a mark of 0 places the pupil in a modal position, as a mediocre student. A mark above 1.5 places him in the list of the very few branded "excellent." A mark below — 1.5 places him near the line of students marked "not passed."

In nearly all the marking systems that have been suggested in recent years, the recommendation is made that, under normal conditions, a certain percentage of the class be marked "excellent," another percentage "superior," etc. The Missouri plan involves the same idea by dividing each class of 100 into four groups of 25 students each, and then subdividing the first and last groups again into two classes. I have never seen it pointed out that such a procedure, as a matter of fact, rests upon an unsound basis. The tabular data computed from Pearson's formulas show that if, for instance, we mark 7 per cent. of a class of 100 "excellent," we have a different standard of "excellence" from what we have when 7 per cent. of a class of 50 is marked "excellent." The difference in standard is slight, but it exists, and therefore renders the percentage basis scientifically objectionable. To illustrate: When 7 per cent. of the class are marked "excellent," the lower limit for this mark on the Pearson scale is (using more accurate results than those in our table) 1.4390 for a class of 100, 1.4045 for a class of 50, 1.3951 for a class of 40, 1.3529 for a class of 30, and 1.3080 for a class of 20. Seven per cent. of a class of 41 members is four, but only three of the four stand above the point 1.4390

on the Pearson scale. In other words, on the 7 per cent. basis of excellence, the grade "excellent" is easier to reach in a small class than in a large one. If a class is divided arbitrarily into four groups, equal in number, as in the Missouri system, then the lower limit of merit for the top group is .6588 for a class of 100, .6368 for a class of 40, and .5972 for a class of 20. Twenty-five per cent. of a class of 51 members is 13, but only 12 of these have a mark above .6588 on the Pearson scale. Such variability of standards does violence to our sense of scientific rigor, though the practical results do not usually differ, owing to the fact that in practise only integral numbers apply.

In a scientific marking system the first requisite is uniformity of standards of reference. Lack of uniformity is sufficient reason for rejecting the classification into groups on the percentage basis, as in the Missouri system and others, unless that basis has some advantages which compensate for its theoretical defects. Such advantages it is difficult to discover.

To summarize, our proposed plan of marking is as follows:

1. A system of preliminary marking is used, merely to determine the rank of the students.
2. After the rank is fixed, each student is assigned the marks given in our table, with such slight modifications of the marks as are necessary in the judgment of the instructor.

The advantages of this system are:

1. It rests upon correct statistical theory.
2. The groups called "superior," "medium," "inferior" cover equal ranges of ability. These ranges are constant, no matter what the size of the class may be. Neither the top group called "excellent," nor the bottom group called "poor" has a fixed extreme limit, thereby providing, as the system should, for the grading of men of genius at one end and of the intellectual sluggards at the other.
3. It tends to eliminate the personal equation of the examiner.
4. The method is absolute, except in the determination of the deviations of the marks of a class from the average marks of classes of that size.

"This is a complicated system," you will say. So it is, though not quite so complex, perhaps, as it appears at first sight. Chemists and physicists know that any process of exact measurements requires time, patience and skill. That is true of our plan.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION B—PHYSICS

SECTION B—Physics—of the American Association for the Advancement of Science held its meetings jointly with the American Physical Society during the convocation week beginning December 29, 1913, at the Georgia School of Technology.

Professor Anthony Zeleny, of the University of Minnesota, was elected vice-president of the section for the ensuing year. There were also elected to the Sectional Committee, Professor D. C. Miller, Case School of Applied Science, 4 years, and Professor G. W. Stewart, University of Iowa, 5 years.

As customary in the past all the shorter and more technical physical papers were given under the auspices of the American Physical Society. On the other hand the longer papers, and, in this case, those that dealt especially with geophysical problems, were grouped together and given under the auspices of Section B. These were:

The Methods of Physical Science, to What are They Applicable?: ARTHUR G. WEBSTER.

This was the vice-presidential address, and is given in full in SCIENCE, 39, pp. 42-51, 1914.

The Present Status of the Magnetic Survey of the Earth: L. A. BAUER.

A concise summary was given in this paper of some of the more important investigations undertaken, and conclusions reached, by the department of terrestrial magnetism of the Carnegie Institution of Washington. The great progress of the magnetic survey of the earth, as conducted by this institution, both over land and over water, was shown on a projected map. Many thousands of miles, even hundreds of thousands, have been traversed in obtaining the data necessary to the accurate magnetic mapping of the earth; nor were the routes followed along the safe and beaten tracks of travel, but rather across the least fre-

quented and even the more dangerous regions, and yet, in spite of the great distances travelled and all the excessive difficulties encountered, the entire survey has thus far been made without the occurrence of a single fatal accident.

Isostasy and the Size and Shape of the Earth:

WILLIAM BOWIE.

The determination of the size and shape of the earth would be a simple matter if its geoid or sea-level surface formed a geometrical figure, but as it does not the actual problem is a difficult one. These deviations, it was shown, are due to differences in the vertical distribution of mass in adjacent isostatic regions. When corrections for the effects of topography and isostatic compensation are applied to the astronomically observed positions the deviation of the geoid from the spheroid surface is largely eliminated.

The shape but not the size of the earth may be determined from the observed values of the force of gravity at stations widely separated in latitude. Here again a correction for topography and isostatic compensation is necessary for the best results. Absolute values of gravity can be obtained only with a long series of observations, and therefore nearly all gravity determinations are made by the relative method. Those of the Coast and Geodetic Survey are based on the absolute value at Potsdam.

Investigations made by the U. S. Coast and Geodetic Survey during recent years show that the area of the United States, taken as a whole, is in a state of perfect isostasy, and that areas of limited extent deviate only slightly from that state. The paper will later appear in full.

Seismology: OTTO KLOTZ.

The most improved seismological apparatus, the data obtained by them and the conclusions logically deduced from this data were all discussed at some length. A full and interesting account, together with many illustrations, was given of a recent installation of seismological apparatus that registers in magnified form even those small vibrations of the earth's crust caused by the passage of ocean waves.

The Factors of Climatic Control: W. J. HUMPHREYS.

It was explained that such things as land elevation, oceanic circulation and volcanic dust in the high atmosphere are among the most important factors of climatic control, assuming of course approximate constancy of atmospheric composition and solar radiation.

Both the direct or primary and the indirect or secondary effects of each of these factors were explained in some detail and illustrated by statistical curves.

It is expected that the paper will later appear in full.

There was also one joint meeting with Section C—Chemistry, at which the following papers were presented:

Geochemical Research: JOHN JOHNSTON.

A general account of some of the main lines of geochemical work which are now being pursued in the geophysical laboratory of the Carnegie Institution.

The Ternary System Lime-Alumina-Silica: G. A. RANKIN.

The author discussed the results of an extended investigation of this system, which is important from a geological standpoint as well as from the fact that these three oxides are the essential ingredients in the manufacture of portland cement clinker. The fields of stability of all the substances which may be encountered in this system have now been determined satisfactorily; so that it is now possible to state precisely what happens when any mixture of the above three oxides is heated, and hence incidentally to specify the essential constituents of portland cement clinker.

W. J. HUMPHREYS,
Secretary of Section B

SOCIETIES AND ACADEMIES

ACADEMY OF SCIENCES OF ST. LOUIS

At a meeting held June 1, Professor Nipher gave a brief account of a new method of decomposing water.

A continuous discharge from electrodes in separate beakers was made to pass through a capillary tube, forming a siphon connecting the water in the two beakers, water was decomposed at the electrodes and within the siphon. More than 50 times as much explosive gas was discharged from the siphon as was collected in the tubes around the electrodes. Distilled water which had been freshly boiled was used.

A full account of this result will be given in a volume now in the hands of the publisher, which will give a full account of the results of Professor Nipher's experimental work during the last five years.

Vacuum Thermo-Elements

Made by

Siemens & Halske

The Siemens & Halske Vacuum Thermo-Elements are designed for measuring very small alternating currents, in conjunction with suitable pointer or reflecting Galvanometers. Sensibility is very high, and results of great accuracy may be obtained by their use. These instruments have been used by Public Utilities and Industrial Companies, and in University and College Laboratories. Shunts with several ranges and multi-way switches may be supplied if required.

Write for Bulletin 335, giving full particulars.

Longmans' New Books

Rivers and Estuaries ; or, Streams and Tides

An Elementary Study. By W. HENRY HUNTER, M.Inst.C.E., M.Am.Soc.C.E., Consulting Engineer to the Manchester Ship Canal, etc. With 8 diagrams. 8vo. \$1.00 net. (Weight 12 oz.)

A study of the natural forces to which rivers and estuaries owe their being and their form, and of modern examples of engineering works carried out for the regulation of the features which result from the operations of these forces ; as well as for the improvement of the rivers, in respect of flood discharge and navigation.

Theory and Calculation of Electric Currents

By J. L. LACOUR, Vesterås, and O. S. BRAGSTAD, Trondhjem. Translated by STANLEY P. SMITH, D.Sc., Assoc.M.Inst.C.E., A.M.I.E.E., London. With 404 diagrams. 8vo. Pp. xii+482. \$5.00 net. (Weight 50 oz.)

Mechanics of Particles and Rigid Bodies

By J. PRESCOTT, M.A., Lecturer in Mathematics in the Manchester School of Technology, and Assistant Lecturer in the University of Manchester. With 219 diagrams. 8vo. Pp. viii+536. \$3.50 net. (Weight 38 oz.)

In this book there are chapters on Elasticity, Bending of Beams, the Problem of two or more Bodies, and Spinning Tops, as well as a short appendix on Conic Sections. It contains about 600 examples, many of which are culled from University and other examination papers, and the answers to the questions are given.

Leitz Research
Microscope Stand
"AA" with New
Rotary Mechanical
Stage and
Apochromatic
Objectives.

For Research

Leitz Apochromatic Objectives

[in conjunction with]

Universal Microscope Stand "AA"

A microscope equipped for "critical" work should be available in every research laboratory.

The Apochromatic Series of Leitz objectives is now constructed under a revised optical data and found to excel all others in flatness of field, high degree of color correction and resolving power. Subjected to critical examination and comparison, they are selected by the Government Research Laboratories and for Research in the Leading Educational Institutions.

Our Universal Microscope Stand "AA" has been adopted as Standard for research. This microscope features the Leitz side fine adjustment, recognized as the most sensitive, at the same time proving greatest stability. Our New Rotary Mechanical Stage is supplied for critical research and photo-micrography, making Stand "AA" to represent the highest type of Research Microscope obtainable.

*Electricity has rung the death knell of the
unsatisfactory gas-heated copper oven*

The 'Varsity Electric Oven

With Regulator. Price \$30.00 net

(PATENT APPLIED FOR)

Designed to meet the need of an inexpensive satisfactory electric oven for university and college laboratories requiring a number of ovens to replace the unsatisfactory gas-heated copper ovens, the use of which is rapidly passing.

Constructed for long service
*The only low-priced students' oven
that has no parts unsuited to severe
laboratory usage.*

Specifications

Size of chamber:—10 x 12 inches.

Range: A few degrees above air to 150°C.

Construction:—Of heavy asbestos wood with cast aluminium frame and door; cast aluminium racks allowing the perforated aluminium shelves to be placed at any desired height. Easily removable and correctly wound heating plate. Metallic regulator holding temperature to within a degree. Electric lamp to indicate when current is made and broken.

IMPORTANT BOOKS IN SCIENCE

Artificial Parthenogenesis and Fertilization. By JACQUES LOEB, Member of the Rockefeller Institute for Medical Research.

This new work presents the first complete treatment of the subject of artificial parthenogenesis in English. It gives an account of the various methods by which unfertilized eggs can be caused to develop by physicochemical means, and the conclusions which can be drawn from them concerning the mechanism by which the spermatozoon induces development. Since the problem of fertilization is intimately connected with many different problems of physiology and pathology—we need only mention the natural death of the egg cell and the prolongation of its life by fertilization; the fertilization of the egg by foreign blood and the immunity of the egg to blood of its own species; the relations between heterogeneous hybridization and artificial parthenogenesis, between fertilization and cytolytic, and between permeability and physiological efficiency of acids and bases, etc.—the bearing of the facts recorded and discussed in the book goes beyond the special problem indicated by the title.

318 pages, 12mo, cloth; \$2.50, postage extra (weight 36 oz.)

Animal Communities in Temperate America. A Study in Animal Ecology Designed to Serve as a Reference Work and Textbook. By VICTOR ERNEST SHELFORD, of the Department of Zoölogy in the University of Chicago.

This volume presents the principles of field ecology, illustrated by the more widely distributed animal habitats of the eastern half of temperate North America, and the aquatic habitats of a much larger territory. Six chapters deal with general principles. In several chapters the animal communities are considered from the point of view of modern dynamic ecology. A valuable feature of the book is the three hundred figures of widely distributed animals chosen to represent the chief types of animal communities and their characteristic modes of life.

380 pages, 8vo, cloth; \$3.00, postage extra (weight 44 oz.)

Marine Biological Laboratory Woods Hole, Mass.

INVESTIGATION Entire Year

Facilities for research in Zoology, Embryology, Physiology and Botany. Seventy-six private laboratories, \$100 each for not over three months. Thirty tables are available for beginners in research who desire to work under the direction of members of the staff. The fee for such a table is \$50.00.

INSTRUCTION July 1 to August 11, 1914

Courses of laboratory instruction with lectures are offered in Invertebrate Zoology, Embryology, Physiology, Morphology and Taxonomy of the Algae, Physiology and Ecology of Marine Strand and Bog Vegetation. Each course requires the full time of the student. Fee, \$50.00. A lecture course on the Philosophical Aspects of Biology and Allied Sciences is also offered.

SUPPLY DEPARTMENT Open the Entire Year

Animals and plants, preserved, living, and in embryonic stages. Preserved material of all types of animals and of Algae, Fungi, Liverworts and Mosses furnished for classwork, or for the museum. Living material furnished in season as ordered. Price lists of Zoological and Botanical material sent on application. State which is desired. For price lists and all information regarding material, address

GEO. M. GRAY, Curator, Woods Hole, Mass

The annual announcement will be sent on application to The Director, Marine Biological Laboratory, Woods Hole Mass.

THE PROSPECT OF HUMAN PROGRESS¹

My principal purpose this evening is to invite you to look forward to the time to come and to enquire as to the prospect of human progress which is thus opened to view. But it will be necessary to give a great part of our attention to the past in order to build, as it were, a lookout from which we can obtain a vision of the future.

We shall not be so rash as to attempt a prediction of events or even of discoveries; but we shall try to determine the sort of progress which the indications of the present and the teachings of the past lead one naturally to expect. This will certainly be a safe procedure, provided that we can find common elements of fundamental importance in the basic characteristics of each period; for it can hardly be supposed that the future will suddenly depart from the principles of progress which have been impressed upon the race throughout its long period of evolution up to the present.

It will be necessary for us to pass in rapid review the great stages of development by which man has changed from a beast-like savage to a cultured civilian. We shall find that these stages have been marked off by a few leading inventions, each of them giving a fundamental new element to the period of progress following its appearance. In this review we shall be guided primarily by the researches and conclusions of ethnologists.

It is probably impossible to conceive of man existing as man and not having the elements at least of language for intercourse with his fellows. Therefore, by com-

¹ An address delivered to the Graduate Club of Indiana University on the evening of May 7, 1914.

mon consent, it has been supposed that primitive man was in the possession of spoken language, developed to such a degree as to enable him to communicate effectively with his associates.

A moment's reflection will be sufficient to bring to mind the immense importance of language to any animal fortunate enough to have found, by chance or otherwise, a means for its development. He has for the first time, in the words of his language, a sort of concrete receptacle for his thoughts. Prior to the acquisition of this tool for thinking, his thought had been, as it were, a fluid stream from which he could take up and hold permanently only that which would adhere to a sieve dipped into the stream. He could not give his thought objective existence as standing out before him. He could only feel its passage as it was driven through his mind by one impulse after another from his material environment. But with language at his disposal the case becomes different. Between the language and his thought there is a mutual reaction; and by means of the former the latter is deposited so that it may become the subject of objective study. The immense impetus which this would give to the development of the intellect must be apparent to every one.

There is another and greater element of development in the invention of language, namely, that which is associated with the power of intelligent intercourse. By its means our primitive man has become able to live in part outside of himself and in the thought of others. Thus he can project into himself the experiences of many other persons. This gives a new richness and a new meaning to his life. He is no longer confined to the range of his own experience as his means of development. All his contemporaries, so far as he knows them, can be made to contribute to his progress and be

themselves gainers in the act. And even more than this is true: the experience of one generation can be passed down by tradition to the next. Thus the cumulative effect of the progress of one generation after another first became available to our primitive ancestors. It gave a great impetus to progress.

Indeed, it is true, I believe, that man has not yet taken another step of advancement of as great importance to him as this first one; and consequently I have dwelt on it at some length. It is also to be contrasted, as you will see, with the greater part of his later progress. For, it is essentially intellectual in its character, whereas much of the other depends for its value on the increased control which it gives man over his material environment.

The next stage of development was brought in, it is supposed, by the discovery of the uses of fire. The knowledge of fire is so widely distributed that it is a question whether any authentic instance is on record of a tribe altogether ignorant of it. By means of its use man became able to leave the tropical parts of the world and to go into the more invigorating temperate climates. He also had an enlarged and more nutritious food supply, owing to the increased value of many meats and vegetables on being cooked.

The next prime invention appears to have been that of the bow and arrow. Its chief contribution to progress is also in the increased and improved food supply which it made available. A tribe using the bow and arrow could have meats at all times. Such a diet probably contributed to increase the physical vigor and the courage of the savage possessed of it for the first time. The primitive tribes of Australia and Polynesia had not advanced to this stage when they were discovered a few generations ago.

It appears to be the general opinion that each of the three stages brought in by the three discoveries and inventions named endured for a long period of time, perhaps for something like one hundred thousand years or longer. In all of these stages our ancestors were yet in the savage state. The advance to the higher state of barbarism was brought about by the marvelous discovery of a means of making pottery. Man learned to fashion moist clay into a useful shape and burn it into hardness so that it would endure use. The vessels so constructed afforded him a means of boiling his meats and vegetables so that many of them became highly palatable, whereas they were almost or quite inedible when merely roasted before a fire.

Man, having advanced thus far, was still in a very unsatisfactory state when viewed from our present organization of communities with fixed abodes. He was necessarily nomadic. If he settled down to live permanently at a given place, then the animals, upon which he depended so largely for food would soon disappear from that vicinity both because he destroyed them and because he excited fear in them. But after a time he found means for overcoming this difficulty. Doubtless it had proved profitable, to both the men and the dogs, for the two to hunt together. Thus the dog came to be domesticated. When the idea that captive animals could be of service was clearly conceived, it was an easy step to the domestication of the sheep, the ox, the camel, the horse. Thus man came to have a meat and milk supply readily procurable at all seasons; in addition, he had in the horse and the dog valuable assistants in the chase. As his animals required pasture he came naturally to recognize the value of an increased yield from the soil. Thus, from being a herdsman, he gradually developed into a husbandman.

Then he came to have fixed abodes, and the idea of nationality began to take definite shape.

At this stage of development man had no very effective tools. Wood and bone and chipped flints were the materials out of which were made such as he had. Presently some one made the master discovery of the art of smelting iron. From this time forward man was equipped with tools worthy his hand and his brain.

This invention brought in the last of the three periods of barbarism. Each probably extended over many thousands of years. During these periods man had leisure for the development of his artistic sense; and the way in which he used this leisure is indicated by the remains of his art which have endured to the present day—such as the wonderful paintings found in numerous caves in Europe.

The age of civilization, properly so called, was now brought in by an invention comparable to that in connection with which man emerged as man from his previous savage state. That early advancement, you will recall, was associated with the development of spoken language. The new age of civilization was brought in by the acquisition of written language.

From this time forward progress has been much more rapid than previously. The first stage of civilization extended over the period from the invention of writing to the close of the so-called middle ages, when a new stage was brought in by the invention almost simultaneously of gunpowder, the mariner's compass, paper and the printing press. Coupled with this was the scientific discovery and the demonstration by Copernicus that the sun and not the earth is the center of our planetary system.

These inventions and discoveries brought about simultaneously three fundamental revolutions in human thought and human

relations. By means of gunpowder the peasant became a match for the bravest knight, so that the latter could no longer trample over the former in safety. The castle of the lord no more could serve as a certain stronghold against danger. Gunpowder became a mighty leveling influence and began to prepare the way for equal rights to all men. Through the use of paper and the printing press books were soon widely distributed among a large class of people whereas before they had been the luxury of a few rich nobles. The advances in astronomy turned men's minds upside down, as it were, and set them to feeling that all conceptions of the world and of man were in need of fresh examination and possibly fundamental revision. Add to this the power of the mariner's compass, which enabled men to sail in safety across unknown seas, so that the whole wide world was about to come under their dominion. You can not fail to see that all these things, thrown as they were at once into experience, would undoubtedly produce a profound stir and commotion in the human mind. Such was the state of experience and such were the means of development in the middle stage of the higher civilization.

A period characterized by so much activity would naturally be one of rapid change. You would therefore expect it not to last long. Such indeed was the case. Only about four hundred years had elapsed when, towards the close of the eighteenth century, James Watt gave to the world the perfected steam engine. A new tool of power was thus in the hands of the men of that and future generations. It increased the working speed manyfold and thus brought in a period characterized by greater leisure for the cultivation of those elements of civilization not directly connected with obtaining a food supply. Man

then entered upon the present stage of civilization, the highest to which he has yet attained.

We have now passed in rapid review the elements of the material basis for the progress of mankind. We have necessarily considered only the greatest outstanding facts. Now I should like to ask each of you to take these facts and to build them into a lookout from which to view for a few minutes the prospect of human progress. Or, if you prefer a different figure, will you consider these as constituting a mirror in time by means of which you can see in the past and the present the image of the future, just as by means of a mirror in space you see an extended image in one position while its object is in another?

In the first place, let us ask in what way these inventions and discoveries may be looked upon as the cause of progress. A cause may operate in two very different ways. If a ball is fired from a rifle the explosion of the powder *impels* it into motion and drives it forth. There are other causes in operation; but this is the fundamental impelling one. On the other hand, if the same ball is held at some height and the support is removed, it will also be set in motion. Undoubtedly the taking away of the support is one of the causes of this motion. It is not, however, the impelling cause; it is one acting by release.

If, now, we consider the means of progress we have mentioned, we can find no power in them through which they could have been the impelling causes of human progress. They undoubtedly operated by way of releasing the activity of man. We must assume, then, that there was a power of development inherent in human nature and that these inventions and discoveries merely released that power into activity. That appears to be the teaching of the whole of human progress. It is illustrated

also in the development of the individual. It is clear that the environment is not creating the growing intellect; but it is serving as a means of release to set free its activity and is thus making possible its attainment of power. The fire which lighted the savage's camp in the woods also kindled the intellect of the man who operated with it. It gave him new things to consider. Ultimately it put new tools into his hands and finally it has led his descendants into their most remarkable inventions.

These considerations make it clear that we shall have a fundamental understanding of progress only when we take into account the intellectual and moral and spiritual forces which are released or developed from age to age. These things are elusive; it is hard to get a grasp of them. They have in them the fluidity of life and they slip through our fingers so that we can hardly hold them. And yet they have doubtless had a profound influence of their kind, especially upon the relation of man to man. Consider, for example, this one command, "Thou shalt love thy neighbor as thyself." T. H. Green remarks that this has not varied in form during the whole of human development but that there has been a profound change in the answer to the question, Who is my neighbor? As our conception of duty and one's responsibility to his fellow has widened, we have given a broader and broader answer to this question, so that now every member of the human race is to be considered as our neighbor. Indeed, we have gone further than that and have come to include within the pale of our brothers even the most remote tribes of men. Obviously, this conception, moral or religious in character, must exercise a profound influence on the civilization of the future. Likewise other matters of this sort must have their impor-

tant places; and we will give a just reflection of progress only when we take them into account.

In this connection I must call your attention more precisely to the interplay of material and intellectual forces. We have spoken of the former as releasing the latter. To stop here would be to give a very partial view of the situation. As soon as the intellect has come into play material things will be put into juxtaposition which are not found so in a state of nature. Thus the mind is able to release material forces which had not been in evidence before. These in their turn stimulate the intellect to a greater activity and thus increase its powers. Then we have new juxtapositions of natural things brought about through the deeper insight of the mind into the relations of phenomena. The connections which are thus put in evidence become more and more profound until at length we find man able to control the elusive electricity and by its means to transmit great powers of nature into his homes and his shops, subdued and taught to do his labor for him at his bidding. There seems to be no limit to the progress which may be engendered by this interaction between material and intellectual forces.

Of a similar character, but still more profound in its effect, is the quickening due to the intercourse of man with man. It was this, as we have seen, which characterized the first period of human development. One can not doubt that it has played a fundamental rôle throughout the whole range of progress.

It has been observed many times that a new vigor of character is produced by the intermingling of different races or nationalities of peoples at corresponding stages of development. The new is stronger than either of the elements which go into it.

There is a mutual stimulation which carries them into greater power than either could have attained alone. It is like the production of certain alloys where the mixed metal is much more useful than either of its constituents. The combination possesses properties which do not seem to be in either of the elements combined. It is this intermingling which gives to the character of colonial peoples that remarkable virility which it is often observed to possess. It is this which throws back from the colonies such an influx of power into the mother country. We shall get a picture of how all this is so if we consider the human race to have had at first certain potentialities of development and each group to have lost or to have weakened certain of these while developing others to a considerable or to a vast extent. What we get, then, by the intermingling of these different peoples is the reuniting of these various potentialities, in their developed and strengthened form, so that we come to have in a single individual a combination of elements of power which could be brought to him only by the junction of divergent streams of progress.

Looking at the matter thus we see strong grounds for optimism as to the prospect of further development. Never before in the history of the world has there been so much amalgamation of peoples as at the present time; and consequently there has never before been such an opportunity for reuniting the potentialities which have developed along divergent lines. There is greater facility of travel; means of communication have increased to a remarkable extent; and nations and peoples begin to exhibit a spirit of cosmopolitanism, so that the feeling of world citizenship is coming to play an effective part in the affairs of commerce and government. There is growing up also a demand for a universal language to facilitate intercourse; but what

this will result in one can not at present predict with confidence.

World-wide intermingling of peoples carries with it, no doubt, its characteristic attendant dangers. The various local civilizations which were developed in earlier times, such, for instance, as those of Greece and Rome, ceased to flourish when their central populations became stagnant through the lack of accretions from without. It appears that one line of development can not continue indefinitely unless the potentialities which the people lose in their progress are supplied to them again by another people who have retained what the former had lost. Therefore, if the whole world should become a single community with a single life, we should have only one line of development in progress and hence should naturally suffer in the end a resulting stagnation.

This, however, is probably a danger which should not be anticipated. Though the whole world may be brought very close together by the present tendencies of civilization, it can hardly be supposed that it would grow into a single people with a single life. Such a thing has hardly yet taken place in England after a thousand years of close association on the part of peoples which were descended from a common stock not far removed. Furthermore, if any one should feel that there is ultimate cause for alarm in this matter, the problem could yet be safely left to the future for solution. We may be confident that it will be dealt with in a wise manner when it arises. So many new influences are now coming into play and so many lines of progress are converging into a great central stream that it would be hazardous to undertake a suggestion as to how this problem could be dealt with. It is a question for the future and the future must answer it.

Will you allow me, now, to turn abruptly

to an examination of these chief elements of progress from a different point of view, one which more precisely characterizes the outlook of the man of science? It is this latter point of view, I believe, which is most suggestive of the prospect of progress lying out before us.

If we look at those general elements which have characterized the principal stages of development—those, namely, of savagery, barbarism and civilization proper—we shall find that they are marked off by certain leading conquests, as follows:

During the period of savagery man was winning his way to a partial conquest of the world in the large. At its beginning he was confined to a relatively small portion of the earth's surface, namely, to the more tropical parts. This was true for two reasons: he had not yet discovered means to protect himself against the more rigorous climates; he also required to remain in a region where a food supply was available throughout the year. During the period, however, he acquired the control of fire and invented the bow and arrow. He thus became able to take care of himself throughout a much wider portion of the earth's surface, thanks to his increased control over material things.

In the next period, that of barbarism, he began to bring under his control the animal, vegetable and mineral kingdoms. The animals were taught to do his work and were kept also for a food supply. He learned to cook vegetables so as to render them much more palatable. Furthermore, he acquired the use of iron. In all this, you will observe, he was still dealing with things in the large.

During the next period, that of civilization proper, there was the first adumbration of a control of things in the small; but it was only an adumbration. It is the energy of molecules which gives to the

steam engine its power; but this engine deals with them in the mass and not in the small. So has it been in the control of electricity attained during previous generations; men have not dealt with it in the small.

Thus, throughout all progress until the time of the last generation, it has been true that the conquests of men have been over things in the large.

There is strong reason to believe that we are now entering upon a new stage of progress brought on by the mastery of things in the small. I shall indicate briefly some of those over which we are now gaining such control.

We are no longer content to study electricity in the large; we have chased it down to the electron and probably even to the sub-electron. We are thus in a position to get a fresh insight into its phenomena. We have studied the various rays, visible and invisible, which are produced by the discharge of electric particles; and by means of them we have learned to photograph the bony framework and even the soft organs of the living human body. Here we have begun a conquest which we hope to carry on to many fundamental results.

Ordinary matter also is yielding up to us a more profound secret than we have ever before brought to light. This began with the study of emanations from radium and has been continued with a number of other substances. Furthermore, we have been able to strike off from atoms of various kinds the electron itself and have thus disclosed the intimate kinship of elements which previously had been considered entirely distinct. Here again we have just begun a conquest which we hope to carry on to many fundamental results.

Our men of science have also entered into the living organism and have begun to

study the basis of life itself. Witness the frequent investigation of living cells and even the elements, such as chromosomes, of which these are composed. Here the researches of Mendel and his followers come into play, revealing to us a new means through which we may hope ultimately to control even the character of those yet unborn. Here also we have just begun a conquest which we hope to carry on to many fundamental results.

There is one other mastery over things in the small to which I wish to call your attention, one having in it a great power for the development of strong and vigorous human beings, ready for the further advances of the future. I refer to our new and increasing knowledge of disease-producing germs. Here also we have just begun a conquest which we hope to carry on to many fundamental results.

Thus there has been opened to us in a short space of time a varied and undreamed-of world in the small over which we are now to gain the mastery. Our analysis of previous progress shows that we have here something vitally new. It should therefore lead to important development. Our confidence in this is great, since a little reflection on the matter brings out the fact that we now have converging into one main stream many of the elements which have characterized previous progress.

The actual development which we thus anticipate will be realized only if science indeed makes the conquests which seem to lie out before us. Why, then, may we feel sure of such advance? Time will allow only a brief answer. A slight examination of the past will put in evidence the fact that the fundamental discoveries of the earlier ages came about mostly by chance. Men were not seeking systematically to know the secrets of nature. They learned a few things in a haphazard way. They

had not found out how to make a systematic and all-embracing search through fields either old or new. Fresh discoveries continue to be made right up to the present and with greater speed than ever before. New sorts of questions are asking for an answer. This indicates that the undiscovered regions yet to be found are vast in extent. To-day an increased number of persons are seeking the new. They have learned better methods of research and are able to go about their problem in a more systematic way. Undoubtedly there is still in human character the potentiality of great power to be released through the excitement of new discoveries. Therefore one can not fail to have the best of confidence that there is a long and important line of advancement now to be followed out.

Thus we have at hand every means of progress. The prospect is a pleasing one. He who works at this builds something into all subsequent human development. This is a labor worthy the mettle of the noblest intellect. The science of to-day is lighting the way of progress; and every real contribution to its results will make brighter the illumination of the future. I congratulate you that you have entered upon this labor. May the flower of science blossom at your touch and the vine of knowledge bear luscious fruit under your hand and the pure wine of its vintage flow forth to swell the stream of progress.

R. D. CARMICHAEL

DEFINITENESS OF APPOINTMENT AND
TENURE¹

THE college professor is rapidly being forced to occupy a new and important position in our public affairs and is receiving more of the

¹ Delivered before the College Section of the Association of American Agricultural Colleges and Experiment Stations, Washington, D. C., November 13, 1913.

recognition which his profession has long enjoyed in the older countries of Europe. A university professor who rose from the ranks occupies the White House; another is a prominent member of his cabinet; and large numbers of college and university professors are prominent in the direction of municipal, state and national affairs. This new appreciation of the teacher and the failure of some governing boards to understand their relation to him have led to a considerable discussion of his academic position from various points of view. Much of this discussion has centered around the matter of his tenure of office. Tenure is, of course, affected by the definiteness of the appointment, including its phraseology, and may be affected, though not necessarily so, by the method of appointment, which may vary widely without prejudice to the incumbent's tenure. Furthermore the method of retirement for old age by retiring allowances or pensions may have an important bearing, but need not be discussed after the very full presentation of this matter by Dean Davenport.

Although there has been considerable discussion of specific cases in which the matter of tenure has been involved, broad statements dealing with present customs and determining principles are few in number. The only satisfactory discussion I have found is that of President Van Hise² before the Twelfth Annual Conference of the Association of American Universities at the University of Virginia in 1910. In this address President Van Hise fully described the practise of the universities which are members of that association, and so clearly stated the principles which should govern that there seemed to be a general concurrence in his views. That association, however, includes only 22 of the leading American universities offering graduate work, 9 of which are not state-supported institutions, and only

7 are members of this body. It was evident, therefore, in order adequately to discuss this problem as it pertains to the land grant colleges, that facts must be secured concerning our present customs and the views of our members. Hence a questionnaire was sent to the presidents and deans of agriculture of all the land grant colleges. The replies received from forty-three institutions seem to justify the following statements.

Only eight institutions use definite forms for notices of appointment. Appointees are notified by the president in nineteen states, in ten by the secretary of the governing board, in two by both the president and secretary, and in one by the university treasurer. A formal acceptance is required at three institutions, sometimes only of instructors, and two use a written contract signed by the president and appointee. The time or conditions of tenure are specified in the appointment in nineteen institutions, and are not thus specified in ten. Duties are specified in the appointment in five institutions and merely by the title of the position in sixteen. In several colleges duties are thus stated if special reasons make it necessary.

The replies to the queries concerning the manner of appointment are neither conclusive nor illuminating, except in showing that there is no general usage and that it seems to be usually considered of but little importance. This is evidenced by the fact that in several institutions the appointee may be informed simply by word of mouth. Furthermore, some of the replies are evidently inaccurate, for some institutions state that they specify the time or conditions of tenure in their appointments which, as a matter of fact, do not do so. It is interesting to note that the few institutions which use formal appointments and are most definite in the form thereof are among those generally recognized as best administered and those which are most lax in this matter are among the smaller institutions. The most usual procedure is for the president to write the appointee that he has been elected to a certain position, naming the title and salary, and the date effective. It is usually stated

² Van Hise, C. R., "The Appointment and Tenure of University Professors," *Journal of Proceedings and Addresses of the Twelfth Annual Conference of the Association of American Universities*, pp. 50-61; also in *SCIENCE*, Vol. XXXIII., p. 237.

that the time of tenure and the duties involved are "understood" by both parties. The writer is convinced, however, that in most cases a definite statement of these matters is desirable in the appointment. A university president recently remarked that some one had said that all college presidents are liars. Obviously this exaggeration is due to the fact that no president, dean or director can remember all the "understandings" necessary to manage the affairs in his charge. The more business that can be done in writing the better, as is shown by the general practise of large business concerns. Doubtless railroad presidents would find it difficult to operate their roads and might also become eligible to the "Ananias Club" if they depended on "understandings" instead of written letters. In many cases this lack of definiteness in appointment is due to the fact that the institution has no generally established and generally understood policy concerning these matters, a situation which makes a system of definite appointment all the more necessary.

Furthermore, the appointment should state the principle and essential duties of the appointee. Usually the title of a full professorial position will be sufficiently indicative. If, however, an appointee is to be engaged in the college, station and extension work, or in more than one line, the appointment should clearly state the facts. Is it fair to appoint a man to an indefinite position and then expect him to do whatever sort of work he may be assigned, for some of which he may be poorly fitted, though otherwise well qualified? Should he be asked to change his line of work unless a new, definite and acceptable appointment is submitted to him? The by-laws of one institution states that "any teacher can be called upon for other duties without additional pay." Instances are not uncommon where dissatisfaction has arisen owing to assignment to work of a kind not contemplated by the appointment or previously "agreed upon." The replies to the questionnaire as to the appointment of professors for an indefinite or specific term were as follows. Twenty-two institutions appoint for an indefinite term; seven

use a probationary period of one year and two or three years, followed by indefinite tenure; eight appoint annually, but claim the custom of reappointing during efficient service—a policy often expressed by formal resolution of the governing board so as to be equivalent to indefinite tenure; two appoint strictly annually, and one uses "either" method. In a few institutions professorial appointments are "permanent." If this phrase—permanent tenure—implies tenure for life or until old age retirement, it is much better than the term "indefinite," which really means nothing. Associate professors are usually given the same tenure as full professors, except in three institutions wherein appointments are made for definite terms of from one to five years. The institutions appointing annually, with a probationary term, and for indefinite tenure, do not form any natural grouping or classification. Only two of the ten making annual appointments are among our larger institutions and in these appointees undoubtedly enjoy indefinite tenure, though technically appointed annually. The nine institutions wherein probationary appointments obtain are widely scattered and are relatively small colleges. In practically all of the larger institutions professors enjoy indefinite or permanent tenure upon the first appointment.

In reply to the question whether all faculty members were appointed annually and whether such a system was opposed or favored, from the ten institutions wherein the system of annual appointments is in vogue only two writers favored the system, while three opposed it and five were silent. Thus there is practically unanimous opposition to annual appointments and commendation for the system of indefinite or permanent tenure, at least after a probationary period. The questionnaire elicited opinions to the effect that annual elections cause restlessness; deter strong men from accepting places subject to annual election; discourage loyalty to the institution; are commonly perfunctory; and create an uncertainty incidental to changes in the personnel of the governing board. One replies

that inasmuch as college salaries are relatively low owing to the assumed permanency of tenure, that it must therefore be guaranteed as a matter of justice. Another cites fifteen years of unsatisfactory experience with annual elections. Only two correspondents favor annual elections, one of whom says, "it works no disadvantage" and the other writes,

I favor the system except as to the higher administrative officers for purposes of discipline and good service. I think the administrative officers should be allowed to feel secure in order that definite plans and purposes can be worked out.

There seems, however, to be nearly unanimous opposition to these views.

Several institutions observe annual elections, but practically guarantee indefinite tenure. Thus in Ohio the state constitution prevents any legislature from appropriating beyond its life and the university trustees hold that they can not legally contract beyond their appropriations. Hence appointments are made every year. However, the trustees have also passed a resolution stating that it is their desire that teachers should remain securely in their tenure of office and that the legal annual election was not to be interpreted as any uncertainty of mind on the part of the board of trustees.

Appointments are annual at Cornell University, but

it is the established policy of the university that a man once installed continues indefinitely.

The notice of appointment also states that the salary is contingent upon the appropriations. It will hardly be questioned that at these two institutions professors enjoy permanent tenure, though technically elected annually. However, in some other institutions claiming to employ the same system, the situation is not as clear. One president writes:

All the other members of the staff are technically reappointed for the year when the budget for the coming year is made out. Any one not reappointed at this time (June) is continued on the payroll until the first of September, giving him three months' notice. Usually when the employment of any one is to be discontinued we notify him sometime before June that if the budget is

approved we will not recommend his reappointment.

One can not help but feel that where institutional traditions are not firmly established or where frequent changes may occur in the governing board, a system of annual elections must tend to militate against permanency of tenure and to make removal easier. Even the necessary annual budget may sometimes have a similar effect if the governing board does not clearly understand that its adoption involves merely a statement and not a reappointment. The inconsistency of the policy of some institutions was clearly indicated by one president who stated that his professors enjoyed indefinite tenure, but who held that to terminate a professor's service "he should not be reappointed and the reason should be given him." Boards have been known to secure removals by the simple process of dropping names from the budget.

It is difficult to see just what advantage accrues from or what necessity exists for annual elections. Were the position of the Ohio trustees tenable, most state institutions would be forced to elect annually, for both state and federal appropriations may legally be withdrawn at any time. Is not, however, a professorial position analogous to one held under the U. S. civil service? A civil service appointee enjoys an indefinite tenure during good behavior and is protected against removal except for good cause; but at any time Congress may fail to appropriate funds for a given salary or may abolish a position. Have not the trustees of state institutions the right to make permanent appointments, qualifying them with a statement that in so far as salaries are derived from appropriations they are dependent upon them? Would not such a system conduce to greater permanency of tenure?

Professorial appointments for trial terms of from one to three years followed by indefinite appointment is a different matter and may often be a desirable system. It is evident that our larger institutions can command the services of our best men and can so determine the worth of a prospective candidate as to

leave no doubt of his qualifications for permanent appointment. But at smaller institutions the full professor is often of the same grade as is the assistant or associate professor in the larger ones. It is not always possible to determine his worth or the wisdom of a permanent appointment until his ability is tested. Often young men are chosen who are expected to grow with the development of their departments. A trial alone will show whether they will or will not measure up to the expectations. Hence, a definite appointment for a probationary period, with the possibility of a subsequent permanent appointment is fair both to institution and appointee.

Information was sought by the questionnaire as to the tenure of assistant professors and instructors. Six institutions having indefinite tenure for professors appoint assistant professors for from one to five years and ten appoint instructors for a term of from one to three years. Only eleven institutions have indefinite tenure for all the faculty.

To the question whether short-term appointments for assistant professors and instructors were favored, twenty-two affirmative and fourteen negative replies were received. Most of our larger institutions have found such a procedure advantageous. Some of the comments on this matter are of interest. Dean Davenport, of Illinois, states that instructors being young men should move about from one institution to another, in order to gain experience and to work for advanced degrees; but that assistant professors only occasionally should be short term men, more particularly when they are first given responsibilities involving a good deal of trial. He remarks that sometimes when men are made assistant professors that they stop growing. President Hill, of Missouri, replies:

It seems to me that the appointment for short terms is desirable until the efficiency and prospects for growth of an instructor or assistant professor are pretty clearly indicated. I take it, however, that there will always be some assistant professors in an institution who have already demonstrated their efficiency, but whom the administration is not yet ready to recognize as permanent members of

the teaching force, preferring to see them first make good some of their promises in teaching and research.

These opinions seem fairly to voice the views of the majority, some of whom point out that short appointments of instructors encourage them to do graduate work.

It would seem that although a few institutions elect their professors annually, nearly all consider the term of the full professor as indefinite or permanent, at least after a probationary term. This being the case, the question of terminating the tenure of a professor arises. Three causes, viz., old age, gross misconduct or general inefficiency, may warrant his retirement. The matter of age retirement and the principles upon which it should be based depend largely upon the resources of the particular institution and need not be further discussed in view of Dean Davenport's masterly review of the subject immediately preceding the presentation of this paper. There would probably be no question as to the propriety of the removal of a faculty member for gross misconduct of such a nature as to make him an undesirable associate or teacher. Cases have occasionally arisen, however, where it has been claimed that men have been removed on account of their economic, philosophic or religious views, as expressed in their teachings. Probably injustice is sometimes done in this regard, but doubtless the aggrieved party has usually been removed more on account of his lack of a proper sense of propriety than because of his expressed doctrines. Undoubtedly we would all agree that absolute "academic freedom" must exist as far as the teaching of truth is concerned.

The really difficult cases are those in which the incumbent is generally inefficient or a misfit, in which it is unnecessary and undesirable to make detailed and definite charges, but in which there is no question that for the welfare of both the institution and the incumbent a severance of official relations is desirable.

With this situation in mind the questionnaire sought information by asking:

If a professor is appointed with an indefinite tenure of office, what should be the method of terminating his position if his services are unsatisfactory, provided there are no specific charges against him?

Nearly all who replied to this question indicated that the president should hold a frank conference with the man and urge him to relocate, and should give him ample time wherein to secure a new position. Replying to the query as to what constitutes such ample time, three favored two months, five three months, two four months, fourteen six months and five a year. Two of our most experienced executives stated that they had found a year too long a period, as it interfered with the work of their institution. Dean Davenport has answered these questions so well that I again quote from his letter:

This is an exceedingly delicate question. It refers, of course, to that kind of lack of success which it is difficult to define and certainly against which specific charges can not be made. Personally I believe if the case is not flagrant and the institution is large enough and strong enough to do it, it is best to supersede the position in some quiet way and by reorganization to push the work ahead without the man. But if the issue must be met squarely, then I believe in doing it by the frankest method possible; namely, by discussing the matter with him and showing him why it is that the university must have a change. I think that in the case of a man's becoming undesirable in a responsible position, the very fact that he has been given this responsible position entitles him to great consideration. It seems to me that the best plan is for the institution and the man alike to understand the situation and both to do what they can to find another position where the man can presumably succeed. I do not mean by this that an incompetent professor should be peddled off on another institution; only this, that if the institution ever gave him a professorship, it must have been for a very good reason and his failure is most likely to be due to changing conditions. Under such considerations it is not difficult to find other places where the conditions are more favorable for good work. Except in rare cases, therefore, I would not make the notice definite, but rather indefinite.

Occasionally a case arises in which such treatment must be followed by definite action.

Sometimes a man refuses to make a reasonable effort to secure another position, even after he has been given ample time to do so. Under such circumstances we doubtless would all agree that it would become necessary to formally request his resignation.

In reply to the query whether under such circumstances the notice should be made a matter of record where it may become public, only four answered "yes," and all other replies were "no." There seems no good reason why such a matter should be recorded as public property unless the man himself makes such action necessary. This simply means that in most institutions such notice should be given by letter from the president and not by action of the governing board, which usually becomes public.

The final question asked whether there is any justification for a new managing board declaring all positions vacant and reappointing whomsoever they see fit. Only two replies indicated that possibly circumstances might arise warranting such action. The other forty replies are so emphatic in their condemnation of such a proceeding that the query might seem useless. However, according to published reports there have been one or two recent cases of such drastic action. Formerly such "turnovers" were much more common. Some of these replies may well be quoted if for no other purpose than to voice the universal sentiment of all college men. One writes:

It is a cowardly way to treat the situation.

President Snyder of Michigan writes:

A new managing board that declares all positions vacant is simply advertising to the world its own inefficiency and lack of appreciation of the great responsibility which has been placed upon it.

President Aleo of Maine writes:

I know of no justification whatever for a new board to declare all positions vacant. It seems to me that such a proceeding will result in chaos in an institution. Certainly no self-respecting man would want a position in a college where such a thing is likely to occur.

President A. R. Hill of Missouri expresses himself as follows:

I can see no justification for a new managing board declaring all positions vacant and reappointing whomsoever they see fit. The appointment by any managing board I regard as a mere formality. The real appointment should always be made by the faculty of the department concerned, including, of course, the president and dean who are members of that faculty, meaning by department, as a rule, what used to be meant by chair. Where the faculty of a school or college is small, as in the case of most law schools, the entire faculty of the school should be consulted. I do not mean that a formal vote of the faculty of the school or department need be taken either in making the appointment or in severing the relationship; but the actual sentiment of the faculty should be voiced in either action and when this is the case the action of the Board who are not educational experts, should be merely formal.

Mr. V. H. Henderson, secretary of the regents of the University of California, says:

For a new managing board to declare all positions vacant and to reappoint whom they see fit, is apt to prove a mistake. A wholesale violence of this sort has been proved by the history of American university life ordinarily to result in weakening an institution and hindering its healthy and normal development. As a matter of university planning it is very much better if a managing board shall not itself be a "new board"—that is to say, the governing board should be made up of a body of men whose terms expire at different times, so that the board shall always contain a considerable proportion of members who are thoroughly acquainted with the work of the institution and sympathetic with the purposes and ideals of American university work.

Mr. Henderson then makes the same point as does President Hill:

In the University of California, all initiative as to appointments, promotions, salaries and changes of title is with the president of the university. He invariably obtains the approval of the finance committee of the regents to the creation of a new position, or to changes which involve increase of expenditure, but the initiative in these matters remains with him and questions of personality remain with him. That this should be the case is an essential for the best success of any educational

institution, whether it be a university or a city school system.

Mr. Henderson strikes at the basis of much of the trouble in regard to tenure. Where governing boards consider it their duty to take the initiative in the appointment or retirement of members of the faculty without the approval of the president, trouble is certain to ensue. With the formation of single boards governing all a state's educational institutions, a system now being tried in several states, this policy becomes all the more necessary, for it will be entirely impossible for members of such boards to have much personal knowledge of the fitness of the candidates.

I have endeavored to present to you the prevailing custom upon these matters in the land-grant colleges. Evidently, there is a considerable divergence of policy among the several institutions, the smaller of which may sometimes need to pursue a somewhat different course from that found satisfactory to those enjoying larger resources. However, it would seem fairly evident that there are certain general principles concerning the matter of definiteness of appointments and tenure which should be observed by all. If these could be clearly formulated by our committee on college organization and policy, and then be adopted by this section, would not such action be of considerable value in encouraging a more uniform practise and be a most welcome support to many of our college executives?

E. D. SANDERSON

COLLEGE OF AGRICULTURE,
WEST VIRGINIA UNIVERSITY

THE PORTO RICO SURVEY

THE New York Academy of Sciences has begun a scientific study of the island of Porto Rico along the lines of geology, paleontology, zoology, botany, anthropology and oceanography. With the assistance of a friend, the academy has voted to expend \$1,500 a year for five years on this work, and cooperation with the academy has been assured by the American Museum of Natural History, the New York Botanical Garden and by scientific depart-

ments of Columbia University, New York University and other institutions. Furthermore, on account of the representations made by the academy through its representatives, Professors Henry E. Crampton and N. L. Britton, the insular government of Porto Rico has made an appropriation of \$5,000 toward the work for the fiscal year beginning July 1, 1914, with the expectation that this appropriation would be repeated on each ensuing four years.

The committee having the work in charge consists of Professors N. L. Britton, James F. Kemp, Franz Boas, C. L. Poor and H. E. Crampton. In furtherance of the project, Professor Crampton visited Porto Rico in December and January and Professor Britton and Dr. Lutz in January and February last, and the work is now well under way. Some of the aspects of the work are as follows:

GEOLOGY

Not much is known in detail about either the geology or the paleontology of Porto Rico, so that the field is very attractive. Much, too, remains to be done on the economic geology of the island. The geological portion of the scientific study of Porto Rico will be begun this summer by Professor Charles P. Berkey, who expects to sail for Porto Rico about the middle of August and to spend a month in reconnaissance work on the island. He will probably be accompanied by some other member of the New York Academy of Sciences. Dr. Berkey plans to cross and recross the island at as many points as are available in the time; to gain a general idea of the run of the formations and collect as many specimens as possible. Next winter and in subsequent seasons the details of particular sections will be elaborated by other workers, and the mineral resources will be specially studied. Attention will also be directed with great care to the fossiliferous strata.

ZOOLOGY

In the department of zoology, the field is wide and varied, and the organisms to be investigated are especially numerous. The work

was begun in January, when Professor Crampton completed a reconnaissance of the island in order to map out the different ecological regions for further intensive study. Dr. Frank E. Lutz was a member of Professor Britton's party which investigated the islands of Desecheo and Mona, as well as certain areas of the main island. His collections comprise 10,000 insects, and notable series of land molluscs and other forms.

During the coming summer Mr. Roy W. Miner will begin the detailed investigation of the invertebrates of the shores and estuaries, especially those of the harbors of San Juan, Ponce, Mayaguez and Vieques. The coral reefs off the southern and western shores will also receive attention. Mr. John T. Nichols begins the collection and study of the fishes of the same regions, working with Mr. Miner so as to correlate the studies in these two fields.

For the study of the rich division of entomology, three investigators will take the field. Mr. H. G. Barber and Mr. F. B. Watson leave New York on July 4, and Mr. Charles W. Leng will go to Porto Rico later in the summer. They will study intensively certain characteristic regions mapped out by Professor Crampton and Dr. Lutz. The entomologists of government institutions are cooperating with the survey in this department of activity.

BOTANY

The botany of Porto Rico is fairly well known along several lines, but much field work is still desirable for satisfactory knowledge of the fungi and the lichens, and additions to the known flora in other groups can doubtless be made by further exploration of regions of difficult accessibility. The reforestation of portions of the island is one of the most important economic problems of the colony. Several of the members of the scientific staff of the New York Botanical Garden have given much time to Porto Rico, and the results of their labors will be used in further research there by them. Dr. Britton visited the island in January and is going there again in August.

ANTHROPOLOGY

The anthropology of Porto Rico offers an attractive field of study not only in the ethnology of the present inhabitants, but also and more particularly along the lines of archeology. Much material has been gathered from the surface, but a broad field is offered in the investigation of anciently inhabited caves and in the scientific working over of numerous kitchen middens.

OCEANOGRAPHY

The oceanographic work falls naturally into two general divisions—physical and biological. In both of these divisions there is opportunity for new and very valuable research.

The physical division should include a study of the tides and of the ocean currents in the neighborhood of Porto Rico. The present tidal data consist of several short and disconnected series of observations—the longest series having been made at San Juan in 1899. Observations of ocean currents are few and crude—those of the *Blake* were obtained by comparing dead-reckoning positions of the vessel with observed positions.

Tidal observations could best be carried on by the establishment of self-registering gauges. These could be established at the principal harbors and continuous records for several months or a year obtained.

Current observations to be of value must be obtained by a properly equipped ocean-going vessel, and such a vessel could obtain in a short voyage results of extreme value. At the same time, the vessel could and should be equipped for biological study—the current observations and the deep sea dredging for animal life going on side by side. For these two branches of oceanographic work a vessel is absolutely essential.

The specimens which are collected will eventually find lodgment in the American Museum of Natural History, except for the "first set" of duplicates. These will be deposited with the authorities of Porto Rico for the inauguration of an insular museum, and the academy's investigators will take particular pains to insure the good quality and extent of this series. EDMUND OTIS HOVEY

THE NINTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY

PROFESSOR PAUL WELDEN, president of the congress, in a personal letter writes as follows:

1. The meetings will be held in St. Petersburg from the 8th to the 14th of August, 1915.

2. Excursions are to be made to Finland, Moscow, Kiev, Baku in the Caucasus, etc.

3. In addition to the usual addresses, systematic reviews of the work in particular fields (with discussions) are to be given by specialists, on the invitation of the committee of organization, to a greater extent than formerly.

4. Particulars as to receptions, entertainments, etc., can only be given later.

5. The question of reduced railway fares on the Russian railroads is now under consideration by the government.

6. No obstacles will be placed in the way of the journey of Jewish chemists to the Congress provided (a) that at the frontier, in addition to the vised passport (requisite for every passenger), cards of membership, signed by the president and honorary secretary of the congress shall be presented.

7. An announcement of the Ninth International Congress in English will be sent in the course of the next few days or weeks to North America and England.

THE RUSSELL SAGE INSTITUTE OF PATHOLOGY

At a meeting of the board of directors of the Russell Sage Institute of Pathology, held in New York on June 5, the following officers were elected:

President, Dr. D. Bryson Delaven.

Vice-president, Dr. Simon Flexner.

Secretary, Dr. Theodore C. Janeway.

Treasurer, Dr. Graham Lusk.

Appointments to the scientific staff were as follows:

Scientific director, Dr. Graham Lusk.

Medical director, Dr. Eugene F. Du Bois.

Chemist, F. C. Gephart, Ph.D.

Assistant, Dr. A. L. Meyer.

Dr. Lusk reported for Dr. Du Bois that 142 observations had been made upon patients and on some normal controls during the past year and a half, using the respiration calorimeter established in the second medical division of Bellevue Hospital. In certain individuals an exact agreement between the actual heat production and the heat calculated from the gaseous exchange during hourly periods, was obtained for the first time in man. In the total of all experiments involving the measurement of 23,000 calories, these two methods of direct and indirect calorimetry agree both in health and disease within $1\frac{1}{2}$ per cent. The investigated cases included nine cases of typhoid during both fever and convalescence, one cretin, seven cases of exophthalmic goiter, one of splenic anemia, another with pernicious anemia, one man with acromegaly, one with hypopituitarism, one with malaria, and one with auricular fibrillation, mitral stenosis and greatly enlarged heart.

SCIENTIFIC NOTES AND NEWS

DR. ROBERT S. WOODWARD, president of the Carnegie Institution of Washington, will give the address on the occasion of the dedication on July 10 of the new laboratory building of the Marine Biological Laboratory at Woods Hole.

THE Croonian lecture of the Royal Society was delivered on June 11, by Professor E. B. Wilson, of Columbia University, on the bearing of cytological research on heredity.

THE Franklin Institute of Philadelphia has awarded its Edward Longstreet medal of merit to Dr. W. J. Humphreys for his paper on "Volcanic Dust and Other Factors in the Production of Climatic Changes and their Possible Relation to Ice Ages," which appeared in the August, 1913, issue of its journal.

THE triennial Parkin prize of \$500 of the Royal College of Physicians of Edinburgh, has been awarded to Dr. Johnson-Lavis for his work on the effects of volcanic action in the production of epidemic diseases in the animal and in vegetable creation, and in the produc-

tion of hurricanes and abnormal atmospherical vicissitudes.

THE University of Manchester proposes to confer the following honorary doctorates of science: Professor W. H. Bragg, University of Leeds; Professor W. J. Pope, University of Cambridge, and Dr. J. E. Stead, Middlesbrough.

PROFESSOR R. G. D. RICHARDSON, of the department of mathematics at Brown University, has been elected to membership in the American Society of Arts and Sciences.

PROFESSOR R. C. ARCHIBALD, of Brown University, has been made a member of the editorial board of the *Bulletin* of the American Mathematical Society. Professor Archibald has also had a book by him on "The Lost Book of Euclid" accepted for publication by the Cambridge University Press.

THE Royal Society of Edinburgh has awarded the Neill prize to Dr. W. S. Bruce, in recognition of the scientific results of his Arctic and Antarctic explorations, and the Keith prize to Mr. J. Russell, for his investigations relating to magnetic phenomena in metals and the molecular theory of magnetism.

PROFESSOR A. W. GOODSPEED, director of the Randal Morgan Laboratory of Physics, University of Pennsylvania, has been granted leave of absence for the session of 1914-15. He leaves with his family for Germany on June 25.

PROFESSOR METCHNIKOFF, of the Pasteur Institute, is to be presented with a memorial volume to celebrate his scientific jubilee and his seventieth birthday.

DR. J. J. STEVENSON, emeritus professor of New York University, was entertained on May 28 at a dinner at Pottsville, Pa., by Mr. Baird Halberstadt. There were present a large number of those engaged in the mining industry, to which Professor Stevenson's researches have so greatly contributed. Among those who spoke were Dr. I. C. White, of the University of West Virginia, and representatives of the

Pennsylvania Geological Survey and of the coal industry.

At the meeting of the Cambridge Philosophical Society held on May 18, as we learn from *Nature*, the following were elected honorary members of the society: Dr. H. E. Armstrong; Professor J. Bordet, the University, Brussels; Madame Curie, the Sorbonne, Paris; Professor F. Czapek, the German University, Prague; Professor T. W. Edgeworth David, the University, Sydney; Colonel W. C. Gorgas, Medical Corps, U. S. A. Army; Professor P. H. von Groth, the University, Munich; Professor Jacques Hadamard, the Collège de France, Paris; Dr. G. E. Hale, director of the Mount Wilson Solar Observatory; Dr. François A. A. Lacroix, Natural History Museum, Paris; Professor C. Lapworth, late professor of geology, the University, Birmingham; Professor H. Lebesgue, the Sorbonne, Paris; Dr. Jacques Loeb, the Rockefeller Institute, New York; Professor Arthur Looss, the Government School of Medicine, Cairo; Professor H. A. Lorentz, the University, Leyden; Professor M. Planck, the University, Berlin; Lieut.-Col. Leonard Rogers, the Medical College, Calcutta; Professor Gustav Schwalbe, the University, Strassburg; Dr. Karl Schwarzschild, the University, Berlin; Dr. D. H. Scott, foreign secretary, Royal Society; Professor E. B. Wilson, Columbia University, New York; A. F. Yarrow, Blane-field, Glasgow; Professor P. Zeeman, the University, Amsterdam. The society will celebrate in 1919 the centenary of its foundation.

DR. W. H. R. RIVERS has been appointed to represent the University of Cambridge at the nineteenth International Congress of Americanists to be held at Washington in October next.

THE HON. Bertrand A. W. Russell, lecturer in Trinity College, Cambridge, has been elected Herbert Spencer Lecturer for the year 1914-15 at Oxford.

SIR JOSEPH WILSON SWAN, known for his important discoveries in connection with the carbon filament lamp, electro-chemistry and

photography, died on May 27, in his eighty-sixth year.

DR. PHILIP HENRY PYE-SMITH, a distinguished London physician and man of science, died on May 23, at the age of seventy-five years.

THE death is also announced of Dr. George Dean, regius professor of pathology in the University of Aberdeen.

THE U. S. Civil Service Commission announces an examination for an assistant physicist, qualified in metallography, to fill a vacancy in this position in the bureau of standards, Department of Commerce, Washington, D. C., at a salary of \$1,400 to \$1,800 a year.

THE magnetic survey yacht *Carnegie* left Brooklyn, on June 8, under the command of Capt. J. L. Ault, for a cruise in the North Atlantic Ocean to Norway (Hammerfest) and Iceland. The vessel will return to Brooklyn again about December 1.

THE schooner *George B. Cluett*, of the Grenfell Association, has been chartered by the department of terrestrial magnetism of the Carnegie Institution of Washington for a cruise to Hudson Bay this summer. The expedition will be in charge of W. J. Peters, assisted by D. W. Berky, and will leave Battle Harbor, Labrador, on July 1.

OWING to the fact that the Cartier celebration will be held in Montreal during the week beginning on September 6, and the resultant congestion of hotel and transportation facilities, the meeting of the American Chemical Society in that city has been changed to September 15-18.

THE seventh congress of the International Association for Testing Materials will be held under the patronage of the Czar of Russia, in St. Petersburg, on August 12-17, 1915. After the congress extensive excursions in the interior of Russia have been arranged.

By the will of Harris Charles Fahnestock, of New York, \$550,000 is bequeathed to New York city hospitals and charities.

THE Council of Mathematical Teachers in New England has recently appointed a special committee on the status and welfare of mathematics in secondary schools, to investigate and report on current criticisms of high school mathematics. The membership of the committee is as follows: Mr. G. W. Evans, Charlestown High School; Professor F. C. Ferry, Williams College; Mr. A. V. Galbraith, Middlesex School; Mr. F. P. Morse, Revere High School; Mr. C. D. Meserve, Newton High School; Professor S. E. Smith, Mount Holyoke College; Miss H. R. Pierce, Worcester High School, and Professor H. W. Tyler, Massachusetts Institute of Technology, *chairman*. Correspondence with persons having special information is invited.

A CONVENTION of Tau Beta Pi, the honorary engineering society, will be held in Ithaca on June 11, 12 and 13. One delegate from each of the twenty-seven chapters and the five alumni chapters will attend. The general program includes business meetings on each of the three days and numerous excursions and social meetings.

As we have already announced there will be held a celebration on July 24 to 27 under the auspices of the Royal Society of Edinburgh, of the tercentenary of the publication of Napier's "*Mirifici Logarithmorum Canonis Descriptio*," the work which embodies the discovery of logarithms. Lord Moulton will deliver the presidential address on July 24; and many distinguished mathematicians, astronomers, actuaries and engineers will make communications on July 25 and 27. An exhibition of calculating machines, apparatus and books, and of objects associated with Napier and the history of mathematics, will be held in connection with the celebration. Immediately following a mathematical colloquium will be held on July 28 to 31, under the auspices of the Edinburgh Mathematical Society. The following courses have been arranged for in connection with the colloquium: Two lectures on Nomography, by M. d'Ocagne, professeur à l'Ecole Polytechnique, Paris; four lectures on Infinity in Geometry, by H.

W. Richmond, King's College, Cambridge; four lectures on Critical Studies of Modern Electric Theories, by E. Cunningham, St. John's College, Cambridge; two lectures on The Solution of Algebraic and Transcendental Equation in the Mathematical Laboratory, by E. T. Whittaker, professor of mathematics in the University of Edinburgh.

UNIVERSITY AND EDUCATIONAL NEWS

AFTER several months' investigation the plan of the presidential commission for national vocational education has been presented in the senate in a bill introduced by Senator Hoke Smith, one of the commissioners. It proposes an expenditure by the federal government of \$1,500,000 next year for the salaries of teachers of agriculture, trade, industrial and home economics. The amount would increase automatically each year until 1924, when the total would reach \$7,000,000. An equal amount must be expended by states. A federal board of vocational education would consist of the postmaster general and the secretaries of interior, agriculture, commerce and labor. State boards of not less than three members each would be provided.

THE Sheffield Scientific School, Yale University, has received a provisional gift from a graduate of \$100,000. This gift is contingent upon the securing of an additional \$100,000; the money to be used for the development of a graduate course of one year, and, if possible, two years, as an addition to the present undergraduate course known as the select course, in preparation for business and business administration.

At the annual commencement of Gustavus Adolphus College, St. Peter, Minnesota, announcement was made of the completion of an endowment fund of \$250,000. The two largest contributors were James J. Hill, of St. Paul, and C. A. Smith, of Minneapolis, each of whom gave \$50,000. On the same occasion Oscar J. Johnson was formally inducted into office as president of the institution.

It is announced that the Carnegie Foundation for the Advancement of Teaching has undertaken to grant pension allowances to the director and faculty of the Carnegie Institute of Technology and also to the directors of the Carnegie Museum and the Carnegie Department of Fine Arts, and such of their curators as do teaching work, under the rules and regulations of the foundation.

THE School of Physiology, presented to the University of Cambridge by the Drapers' Company was opened by Prince Arthur of Connaught on June 9. The cost of the building, with the contribution made by the company towards its equipment, has amounted to £23,500.

ON June 3 the University of Missouri celebrated the seventy-fifth anniversary of its founding. Addresses were delivered on this occasion by former Governor David Rowland Francis, president of the board of curators, Albert Ross Hill, president of the university, the Hon. William Rock Painter, lieutenant governor of Missouri, the Hon. William Prentiss Evans, state superintendent of public schools, Frederick Aldin Hall, acting chancellor of Washington University, David Francis Houston, secretary of agriculture, Harry Burns Hutchins, president of the University of Michigan, and Cassius Jackson Keyser, professor of mathematics in Columbia University. On the following day, President Lowell, of Harvard University, delivered the commencement address, and the degree of doctor of laws was conferred on President Lowell, Secretary Houston, Professor Keyser and Mr. William Mack.

DR. ARTHUR KENYON ROGERS, professor of philosophy at the University of Missouri, has been called to Yale University to succeed Professor William E. Hocking, who goes to Harvard University.

ASSISTANT PROFESSOR WILLIAM D. HARKINS, of the department of chemistry at the University of Chicago, has been promoted to an associate professorship in chemistry.

DR. C. H. SHATTUCK, head of the department of forestry at the University of Idaho, was re-

cently elected dean of the college of letters and sciences of that institution.

MISS JESSIE Y. CAUN, Ph.D. (Columbia), head of the department of chemistry, Rockford College, Rockford, Ill., has accepted an instructorship in chemistry at the University of Illinois.

DISCUSSION AND CORRESPONDENCE

SOVEREIGNS AND THE SUPPOSED INFLUENCE OF OPPORTUNITY

A SERIOUS criticism has been made of my theory that the high intellectual qualities found in royal families are the results of natural and sexual selection and inherent in differences in the germ-plasm. My belief is that differences of opportunity may have played some rôle, but my contention is that all the evidence we possess points in the opposite direction, and the conclusion is that differences in opportunity have been on the whole of comparatively trivial importance.

One of the eight reasons in support of this theory, which I have given in "The Influence of Monarchs" (New York, 1913), page 258, is that "younger sons of kings are not less eminent than heirs to the throne." By eminent I mean of high intellectual grade. For this statement I drew upon statistics published in "Heredity in Royalty" (New York, 1906), page 285, and again here presented in Table I. below.

TABLE I

Grades.....	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	Total
Total number in each grade.....	7	21	41	49	71	70	68	43	18	7	395
Succession inheritors	5	14	26	31	49	38	45	23	12	4	247
Per cent.....	71.67	67.63	64.69	54.67	54.67	54.67	57.57	62.5			

These 395 persons were the 395 adult males 25 years or over who were graded for intellect in "Heredity in Royalty," pages 20-26. About three fourths of these individuals belong as descendants in the direct male lines of families studied. The other quarter enter the lists as ancestors, usually direct ancestors, in the various maternal lines. As far as one

can see from this table there is no tendency for the mentally superior grades (8), (9), (10) to be filled with succession inheritors.

It is thus seen that from 54 to 71 per cent. inherited the succession in the different grades. The upper grades are in no way composed of men whose opportunities were enhanced by virtue of this high position. Thus we see that a certain very decided difference in outward circumstances—namely, the right of succession—can be proved to have no effect on intellectual distinction; or at least so small as to be unmeasurable without much greater data.

The criticism which I have received comes in the form of a private letter from Professor J. McKeen Cattell and is so much to the point that it has called for the reinvestigation which I am here giving. The criticism is as follows:

It seems to me that the figures in your table ("Royalty," p. 285) may be explained by the fact that the monarchs attaining (9) and (10) come from a smaller group than those who are not monarchs. The encyclopedias would note all those attaining ranks (9) or (10) whether monarchs or not. The heredity being the same, the non-monarchs should, on your hypothesis, supply a larger number in these grades. As the monarchs supply one half of the (9) and (10) grades (there appears to be an error in the percentage under (9))¹ it follows that their grade was increased by their office. In grades (1) and (2), on the other hand, monarchs would be more likely to be included than other members of royal families.

It will be at once seen that this criticism is directed towards two points which I had not at that time determined—(1) what are the chances that an adult male member of the families studied will succeed to the throne. In other words, what is the per cent. of sovereigns to non-sovereigns when all adult males are considered? (2) What allowance should be made for the "obscure" princes or sovereigns? How many of these are there and is their presence such as to introduce a significant error?

It is not surprising that one unacquainted with royal genealogies should suppose that

the total number of reigning sovereigns should be less than the total number of younger brothers (non-inheritors of the succession). The House of Hanover in modern England would give one this false impression. Here 20 adult males furnish but 6 reigning sovereigns. But the precise record of all the direct lines included in my study shows that this is a marked exception. On the average a little more than half of the males (who live to be 25 years) have become reigning sovereigns by inheritance. This is due to the fact that, in spite of the high fecundity in royal families, during the period studied, the adult males average only between 2 and 3 (2.33 in Table II.) in each "fraternity." There are many instances where a sovereign succeeds his brother, and this brings the proportion to more than one in two.

The percentage 62.5 for succession inheritors, in the table given above, is somewhat higher than that given for the table below perhaps in part because the table above included maternal grandfathers. These are sometimes of houses of less importance and grandeur than the great houses that form the chief male lines. It is probable that they are not often younger sons, consequently they are more apt to be sovereigns. Be that as it may it makes no difference since an accurate and systematic table is now prepared. These figures which are given below (Table II.) deal with the 832 adult persons who are in the male lines in "Heredity in Royalty." 403 of these are males. 220 or 54.6 per cent. became sovereigns by inheritance. The genealogy which I have used is the exhaustive and authoritative "Genealogie der in Europa regierenden Fürstenhäuser" by Dr. Kamill von Behr. It contains the direct lines of all the "Reigning Sovereigns" families of the present day. These are the same as found in the "Almanach de Gotha," *Première Partie*, but the "Genealogie" of von Behr traces them back as far into the past as possible. Von Behr does not include the non-reigning families, found in the "Almanach de Gotha," *Deuxième Partie*. These mediatized German royal families have the rights of equality of

¹ This is a typographical error. The 8 should read 12.

birth with the reigning sovereign houses, but have not reigned since the Napoleonic era. It is easy to tell the actual sovereigns in von Behr as they are printed in capital letters. These are not always kings; a few are of ducal and princely royal houses, but even here some inherit the succession as sovereigns while others do not. With the exception of Montmorency (6 members) all the persons in the following tables are of strictly royal families.

Of the 403 persons in Table II., 94 are "obscure"; that is, not enough could be easily found out about them to warrant grading them for intellect in a scale of 10. More careful researches than I have yet been able to make, would doubtless reduce the number

TABLE II

	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	
Sovereigns by inheritance.....	5	9	24	23	44	30	39	16	7	4	201
Non-sovereigns....	1	9	9	12	18	22	16	12	6	3	108
Probable distribution of "obscure" sovereigns.....			1	7	10	1					19
Probable distribution of "obscure" non-sovereigns...	1	2	11	20	32	7	2				75
Corrected sovereigns.....	5	9	25	30	54	31	39	16	7	4	220
Corrected non-sovereigns.....	2	11	20	32	50	29	18	12	6	3	183
Per cent. of sovereigns.....	71	45	56	48	52	168	57	54	57		54.6

of the "obscure," but I have always felt that this was not necessary to secure the conclusions which have been obtained. It is not necessary to secure the heredity correlations, and now it appears that the error which this introduces is not significant for the present inquiry. Of these 94 obscure members, 19 are sovereigns and 75 are non-sovereigns. The sovereigns are almost certainly and non-sovereigns probably, not worthy of grades (8), (9) or (10). They would probably form a curve of distribution about the grades (4) and (5). The non-sovereigns would find their center a little higher and spread out a little more. They are approximately arranged in the third and fourth horizontal columns.

Now it can be seen that grades (3), (4), (5)

and (6) as they appear in the uncorrected horizontal columns, at the top of Table II., will stand the introduction of a number of non-sovereigns without diminishing the 54.6 per cent. which is the average. Can these 94 "obscure" members be placed in Table II. without overbalancing the results? The reader will see that they can. For although the 75 "obscure" non-sovereigns count against my thesis, the 19 "obscure" sovereigns count in its favor; and all added together give a confirmatory result. In the previous investigation there were about 62 per cent. in each grade, who were sovereigns; now there are about 54. The truth of the whole matter is, that while there are, in the second research, a large number of (4) and (5) grades among the sons, in the previous research these mediocre persons were represented in the ancestry. The previous statistics could not settle the question of how many there were who were "obscure." The present research does settle the point, since it takes them up one by one and counts them all, in a series of "fraternities" one generation after the other.

Those who look carefully will see that there is a slight tendency for the sovereigns to run to the higher grades, but such a tendency is negligible for two reasons, even if a much larger total should make it exceed the probable error. Those who have inherited the throne must, on the average, have lived slightly longer than those who have not. A long life must favor the chances of inheritance. If the sovereigns have been longer lived, then they have had that much more time in which to distinguish themselves. Another point is that for all forms of genius (painters, poets, scientists, authors, etc.) and for the mentally abnormal as well, it has been claimed that the probabilities favor the firstborn beyond chance expectation. But some of these results have been questioned.

At any rate this does not concern the contention which I have made that there is no marked or easily measurable influence of opportunity on sovereigns, at least as arising from their official position.

Here then is an attempt to measure the rela-

tive influence of heredity and environment, not in a general, but in a special way. As I have been pointing out for several years, "the heredity *versus* environment" muddle can not be clarified except by making everything into problems of differences.

The study of the lower organisms may give for human heredity, very erroneous conclusions. The lower organisms are much more modified by environment than are the higher. If we are to make the science of eugenics accurate and accumulative, we must in every case, first decide what human differences, because of their importance, are interesting; then keeping the heredity factor constant, we should experimentally alter the environmental; or keeping the environmental the same, experimentally alter the heredity.

There can be no general answer to the time-honored controversy; but there may be a special answer to each separate, pragmatically conceived question. There may or there may not be. We can not tell until we try.²

Here it is not a general question whether opportunity has had any influence or not. It is a special one. Have we a right to say that there have been proportionately more great men among kings than among commoners because of the environment of kingship? The answer is that as far as we know at present the differences of environment have had absolutely nothing to do with it.

OCURRENCE OF BACTERIAL BLIGHT OF ALFALFA IN THE SALT LAKE VALLEY, UTAH

THE bacterial disease of alfalfa studied by Sackett¹ in Colorado has already done considerable damage in the Salt Lake Valley,

² For a fuller discussion see "Separating Heredity from Environment," *American Breeders Magazine*, Vol. II, No. 3, 1911, and "The Influence of Monarchs," pp. 227-229 and 290-293.

¹ Society American Bacteriologists, Boston meeting, December, 1909. *SCIENCE*, N. S., XXXI., 553, 1910. Colorado Agricultural Experiment Station Bull. 158, 1910.

Utah. So far as the writer knows, this disease, which is due to *Pseudomonas medicaginis* Sackett, has not been definitely reported from Utah, although Heald² states that "what appears to be a similar disease has also been reported from Utah, New Mexico, Nebraska and Kansas." There is sufficient evidence to warrant the statement that the bacterial blight of alfalfa has been prevalent in the Salt Lake Valley for some time, and, no doubt, the poor stands, as well as the many weak plants, are due to this disease. It is certain that this disease has caused more injury than the crown gall disease [*Urophlyctis alfalfæ* (v. Lagerh.) P. Magnus], recently reported by the writer as occurring in the Salt Lake Valley, and is certainly as injurious as the alfalfa weevil (*Phytonomus murinus* Fab.). In the past this disease has been mistaken for smoke injury due to the smelters, and it has also been reported as "alkali burn." That this disease could have escaped notice is singular, because the symptoms are as definite as those of the pear-blight disease.

The water-soaked, semi-transparent, yellowish to olive-green appearance of the stems, together with the presence of small droplets of a thick bacterial ooze and the weakened and partially drooping plants are the unmistakable symptoms of the disease in the incipient stages. Finally the stems become brownish-discolored or blackened, and very brittle. When the stems are attacked the foliage soon becomes chlorotic, finally turning a dirty white in severe cases. The leaves then become dry and brittle. When small pieces of the tissue of the diseased stems or leaves are mounted in water on a slide, enormous masses of the organisms may be seen by the naked eye issuing from the tissues. There is absolutely no difficulty in securing pure cultures.

The presence of the alfalfa weevil in the Salt Lake Valley is a factor in the distribution of this disease. While it is known that stomatal infections may occur, by far the greater number of infections take place through openings in the epidermis produced by insect punctures and severe frost injury. It has been noted that

² *Phytopathology*, Vol. II, No. 1, page 12.

where the disease is present in a field the greater infection occurs where the alfalfa weevil is also present. This disease is so injurious that fully 80 per cent. of the first cutting may be lost on account of it. However, while the chief damage is usually noted in the first cutting, the plants may be seriously injured in the crowns and roots, thus causing entire plants to be killed.

FURTHER NOTES ON TAMARISK

JUDGING from Mr. Carleton's remarks¹ and the writer's experience *Tamarix gallica* is another of those interesting plants that will grow in very dry as well as in exceedingly wet places. This species is extensively planted at Belle Isle, Vermillion Parish, in the broad coastal marsh of Louisiana. The soil here is always saturated with water and is subject to inundation by exceptional tides. The plant is known as salt-water cedar, and its main use is for firewood. Little of that commodity is needed in this austral locality, and sections of the limbs of *Tamarix*, in size from the thickness of a finger to that of the wrist, answer every purpose. The plants are pollarded and closely pruned but quickly produce a new crop of firewood.

W. L. MCATEE

U. S. DEPARTMENT OF AGRICULTURE,
WASHINGTON, D. C.

A FACTOR FOR THE FOURTH CHROMOSOME OF DROSOPHILA

A NEW character has recently appeared in *Drosophila* in which the wings are "bent." The factor concerned does not fall within any of the three groups of linked factors so far described. There are four pairs of chromosomes in *Drosophila* (without taking into account possible complications of the XY pair). The number of chromosomes now

corresponds therefore with the number of independent groups of factors. The correspondence goes even further than number, however, for the sex-linked group is known to be distributed with the X chromosome, and all the groups correspond in their size-relations with the chromosomes, there being three large groups and one small, just as in the case of the chromosomes. The factor for "bent" forms the small "group" by itself, and accordingly may be considered to lie in the small chromosome.

HERMANN J. MULLER

DICKERSON¹ ON CALIFORNIA EOCENE

Two brief but valuable papers by Mr. Dickerson call attention to the fact that the apathy with which the Eocene of California has been treated since Gabb's time is less on account of any last word having been said on the subject than the overshadowing economic importance of the later Tertiary horizons of the state.

The use of the name Tejon to embrace all the post-Martinez Eocene of the Pacific coast and the recognition of the section south of Mt. Diablo as a standard for this formation can hardly meet with general approval. It appears that this section is composed exclusively of beds belonging to a formation stratigraphically younger and separated from the horizon at the type section in the Canada de las Uvas near Fort Tejon by several thousand feet of strata as well as a considerable time gap.

The writers² have shown that in Oregon and Washington the Eocene may be divided into three faunal divisions, the Chehalis, Olequa, and Arago or Ione formations. The

¹ Dickerson, Roy E., "Fauna of the Eocene at Marysville Buttes, California," Bull. Dept. Geol. Univ. of California, VII., p. 257-298, Pl. XI.-XIV., 1913; "Note on the Faunal Zones of the Tejon Group," *loc. cit.*, VIII., No. 2, p. 17-25, 1914.

² Arnold, R., and Hannibal, H., "The Marine Tertiary Stratigraphy of the North Pacific Coast of America," *Proc. Am. Phil. Soc.*, LIII., No. 212, p. 559-605, 1913.

¹ SCIENCE, N. S., XXXIX., pp. 692-694, May 8, 1914.

Chehalis formation is characterized especially by *Venericardia horni* Gabb, *Meretrix californica* Gabb and an austral flora, the Olequa formation by *Pecten* (*Chlamys*) *landesi* Arn., *Venericardia horni* Gabb, and a tropical flora, and the Arago or Ione formation by *Turritella merriami* Dickerson, a form of *V. horni* with obsolete ribs (variety *aragonia* A. & H.) and a tropical flora.

The Chehalis and Olequa horizons lie in juxtaposition, and constitute the coal-bearing Eocene of western Washington. The upper or Olequa horizon has not been definitely recognized in California, but the lower or Chehalis horizon is the apparent equivalent of the Eocene of New Idria, Salt Creek, Coalinga, Canada de las Uvas, Simi Valley, Topa Topa Mountain, Santiago Canyon, and presumably Rose Canyon near San Diego, as well as the plant-bearing shales near Lake Elsinore.

Looking at a map of the Pacific coast, it is evident that these deposits were formed in two embayments. The Puget Basin covered western Washington from the south base of the Olympic Mountains to the Columbia River, an arm reaching northward to Vancouver, British Columbia, while the main body extended inland to the foot of the here more recently developed Cascade Range and probably farther, for the Swauk formation of central Washington apparently represents deposits formed near the east margin of the same great stretch of marsh and estuary. The Tejon basin covered the San Diego mesa, the Los Angeles coastal plain, and crossed the San Gabriel and Santa Ynez Ranges in a long arm extending into the San Joaquin Valley and northward through the Coast Ranges as far as New Idria. As the deposits are usually more or less marine in origin, it is evident that this embayment was rather of the type of an open roadstead than the partly detached brackish estuary in which the Washington deposits were formed.

The Arago or Ione beds represent a horizon younger than any Tejon recognized in the Tejon or Puget basins. They do not occur in juxtaposition, but are developed in different districts, lying indiscriminately across

older rocks. The Arago or Ione beds have been recognized in three basins, the Crescent basin, a narrow arm extending inland along the north base of the present Olympic Mountains to the vicinity of Port Crescent, Washington; the Arago basin, a broad open roadstead covering the Coast Range, Willamette Valley, and Umpqua basin of Oregon, the marine deposits of the south and west being gradually replaced to the north and east by débris from the Eocene volcanoes of the Cascade Mountains; and the Ione basin which extended inland between the north terminus of the Mount Hamilton Range and the higher Coast Mountains of northern Lake County, to lap the base of the Sierra Nevada. This embayment spread southward through the San Joaquin Valley to Pacheco Pass and San Joaquin Canyon, and north to Oroville and perhaps beyond. Most of the deposits were laid down in a sea of considerable depth as shown by the glauconitic sandstones and the paucity of coal beds, but there is a tendency for the marine beds of the eastern border at Merced Falls, the Mokelumne River south of Ione, and South Oroville Table Mountain to grade up into the rhyolitic tuffaceous plant beds between Ione and Carbondale and at Oroville Table Mountain, while in the district about the Big Bend of Pit River only deposits of the latter type are known.

As already noted, the Tejon type section in the Canada de las Uvas was taken in beds of the Tejon embayment, and since the name Tejon series has always been used in a loose sense the writers have proposed to retain it in such a way as to cover the Chehalis and Olequa formations of the Puget embayment, as well as the deposits of the Tejon embayment.

The Arago or Ione beds, occurring as they do in basins distinct from those in which the Tejon series is developed and being formed at a different period, must be treated as a distinct division of the Eocene. The earlier name is the Ione formation,³ the Arago having been given several years later.

³ The gravels underlying the mud flows of Marysville Buttes often mapped as Ione are of very much later age.

If the section south of Mt. Diablo is considered as a standard for the Ione of California it would be interesting to see whether the divisions admitted by Dickerson may be recognized elsewhere. The series is at many points, especially in southern Oregon, extremely thick, and might easily include more than one faunal horizon as yet unrecognized.

On the whole the writers are in hearty accord with Mr. Dickerson's results. A most valuable point brought out is the discussion of the depths of the water in which the various beds were deposited. It should be the incentive to further studies of this sort which have been altogether too much neglected.

RALPH ARNOLD,
HAROLD HANNIBAL

SCIENTIFIC BOOKS

Artificial Parthenogenesis and Fertilization.

By JACQUES LOEB. The University of Chicago Press, Chicago, Ill. 1913. Pp. viii + 306. 39 tables and 86 figures. Price \$2.50 net; \$2.68 post-paid.

As stated in the preface, "Artificial Parthenogenesis and Fertilization" is in reality the English translation of an earlier work, "Die Chemische Entwicklungserregung des Tierischen Eies," enlarged and brought up to date by incorporation of the recent research in the field of development. The realm of artificial parthenogenesis is not a narrow one, by any means. It involves problems of wide physiological interest, the action of ions on tissues, the natural death of cells, immunity, hybridization and organic oxidation, a process coextensive with life itself. Thus we have chapters devoted not only to the history and methods of artificial parthenogenesis, but on "The Relative Physiological Efficiency of Various Isosmotic Solutions"; "Chemical Constitution and Relative Physiological Efficiency of Acids"; "Condition for Maturation of the Egg"; "Heterogeneous Hybridization"; "Hydrolytic Processes in the Germination of Oil-containing Seeds," etc. The chapters contain a mass of detailed results,

chiefly those of the author, obtained by almost continuous experimentation over a period of fifteen years. Each is a model of what the experimental method should be—the observation of certain facts, the formation of provisional hypotheses to explain these observations and, most important of all, the subsequent testing of the hypothesis by experiment. Only in this way can a mass of unrelated details be welded together into a logical whole presentable to the general reader, as well as the special student of the field of development.

The more recent discoveries are naturally of greatest interest. One is impressed in reading Loeb's book, with the great variations in the conditions for development among closely related forms—variation in factors which we should expect to be fundamental and universal. Thus we find that the eggs of *Strongylocentrotus purpuratus* do not develop in neutral sea water, but only in slightly alkaline sea water, whereas the eggs of *Arbacia punctulata* develop not only in neutral, but even in a slightly acid medium. The response of eggs to different methods of artificial parthenogenesis varies greatly. All gradations occur from species which are normally parthenogenetic or occasionally parthenogenetic through those ready to respond to any method, even mechanical agitation, to forms developing only after very special treatment or not responding to stimulation of any kind.

A similar variation exists in regard to the oxidative process, which is of particular interest for the theory of development. The rate of oxidation in sea-urchin eggs increases sixfold after sperm fertilization or artificial fertilization. Apparently the sea-urchin egg has come to a rest because something inhibits its oxidations and the sperm can set them going again, with consequent development. With this hypothesis in mind we turn to the starfish egg, only to find that here the oxidations do not increase after the sperm has entered. The starfish egg undergoes a certain amount of development, maturation, in sea water and then comes to rest. The entrance of sperm or treatment of some

kind is then required to continue development despite the fact that the oxidations are going on to their fullest extent. That it is their fullest extent is indicated by the interesting fact that even complete cytolysis of an egg by saponin will not further accelerate its rate of oxidation.

Loeb analyzes the effect of the sperm in initiating development into two factors—first, the sperm contains a lysin, not readily diffusible into the egg of the same species, but readily so into eggs of other species, which produces a surface cytolysis. The surface cytolysis leads to membrane formation in eggs which form fertilization membranes as part of their normal development. Foreign cells and foreign fluids may contain similar “lysins,” but eggs are immune to lysins of cells of the same species because they are impermeable to them. Hence they must be carried in by actual penetration of the spermatozoon. In most eggs, especially sea urchins, a second substance must also be carried into the egg to prevent the destructive effect caused by superficial cytolysis. Some eggs, *Asterina*, *Polynoe* and *Thalassema*, do not require the second corrective factor, due possibly to the fact, as Loeb suggests, that they already contain it or automatically form it. Again we note variability in an apparently fundamental point. The effect of the lysin is imitated by the various membrane-forming substances which if too concentrated lead to complete cytolysis of the egg. The effect of the second substance is imitated by the various correcting agencies, hypertonic sea water, low temperature or a prevention of oxidations by KCN and chloral hydrate.

The lysin, the membrane-forming substance, is the essential in causing development. How does it act? At present only suggestions can be made. A possible method and a very simple one would be the removal of some substance which prevents development. This view which has been suggested and discussed by Loeb and other authors seems the most probable one to-day. The problem of fertilization becomes as much a question of what causes the egg cell to cease development in a certain stage as of

the cause for its further development by the entrance of a spermatozoon. In physiological terms we may say that the stoppage of development appears to be due to an inhibiting substance, that it is an auto-narcosis. The lysin in the sperm or any artificial method of causing development, even the prick of a needle, allows the inhibiting substance, the narcotic, to pass out. This result is possibly obtained, although Loeb does not definitely uphold this view, through increase in permeability of the egg. As already mentioned oxidations are not diminished in the resting condition of the starfish egg and it is interesting to note, as shown by Loeb, that oxidations in artificially narcotized cells are likewise not diminished. Narcosis is not due to asphyxiation but is probably due to decreased permeability. Certainly research along the line of cell permeability, especially functionally conditioned changes in permeability is the most promising field for a solution of the problem of development, as of many other biological processes.

The reader interested in developmental mechanics will be well repaid by a close study of Loeb's book. Here is collected in condensed and readable form the results of many years' study together with conclusions and ingenious hypotheses which stimulate to additional discoveries along these and other lines.

E. NEWTON HARVEY

PRINCETON, N. J.

Rocky Mountain Flowers: An illustrated guide for Plant-lovers and Plant-users: with twenty-five plates in color, and twenty-two plates in black and white. By FREDERICK EDWARD CLEMENTS, Ph.D., Head of the Department of Botany in the University of Minnesota, and State Botanist; Director of the Pikes Peak Alpine Laboratory, and EDITH SCHWARTZ CLEMENTS, Ph.D., Instructor in Botany in the University of Minnesota and in the Pikes Peak Alpine Laboratory. The H. W. Wilson Company, White Plains, N. Y., and New York City, 1914. Octavo, 392 pp. (\$3.00.)

Tourists in the Rocky Mountains have waited long for such a book as this, and we hazard the guess that it will be eagerly accepted by them as the manual which will enable them to recognize and name the flowers they find on the high plains and in the mountain canyons. For such people the colored plates of approximately two hundred species, and the black and white plates, of not far from three hundred more, will prove most helpful. But aside from tourists and other summer residents of the Rocky Mountains there is a still larger class of people who will welcome this attractive book. For, contrary to the opinion of many who have never crossed the Great Plains, there are schools and colleges and universities with their students and teachers interested in the plant life about them. And to these we may add an increasing number of people who are interested in plants because they love them. In fact, these great highlands of the United States are coming to contain very many people to whom such a book as this will appeal very strongly. We can not imagine a better book for the high school libraries of the west, or for that matter for the libraries of the western colleges and universities. The beautiful plates, which were made by the junior author, must appeal to every pupil with any esthetic sense, as they must also to many cultured people outside of the schools.

The chief features of the book are its general key to families, in which the treatment is distinctly non-technical, accompanied by a chart of relationship that should make the determination of the family relatively easy. Following these are the Dicotyledonous orders, and families, followed later by the Monocotyledonous orders and families, with keys, again, to the genera, and later to the species. Here a useful feature is emphasized in giving rather fully the etymology of the generic names, a matter that will be appreciated especially by those who are not privileged to be in the classes of scholarly teachers. Each genus is briefly characterized, and following this the species are indicated by a key in which as many descriptive features as possible

are emphasized. In passing it should be pointed out that the plates always include related plants, so that family relationship is thus emphasized. The black and white plates, again, emphasize the more difficult species, notably those of the grasses and sedges. This fact will add much to the usefulness of the book.

An introduction of nine pages gives some idea of "the general lines of the evolution of flowering plants from the ancestral ferns," and suggests "the relationships of the various groups." The discussion leads up to the "chart of relationship" mentioned above.

In the preface the authors have something to say about "species" that will show the scientific reader that they have been thinking of the problem of species limits. Of course this preface was not written for high school pupils, nor indeed for the tourist of limited scientific training, but for botanists this short preface will be found to contain some suggestive thoughts.

We are told by the authors that the range of the book includes "Colorado, Wyoming, most of Montana, northern New Mexico, eastern Utah, and western North, and South Dakota, Nebraska and Kansas," and no doubt it may be profitably used in a considerable area outside of these limits.

The authors are to be congratulated upon the successful completion of this notable work.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

The Life of the Mollusca. By B. B. Woodward. London: Methuen & Co. 1913. 12mo. Pp. xii + 158. Pl. XXXII., 1 map.

This volume is one of a popular series intended to summarize existing published knowledge on the subject of which it treats, and not to present fresh information or new researches. It is distinctly not ecological, and, perhaps in deference to British prudishness, omits the existing data on the reproduction of the pulmonates, a body of facts which have more bearing on the life of these mollusks and have been more thoroughly observed than any other phases of molluscan life.

The plan includes a (somewhat obsolete) system of classification, a chapter on geological history, one on distribution (such as can be obtained from existing manuals), on reproduction (omitting reproductive acts), on food, evolution, instinct, intelligence and uses, with an index.

Taken for what it is, a compilation from the literature for popular use, it should not be too harshly criticized, and in fact presents a useful compendium of widely scattered data, not elsewhere brought together.

It is well illustrated, chiefly by reproduction of the plates of the well-known "Manual of the Mollusca," by S. P. Woodward, first published in 1850, and in its time easily the best of the smaller manuals of the mollusca.

Taking into consideration the purpose of the book, the chief criticism which in justice to the reader we feel should not be suppressed, touches on the too ready acceptance by the author of some statements by others which stand in desperate need of confirmation.

For instance the assertion that the murices utilize the spur or projecting spine of the aperture of the shell to pry open bivalves which they intend to devour, is almost precisely on a level with the statement that a man can sit in his own lap, and would be possible only in space of the fourth dimension. In the most charitable view the author of this assertion united to a lively imagination very imperfect observation. Such notions touch the imagination of the ignorant, but have no proper place in scientific literature.

Also the assertion that the shell-bearing Pteropoda are derived (p. 56) from the *Bulla*-like Tectibranchs (originating with an anatomist of limited experience with mollusks) is hardly compatible with the ascertained facts that shell-bearing Pteropods occur in the Cambrian; while the *Bulloid* Tectibranchs first appear near the close of the Carboniferous (p. 47).

Here and there such questionable statements mar the generally high average of accuracy of this little compendium, but, on the whole, it will fulfil a useful purpose.

WM. H. DALL

PRINCIPIA ATMOSPHERICA

1. *Upper Air Calculus and the British Soundings during the International Week* (May 5-10), 1913. By W. N. SHAW. *Journal of the Scottish Meteor. Soc.*, Vol. XVI., No. XXX., p. 167.
2. *Principia Atmospherica*. A Study of the Circulation of the Atmosphere. *Proc. Roy. Soc. Edinburgh*. Read December 1, 1913.
3. *Principia Atmospherica*. An address before the Mathematical Society, January 7, 1914. Privately printed.
4. *The Interpretation of the Results of Soundings with Pilot Balloons*. *Quar. Jour. Roy. Meteor. Soc.*, April, 1914.

In these four recently issued pamphlets, Dr. W. N. Shaw, the progressive director of the British Meteorological Office throws wide open a new door in aerology through which we seem to catch sight of that great desideratum, the forecast based on definite laws, or perhaps it would be the part of wisdom to say, definite foreknowledge of the structure and energy distribution in "highs" and "lows" in connection with the flow of air at different levels.

It is only a short time since W. H. Dines, studying numerous upper air observations, came to the conclusion that the differences of pressure at the earth's surface were of the same order of magnitude as those at a height of nine kilometers and therefore the distribution must be regarded as controlled by conditions at the base of the stratosphere. In studying this remarkable result, Shaw examined the physical conditions necessary for the building up of pressure between points at the same level in two verticals and found that the difference in the influence of the stratosphere and troposphere is attributable to the characteristic difference of temperature. He establishes a formula for the increase of pressure difference per meter of height and a second equation which gives the gradient wind velocity at any level. This latter is used to explain the variation of wind velocity with height and in particular the falling-off in velocity in

the stratosphere. In the second paper Shaw carries the application of the equations somewhat further and making certain assumptions works out temperature and pressure from wind velocity at successive heights. There is also a statement of certain axioms or laws of motion and applications of the laws in practical meteorology. The laws stated briefly are (1) relation of motion to pressure; (2) computation of pressure and application of gaseous laws; (3) convection, which is expressed as the descent of colder air in contiguity with air relatively warmer; (4) the limit of convection, defined as that portion of the atmosphere where there exists a sensible fall of temperature with height, and (5) the law of saturation.

The irregular variations in temperature-difference as given by a pair of soundings with registering balloons; and the curious local irregularities of wind disclosed by pilot balloon ascents, hitherto explained as uncertainties of observation, are now in Dr. Shaw's opinion seen to be important as indicating complex structure of the atmosphere. If Shaw's reasoning is correct then it may be possible to get from one pilot balloon as much information for practical purposes as from three registering balloons. The distribution of isobars at 4 kilometers as computed by Teisserenc deBort is also considered and the law of convection applied. One sentence is significant and may be quoted. "All the main air-currents of the globe have pressure-distributions to guide them. They can not usefully be called convection currents." There is also a most suggestive reference to the flow of air down the Arctic and Antarctic slopes. It appears likely that whenever in a mass of air, temperature-fall is in the opposite direction to pressure-fall, great change in the horizontal distribution of pressure underneath is the result; and many of our local variations of pressure may fairly be attributed to the reactions which these cold masses of air offer to the attempt (in the end futile) of the upper air to steer them round the pole from west to east. If left to themselves they would circulate in opposition to the circulation of the upper air with which they are in perpetual conflict.

With regard to tropical revolving storms, Dr. Shaw holds that these must be considered under a different head, namely that of turbulent motion, and intimates that papers are forthcoming on this subject.

The third paper is largely made up of tables for facilitating computation in problems like those referred to above.

In the fourth paper our author deals with examples taken from typical cases of atmospheric structure selected by Mr. Cave for illustration by means of photographs of models in the "Structure of the Atmosphere in Clear Weather." Five distinct classes are considered. He introduces a new conception, that of operative pressure. How this is produced does not appear but if its existence be granted and the thermal structure of the underlying air, then the deductions drawn follow with mathematical precision. Instances of irregular distribution of temperature are explained and in the case of one marked inversion it is imagined that the construction was formed above a pool of cold air such as would be found over fog. The result of recent work is to show that as regards the weather of the present and the immediate future, the operative pressure distribution and the thermal structure of the atmosphere between it and the ground ought to be regarded as independent variables.

Shaw looks forward to the issue of maps of the upper levels wherein cloud observations and pilot balloon data will show what the actual circulation at a given level is. From these we may estimate the effect on pressure distribution in lower levels.

The papers taken together give a working plan so far as general atmospheric motion is concerned and form a distinct contribution to the solution of the problem of the life-history of cyclones and anti-cyclones.

ALEXANDER McADIE

BLUE HILL METEOROLOGICAL OBSERVATORY

NAVIGATION WITHOUT LOGARITHMS¹

CAPTAIN GUYOU, of the French navy, a mathematician of note, author of valuable

¹"Nouvelles Tables De Navigation," Emile Guyou. Berger-Levrault, Editeurs, Paris.

works dealing with the problems of navigation and member of various learned societies, has devoted part of his time since his retirement to producing tables from which a "line of position" (Sumner line) can be worked and the ship's position thereon approximately determined with the least labor and in shortest time.

The tables are preceded by a condensed explanation for the benefit of those who wish to understand their mathematical development; but the many practical and efficient navigators who bother little with theory will be interested to know what Captain Guyou does, without having to concern themselves as to how he does it.

Gird up your imagination and conceive the world and the heavenly bodies as standing still; suppose, further, that your ship is connected with a heavenly body not directly overhead—the sun, for instance—by a steel rod having a universal bearing where attached to the ship and another where attached to the sun. Start up your engine and let the wheel alone! The ship will be so controlled by the rod that she must describe an enormous circle on the face of the waters, having for its center that point on the earth's surface at which the sun is then in the zenith. Meanwhile, the rod describes an enormous cone with the sun at the apex, and when we consider that the sun's altitude, or height, is measured by the angle enclosed between the rod and the base of the cone (roughly), we can realize that an observer on board, taking the sun's height with a sextant at frequent intervals, will get the same height all the way around the circle.

The foregoing must be qualified in practise because the world does not stand still and the ship is not going to sail on a circular course; true, she is on the circumference at the moment of observation, but she may be crossing it at any angle because the position of the center of the circle and the direction in which the circumference trends depend upon the sun and not upon the ship.

If the ship be at rest, the observed altitude of the sun will change continually from hour

to hour because of the apparent motion of the sun in his diurnal course. If the ship be in motion, the observed altitude of the sun will likewise change from hour to hour not only because of the sun's apparent diurnal motion, but also, although by a comparatively small amount, because of the fact that the ship is under way pursuing a certain course and making a certain rate of speed. It is evident that she may be considered to be crossing a circumference at any moment and that all sun observations taken at that moment from ships on different parts of that circumference will show the same altitude.

Two problems present themselves!

First: To find the circumference.

Second: To find the point at which the ship was crossing it when the observation was taken.

They have been dealt with in various ways. An able French admiral, Marq de Saint-Hilaire, evolved an admirable solution by working out the distance from the dead-reckoning point—almost always more or less erroneous—to the circumference; his method may be outlined as follows: the navigator measures the height with a sextant, notes the time, then *calculates* the height he would have gotten at the dead-reckoning point at the moment of observation. If the two heights agree the dead reckoning may be accepted as correct, for it coincides with the circumference; this occurs but rarely; as a usual thing the dead-reckoning point falls several minutes (of distance) outside the circle or within it, two heights result, and the difference between them enables the navigator to work out the error in distance from dead reckoning to circumference. This solves the first problem!

The solution of the second is simpler because the dead reckoning is sufficiently reliable to limit to a few sea-miles that portion of the circumference at some point in which the observation must have been taken. Since the circle is very large this small portion of circumference may be accepted as a straight line. It is the navigator's "Line of Position" and the ship's crossing point thereon is closely approximated by the direction of the center

of the circle from the dead-reckoning point, which direction—since the sun is the zenith of the circle's center—is rendered by the azimuth.

But this method, though far the most desirable theoretically, involves the danger of error, the time, labor and irritation inseparable from an appalling array of logarithms—I rejoice that I am not called upon to express the sentiments with which a tired and hungry man in oil-skins regards logarithms—the calculation of height at the dead reckoning point calls for a half dozen, the azimuth for three or four more, and these operations are followed by an excursion into trigonometry to localize the result; which result, if you are an amateur, will doubtless be wrong, while, if a professional, you will not have tried it.

With Captain Guyou's tables one enters with true height and declination in a page devoted to the approximate latitude and takes out two numbers, turns to a page devoted to the approximate hour-angle and takes out two more. With these numbers he does one small sum in addition and and two in subtraction, then rules off the ship's position on the chart.

One can only admire the lofty unconcern with which Captain Guyou juggles distances, especially as he juggles them accurately. One of his circles can enclose the greater part of a hemisphere but he does not hesitate to slide it down until the dead-reckoning latitude coincides with the equator where he performs his mathematical feat with the two heights before coolly sliding the circle back again. Of course the objection at once arises that the navigator would not have gotten the same observed and calculated heights on the equator that he did get in higher latitudes, but here Captain Guyou's versatile resource comes into play, for the navigator *would* have gotten the same number of minutes of difference between the two heights (expressed in minutes of the respective latitudes). This difference, as we have seen above, yields the error in distance between dead reckoning and circumference and from it, in connection with the azimuth, the position can be worked out.

But Captain Guyou does not slide down to

the equator merely in search of the above-mentioned error. He has another purpose and it is indeed ingeniously accomplished: we all know that the basis of navigation is the spherical triangle and that three parts of it—two sides and one angle, for instance—must be known before it can be solved. But tables calling for the combination of three known quantities throughout the extent of 90° of latitude and 360° of longitude would be ponderous and impractical. With only two known quantities these objections do not obtain, but two known quantities do not suffice to solve the problem. In drawing up his tables Captain Guyou has used three, of which the latitude is the third, and has employed a trigonometrical formula in which the required result is obtained by multiplying functions of the two other known quantities by the tangent of one half the complement of the third (the latitude). Since he has slid his circle down until the (dead reckoning) latitude coincides with the equator his latitude is 0° ; the complement 90° ; and the tangent $\frac{1}{2} 90^\circ = 1$, which, as a multiplier, may be disregarded, thus reducing the known quantities which must be considered to two and rendering the tables practicable.

Little knowledge of navigation is required in using them. One must understand reducing observed height to true and correcting the declination for the moment of observation. It is of course necessary to be familiar with the varieties of time used at sea. In figuring, one must know, and observe, the difference between $+$ and $-$.

These moderate requirements can be mastered in a few evenings and practise may then be begun over an artificial horizon, or otherwise, for the tables include a page of directions which cover all cases and can be blindly followed to a correct result. A general conception of the principles of navigation and the problems involved will come with practise and the necessity of thinking out one's mistakes, and, in a short time, a new hand should be able to work at sight with confidence and accuracy.

WALTER D. ROBINSON

SPECIAL ARTICLES

WHAT DOES THE MEDINA SANDSTONE OF THE
NIAGARA SECTION INCLUDE?¹

Most geologists will agree, if stated as an abstract proposition, that a primary essential of any system of formational nomenclature is stability. In concrete examples, however, geologists display a marvelous facility in forgetting the importance of such stability or in ignoring any rules which might bring it about. This is well illustrated by the present status of the term Medina sandstone. In papers which have been read before the Geological Society of America during the last two years not less than three distinct meanings have been given to this term. The inconvenience of having any unit of measure which fluctuates in length from year to year would be no greater than that of using formation names for the geologic scale, which may differ by hundreds of feet in the thickness of beds included, according to the date or the individual author concerned. One can, of course, and in the present chaotic state of geological nomenclature generally does, in using a formation name, indicate whether he accepts Wm. Jones's or John Brown's definition of the formation. He may too have recourse to the booklets of formation names issued at intervals by some surveys, and ascertain what is the most fashionable length during the year in which he is writing for the formation in question. While these are possible and at present apparently necessary methods of indicating what one means when using a formation name, surely it would be better to adhere to a standard definition as we do for such terms of measure as foot and meter. Such a standard definition of a formation, of course, in no way precludes its subdivision as the progress of knowledge concerning it may dictate, accompanied by new names for the new sub-units. In the case of names which seldom reappear in the literature the inconvenience of changing meaning is comparatively small, but fluctuation in the meaning of such a term as Medina

¹ Published with the permission of the Director of the Geological Survey of Canada.

sandstone which occurs in most text-books on geology and in innumerable geological papers must lead to endless confusion. During the last decade a number of papers, perhaps the majority of those dealing with the Silurian of western New York, have made the term Medina include only the 100 feet of beds which are chiefly sandstones immediately preceding the Clinton; the others have included these and 1,100 feet of red shales below them as well in this formation.² Some inquiry into the reason for this wide diversity of usage and suggestions regarding the limitation of this term which the rules of nomenclature seem to indicate appear to be in order.³

These rather surprising fluctuations in the thickness of the Medina sandstone in the same section began with Grabau's⁴ and Chadwick's⁵ proposals to restrict the name to the upper 100 feet of Hall's Medina sandstone, the lower 1,100 feet being named the Queenston shale by Grabau. In raising the question whether there were good grounds for restricting the term to the upper beds to which the sandstone is almost wholly confined, and giving to the lower shaly portion a new name, we are confronted by two subsidiary questions. (1) Is it ever permissible or desirable to restrict or redefine the name of a formation? (2) Was the Jas. Hall usage of Medina sandstone which Grabau's proposal supplanted identical with the application given the name by Vanuxem, who first used it? Examples both of contraction and expansion of the original meaning of formation names might be cited from the papers of various geologists. Whether the practise is approved or censured, there is abundant precedent for emendation of the original meaning of geologic names.

Before considering some of the conditions under which in the writer's judgment emenda-

² Bull. N. Y. State Mus., No. 114, p. 10.

³ The writer wishes to acknowledge the privilege of examining before preparing this paper a manuscript by Dr. E. O. Ulrich which treats, among others, the question here discussed.

⁴ SCIENCE, Vol. 27, April 17, 1908, p. 622.

⁵ SCIENCE, Vol. 28, September 11, 1908, pp. 346-348.

tion is desirable we may revert to the second question. Vanuxem⁶ introduced the name Medina sandstone into the literature in 1840, applying it to beds "called in former reports the red sandstone of Oswego." A much fuller description of the Medina sandstone was given by Vanuxem in 1842.⁷ The formation is fully described in this report from exposures occurring in the Third District of New York to which Vanuxem's work was officially confined at that time. The name Medina which was given to it was taken, curiously enough, from a town about 100 miles west of the western limit of Vanuxem's field of work. Whether we consider the type section to be at Medina or in the third district where the particular section and exposures of the formation described are located, we must go to the latter region to discover just what is included in the term Medina sandstone. It is stated by Vanuxem to include sandstones lying between the Clinton above and the Oswego sandstone below. It is noteworthy that Vanuxem's definition of Medina contains no reference to shale. All of the occurrences of the Medina sandstone which he described in the third district are described as sandstone. The Medina as later defined by Jas. Hall⁸ in western New York is mainly a shale formation comprising the 100 feet of sandstone just below the Clinton together with several hundred feet of red shale lying between this sandstone and the Oswego sandstone. The explanation of this apparent discrepancy between the two definitions appears to lie in the fact⁹ that the upper or sandstone part of Hall's Medina extends considerably further to the east than the lower or shaly part. If Hall's lower Medina (Queenston of Grabau) does not extend as far east as the section described by Vanuxem then the original definition of Medina includes only the upper part of the

beds ascribed to it by Hall, or that part to which this name is restricted by Grabau. Should this inference prove to be true, then Grabau's usage of Medina is really a return to the original meaning and not a restriction of it. In this case then it will be in order to consider whether any good reason can be offered for following the usage of Jas. Hall which makes the term include some hundreds of feet of beds which Vanuxem's definition excluded.

It is proposed here, however, to consider the question on the assumption that the application of the name Queenston to the shaly, and Medina to the sandy part of Hall's Medina was an emendation of the original usage. We may first consider in doing this some of the circumstances which may justify or necessitate emendation of formation names. Under the rules of nomenclature formulated by the United States Geological Survey for the guidance of its members it is stated that "each formation shall contain between its upper and lower limits either rocks of uniform character or rocks more or less uniformly varied in character, as, for example, a rapid alternation of shale and limestone."¹⁰ The application of this rule to the sediments included in Hall's Medina would not permit the use of the name in a formational sense, since the upper hundred feet and the beds below are entirely diverse in character, the latter being almost entirely a red shale, and the former chiefly a sandstone terrane. This lithologic difference between the upper and lower terranes, however, would not necessarily militate against the use of Medina in the group sense. It is in this sense that the name has been used lately by the N. Y. State Geological Survey¹¹ and by the U. S. Geological Survey.¹² There is, however, another and very serious objection to using the term in the group sense. Until recent years the upper and lower divisions of the Medina were supposed to represent the basal part of the Silurian. No

fossils have ever been found in the Queenston division in Western New York, but the discovery of fossils in these beds in Canada has led geologists who are familiar with the evidence to agree that they belong in the Ordovician system.¹³ The fossils which have been found in the Queenston near Collingwood, Ontario,¹⁴ place the Richmond age of the Queenston beyond question. The fauna of the upper Medina, however, as has long been known, places it in the Silurian. It is reported by Williams¹⁵ that evidence in the shape of mud cracks at the top of the Queenston indicate a stratigraphic break between the Queenston shale and the succeeding sandstone which is the Whirlpool member¹⁶ of the Medina. The Medina sandstone of Hall in either the group or formation sense therefore holds the anomalous position of including terranes which are not only unlike in physical characters, but which belong in different geological systems and are, moreover, separated by a disconformity. If beds can be properly kept in either the same formation or group which are so wholly unlike as the Queenston shale and the Medina sandstone of Grabau and which belong in distinct geological systems, then the terms formation and group have no value or definite meaning whatsoever in geology. It is a case where the growth of knowledge has made it impossible logically to hold to the earlier usage of Hall. In the light of present knowledge a restriction of the term so that it will not overlap systemic boundaries appears to be the only feasible method of employing it. Grabau's emendation of Hall's usage accords with the pronounced lithologic features which distinguish the upper 100 feet of the Niagara section from the beds below, and also with the later knowledge concerning the systemic rela-

tions of these beds. This application of the term Medina, which includes the Whirlpool sandstone as its basal member and the Thorold quartzite as its uppermost member, is the usage which the writer believes should and will prevail. The new name Albion which was introduced by the writer in the Niagara Folio¹⁷ is synonymous with Medina as emended by Grabau. The latter term is therefore entirely superfluous and should be dropped from the literature.

Professor Otho Schuchert's recent important discovery, that much of the "Clinton" of the old reports of the Canadian Geological Survey lies entirely below the base of the New York Clinton, must be taken into account in any revision of the Niagara section. Beds in this section which have shown a fauna too meager to encourage special study heretofore, and a lithologic differentiation too slight to appear to merit discrimination as separate members or minor lithologic units have taken on new significance and importance through the work of Schuchert, Parks and Williams in the region west and northwest of the Niagara section. One of these beds contains in the Ontario peninsula a rich and partly undescribed fauna which has been referred to by Schuchert¹⁸ and Parks¹⁹ as the Cataract fauna. The examination by the writer of a number of sections holding this fauna in connection with a review of the Niagara section has convinced him that all of the terranes associated with the Cataract fauna are represented in the Medina of the Niagara section. These have been given individual or member names in recognition of their physical and faunal contrasts by Dr. M. Y. Williams.²⁰

¹⁷ This name was suggested to the writer by the U. S. Geological Survey Committee on geologic names, but since in a Federal bureau suggest and command are convertible terms the writer may reasonably disclaim any responsibility for its use as well as for the usage of Medina there employed.

¹⁸ Paper read before Geological Society of America, January, 1913.

¹⁹ "Excursions in Southwest Ontario," Guide Book No. 4, pp. 127, 134.

²⁰ Paper read before meeting of the Geological Society of America, January, 1914.

Any detailed discussion of the lithologic and faunal characteristics of these several terranes will be omitted from this paper since Dr. Williams will publish this data at an early date. These are indicated in the section given below which includes all of the formations cut by the Niagara Gorge.

NOTES ON A SHEEP THYROID EXPERIMENT WITH FROG TADPOLES

At the time of the publication of Professor J. F. Gudernatsch's paper on thyroid feeding experiments with the tadpole I was working with some tadpoles and having some extra ones I tried a short but similar experiment. I used

the large bull-frog tadpoles which had lain over one winter. The hind limbs had begun to develop and even to joint. They were divided into two lots, the one for control and the other for experiment. The experimental

litherto known as Clinton. Until satisfactory evidence has appeared however, for such revision of the meaning of an old and well-established name there appears to be no reason for seriously considering either this proposed expansion of the term upwards or its expansion downwards as one geologist proposes. Frequent tinkering with the meaning of well-established names is not likely to serve any useful purpose. When revision of a name does appear to be required it should, in the writer's opinion, be accompanied by a full statement of all the evidence in the case and ample time for its discussion should be given before it is accepted. Such evidence has not appeared in this case.

lot was placed in pond water without any food except for such minute particles as may have been suspended in the water. They were fed daily some two grain Parke Davis & Co. sheep thyroid tablets. The tablets were eagerly eaten by the tadpoles and except for appearing rather sluggish their behavior was normal. At the end of seventeen days the hind legs had developed much more and the fore left leg had come through and begun to joint. There seemed to be a slight development of the right forelimb, but it did not come through the operculum. The control lot which had been under the same temperature and light conditions and furnished with plenty of fresh pond water and food showed a slightly increased development of the hind limbs but no signs of any fore limbs. It became necessary at this stage to stop the experiment and the specimens were preserved in formalin. Unfortunately during moving all except a half dozen of the thyroid fed lot and a few of the control were lost, but these have been photographed and are in good condition. I cut open the opercular wall on the right side of one of the thyroid tadpoles and found a fore leg which had begun to develop but was much shorter and less advanced than on the left side where the limb broke through of its own accord. This experiment was too incomplete to have much significance, but it was interesting to note that the right fore limb only completely developed in every case of the thyroid fed tadpoles and in the control lot neither fore leg developed at all. This experiment may be worth while by suggesting more thorough and complete work along this line. It may possibly also be suggestive of a method for right-handed people to become ambidextrous by eating sheep thyroid.

SOCIETIES AND ACADEMIES

THE BOTANICAL SOCIETY OF WASHINGTON

THE ninety-seventh regular meeting of the Botanical Society of Washington was held in the Assembly Hall of the Cosmos Club, at 8 P.M., Tuesday, May 5, 1914. Messrs. P. V. Cardon, G.

P. Van Esseltine and A. B. Clawson were unanimously elected to membership.

The scientific program was as follows:

Professor Chas. O. Appelman, "The Physiology of the Rest Period in the Potato Tuber" (with lantern). To be published as a Maryland State Experiment Station Bulletin.

Dr. H. B. Humphrey, "A Recently Discovered Loose Smut of Rye" (with lantern). To be published in *Phytopathology*.

Mr. L. H. Dewey, "The Common Names of Plant Fibers."

Confusion in the names of textile fibers of vegetable origin causes uncertainty, financial loss and injury to the trade. The name "hemp" and its forms in other languages is the oldest name used to designate a plant fiber. This name is now used in many languages as a specific term to designate the true hemp, *Cannabis sativa*, to which in all instances it was first applied, and also as a generic term to designate all long fibers. This double use is confusing. The name sisal is also being used in a similar double sense. The following suggestions are made regarding the choice of names of fibers: (1) Names in most general use are to be preferred, providing they are not misleading. (2) The same term should not be used to designate fibers from different kinds of plants. (3) One name should be used to designate the fiber from one kind of plant, irrespective of the country where the plant is cultivated, or the manner in which the fiber is prepared. (4) Geographic names are objectionable in general terms. (5) Names that may be adopted directly in all languages are desirable. (6) Single words of not more than three syllables are best.

P. L. RICKER,

Corresponding Secretary

ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At a special meeting of the Society held March 3 at the National Museum, Mr. W. E. Safford read a paper on "The Pan-Pipes of Ancient Peru." Mr. Safford became interested in the musical instruments of the Peruvians during a cruise along the west shore of South America in 1887. At Arica, near the northern boundary of Chile, he found in a prehistoric grave two sets of pan-pipes made of graduated reeds closely resembling the syrinx, or fistula, of the ancient Greeks and Romans. On terra-cotta vases were depicted men playing these instruments. Similar pipes made of bone were also found in Peru and northern Chile. Afterwards an entire orchestra composed of pan-pipes was observed. These were played in pairs, each performer having a mate with a com-

plementary instrument who played the alternating notes of the scale. That the pan-pipes of the ancient Peruvians were thus played in pairs is shown by pictures upon prehistoric vases, in which two instruments are represented as being connected by a long loose string. The pan-pipes observed were in most cases composed of 16 reeds, in two rows, one row superimposed upon the other, the row played upon by the performer having the reeds closed at the bottom, the outer row having reeds with an opening at the bottom. The smallest pair produced shrill notes like those of a piccolo; the largest pair, four times as long, produced deep tones much like those of a barrel organ.

At a special meeting of the society held March 4, at the National Museum, Dr. A. B. Lewis gave an address on his "Travels in the South Seas and New Guinea," illustrated with excellent lantern slides. The four years 1909-13 were spent in the interest of the Field Museum of Natural History of Chicago, studying the natives and collecting ethnological material, chiefly in Melanesia. Many of the islands are only partially explored. Fiji is the most civilized. The natives of Fiji are all professing Christians, and read and write their own language. Except the ordinary things of everyday life, there is little of the old left. The native Fijian population is about 90,000, the European 3,500, while there are 40,000 to 50,000 Indian coolies on the sugar plantations. New Caledonia was, for years, a French penal colony, and the natives are reduced to about 30,000 located on reservations, much as our American Indians. Some of the large islands of the New Hebrides are still wild and unsafe. To the ethnologist, Malekula is the most interesting. Over 20 languages are spoken on this one island, to say nothing of dialects. On the Solomon Islands there are probably not over 300 Europeans. New Guinea is the most interesting island of all. Except Greenland, it is the largest in the world, and the least known. New Guinea has never been crossed except near the ends. More time was spent on New Guinea than anywhere else. A considerable portion of the coast was visited and short trips made toward the interior. There are but few Europeans in New Guinea, the greater number, about 1,000, being in the British portion. A considerable number of these are gold-diggers. In German New Guinea there are about 200 Europeans, and in the Dutch portion not over 50. The old condition of warfare among the natives has been stopped as far as the government can extend its influence.

At the 473d regular meeting of the society, held March 17 in the National Museum, Dr. J. Walter Fewkes delivered an address, illustrated with lantern slides, on his "Egyptian Experiences." He considered especially the significance of certain parallelisms in cultural objects of the Stone Age of Egypt and the Gila Valley, Arizona. These resemblances he ascribed in part to the influence of irrigation. Through the cultural isolation of the Nile Valley in Neolithic times it was protected from outside marauders. Social advancement at the dawn of history was due to the influx of foreign ideas from the east and to the cooperative union of clusters of villages or nomes in order to more effectually irrigate the valley. This cooperation of the rulers of Neolithic Egypt led to the rise of a Great House or Pharaoh. To this cooperation in constructing irrigation ditches may be traced a system of enforced labor in which the Pharaoh not only acquired all cultivated land and the water which alone made agriculture possible, but also controlled all labor of the inhabitants. To these rights acquired from the rulers of the nomes in very early times, may be traced the powers exercised in constructing the magnificent monuments that are the world's wonders.

In Neolithic Egypt, there was a succession of villages strung along the river, each independent of the other, like a cluster of pueblos in Arizona. The remains of architectural constructions at this early epoch still remain and are sometimes, as at El Kab, well preserved. They are rectangular, massive, walled forts with an encircling wall of clay not unlike the compounds at Casa Grande in Arizona. Within these enclosures, in Egypt and Arizona alike, were mud or clay built temples, public buildings and houses of priests, while around them were clusters of the mean hovels in which lived the people like the present Egyptians. The dead were buried in neighboring mounds, placed with knees drawn to the chin and surrounded by mortuary offerings. These graves were rude excavations with floor of straw and roof of mud and boughs. Many resemblances between archeological objects from the Stone Age in Egypt and in the Gila Valley were pointed out. Among these are weapons, stone implements, pottery and its symbolic decorations, flat basket trays, bone and other specimens. Certain common conditions of environment and the necessity for artificial irrigation had led the Stone-Age people of different races, without connections, to develop a parallel culture.

RIES & WATSON—

Engineering Geology

By **Heinrich Ries, Ph.D.**, Professor of Economic Geology in Cornell University, and **Thomas L. Watson, Ph.D.**, Professor of Economic Geology in the University of Virginia, and State Geologist of Virginia.

As far as known this is the only book published which treats geology from the engineering point of view.

The authors have carefully selected their material including the important topics which have to be considered in connection with the study of this subject.

The character of the common rocks in their use for building stone and road material; the structure of rocks in relation to tunneling operations, dam and reservoir foundations, land slides, etc., have been included.

Throughout the book the practical application of the topics treated to engineering work have been emphasized.

An Important New Book in Climatology

The Weather and Climate of Chicago. By HENRY J. COX, Professor of Meteorology, United States Weather Bureau, and JOHN H. ARMINGTON, Local Forecaster. (Bulletin No. 4, Geographic Society of Chicago.)

The importance of this book is indicated by the fact it is issued under the auspices of the Geographic Society of Chicago, and has been prepared by two of the best known weather experts in the country. It includes discussions of a great variety of subjects such as temperature, precipitation, atmospheric moisture, cloudiness and sunshine, wind direction and velocity, barometric pressure, and storm tracks; and among the interesting appendices to the book are one on the weather of holidays and another containing journal entries relative to the Chicago fire of 1871. The book contains also a remarkable series of tables with reference to temperature, precipitation, atmospheric moisture, and atmospheric pressure—one hundred and forty-seven in all, with more than one hundred figures and plates.

The volume, because of its character and authority, will be of great general interest, as well as of especial significance to students of climatology and geography.

396 pages, 8vo, cloth, \$3.00, postage extra. (Weight, 49 oz.)

Of special interest to teachers in connection with **The Weather and Climate of Chicago** is Bulletin No. 3 of the Geographic Society of Chicago entitled **Lantern Slide Illustrations for the Teaching of Meteorology**, edited by Professor Henry J. Cox and by Professor J. Paul Goode, of the University of Chicago.

THE TREND AND INFLUENCE OF CERTAIN PHASES OF TAXONOMY¹

"ENOUGH is sometimes too much," says the newspaper philosopher. I suspect some of you are thinking right now that we have already had enough systematic botany, but as briefly as I can I wish to try to show you that while it is true that we have already had too much, it is equally true that we have had too little.

Do not feel alarmed because of the magnitude of my subject. I shall not deal with it as a whole—only certain phases of it and their influence. Before attempting my main message may I voice a plea for the old-time systematic botany? It is of course primarily the handmaid to all of the other subdivisions of the science, but apart from that is it not in itself a desideratum of no small moment?

It trains the perceptive faculties, teaches orderliness, develops judgment and strengthens reason. It is therefore a cultural course of no small significance to all who take it and, as some of us know, the source of much pleasure to many. There is a saving grace in botany not found in most of the other sciences and this is exercised through taxonomy more fully than through all its other divisions combined. Systematic work for its own sake is distinctly worth while. It develops in the student or the amateur, who achieves a fair measure of success, a feeling of confidence in himself and gives that stimulus for further mental effort that only the conquering of a definite problem affords. In this respect it may be compared to mathe-

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

¹ Read before the Botanical Society of America at Atlanta, December 30, 1913.

matics, with the added advantage that the flavor of the pleasure derived recurs again and again as the fields and woods minister to his life, and spring, summer and autumn, yes, and even winter, in turn speak to him who understands their glad greetings of the passing years.

Let no one imagine that it is merely easy recreation for the *dilettante* in science. It is a man's job. Any one who succeeds in systematic work would measure up well in the philosophical subjects. Manuals and keys can be made only for those who can read as much between the lines as in them; those in whom the power of discrimination becomes strongly developed but who ease up its severity by the due exercise of judgment and reason.

Systematic botany furnishes to the average layman, who is scientifically inclined, a more continuous incentive for pleasurable and inspiring contact with the world about him than any other subject that claims to be worthy of his attention. It may be that it represents the primitive phase of our development, but does not all development begin with the primitive? That some never get beyond the primitive stage is neither here nor there. The same would be found true in any other subject whatsoever. I raise the question if it is not largely true that the best botanists we have or have had began their career as systematists? Were they not led into the subject by this door? Their love for plants, their desire to know them, determined their careers. We may be evolving greater and greater men in the science, but even these must of necessity touch at least the high points in the road by which the race of botanists have attained the crowning glory of the present. The recapitulation theory is as universally applicable as the theory of evolution itself.

Let us look a little farther into the careers of those whose names have come down

from a former generation. To save time we will take a single example, one who was not only a systematist, but the peer of any in his generation in every other line. His name is known to more people in America, even a quarter of a century after his death, than that of any other botanist of any time or place. His bust found its way into the "Hall of Fame" because he did more than any one else to make it possible for people to know plants. He was admired and loved in his day and now because of his "Manual" and the accompanying "Lessons." Let it not be forgotten that he would still have been a distinguished botanist had he given no thought to systematic work. His grasp of structural and physiological problems was far in advance of his time, and who knows whether even his philosophy may not prove to have been more profound than some of his critics will now admit? Dr. Gray found his way into the hearts of the people and enriched their lives by opening for them a larger world than would otherwise have been possible to them.

It is true that in all the botanical fields there are great outstanding characters whom we do not ordinarily think of as systematists. These are, however, men or women who have rendered some signal service to the race by promoting its physical or economic welfare, but even these did much of systematic work before they were able to share with others the results of their achievements. Again, to take but one example, we have in Pasteur a name that will live so long as living things are subject to attack from microorganisms. He made the race his debtor, not only by what he himself achieved in bacteriology, but by opening the way into the new field. The work of his disciples in preventing and alleviating suffering in man and beast must also in part be accounted unto him for right-

eousness. Such men, however, were entering new fields and had to create descriptions and systems of classification as a foundation for their work and as a medium of communication with their fellows. Thus we have come back to the original statement, systematic botany is primarily the handmaid to all the other subdivisions of the subject.

Having said this much in commendation of taxonomy in general, kindly permit now a brief consideration of its trend and influence. If taxonomy and taxonomists are gaining in prestige and power, if the other departments of botany are each year being better served, if the average layman in the field finds it easier to know the plants themselves we may congratulate ourselves and say that all is well. If the reverse is true, something is radically wrong. A cancer is eating its way into a vital part of the body of our science.

Taxonomists were never so numerous nor more active than now. But all activity is not necessarily progress. Motion up and down may be spectacular and nothing more. Never were there so many devoting themselves to this subject professionally as at present. Literature is piling up volume upon volume. Before we can determine whether this is progress or recession we shall have to try to find the purpose of it all. The description and classification of plants is not in itself an end. It is a means to an end and that end not for the specialist himself, but rather for his colleagues in other lines and for the great army of intelligent men and women who love plants for their own sakes.

The reasons why people may wish to know plants are many, most of them entirely worthy. No reason is more legitimate than the mere desire to know that is almost universal until our method of education, or lack of method, kills the de-

sire. Desire that is never satisfied dies afterwhile. The child asks, "What is it?" but when it has received the answer, "I don't know; stop bothering me," seventy times seven its interest either wholly dies or it seeks outlet in other channels. The furore of enthusiasm about nature study I fear has largely spent itself. The best statement of the purpose of nature study that came to me was "It aims to keep alive the child's tentacles of inquiry." Are we not largely failing in the attainment of this meritorious aim? If so, why? As I know our schools it is primarily because of the lamentable ignorance of all nature subjects by the teachers. Not only by teachers in general, but by those professing to teach botany in our high schools. A large majority of them wouldn't know an elm from a holly or an evening primrose from a lily. I have seen them by the score in my state and most of them came from outside schools of high standing where they had been trained in the cytology of plants that they never saw and in the ecology of plants that were left behind in the dreams and environment of yesterday. You may wonder how this relates itself to my subject. But listen! There is no reason for the existence of the professional systematist (apart from the growth and pleasure it yields him personally) unless his efforts produce results that make it more easily possible for others to know the plants in which they become interested. If he fails in this one thing he fails in all. May we not judge by the indifference of the multitude to our work; by the hopelessness of the amateur who tries to acquaint himself with the plants of his district; by the distrust of their results by even professed systematists, and by the none too well concealed cynicism of our colleagues in other lines, that we are failing in this? There seems to be nearly universal agreement

that it has become increasingly difficult for every one, for any one, to state with any degree of definiteness the correct name of any considerable number of plants. That we are in a muddle is evident. That we shall never be able to clear it up I do not believe. I shall not pretend, however, that I am wise enough to tell you how this is to be done. I very much doubt if any one knows at present just what to do next, but at least no harm can come from a free discussion. If we but knew just what has gotten us into our present plight it would simplify matters, but even then the application of the remedy would be difficult. We have each so long been a law unto ourselves that it will be impossible to secure any considerable unity of action at once. Particularly will this be true if there is no agreement that a remedy is needed. Some will feel so, in spite of the fact that a large majority of the botanists of this country would subscribe to the following arraignment: Our work has been analytic, not constructive. We have dismembered organisms and held up to view their component parts. We have been looking for differences and with such amazing success that the fundamental resemblances have largely escaped our notice. We have thus produced a *pot-pourri* that is the despair of every one except ourselves, and most of us do not know how to unravel our own mysteries.

I know this is a terrible charge to lay at our own doors, but perhaps it comes with better grace from one whom others have chosen to consider as *particeps criminis*. I dare not flatter myself that I have been even one of the chief offenders, but I acknowledge with humiliation that I have had a small share in producing the disaster that has overtaken us. I now stand before you thoroughly repentant. Would that I, like the reformed inebriate or the reclaimed

sinner, could preach a gospel of reform with such fiery zeal that I should reach my erring brothers.

I know that only the dead make no mistakes. We have been passing through a period of great botanical activity and he who has not made many mistakes is not much of a botanist. It is better to have been alive for a decade and have to face our errors than to have been lying immobile blankly gazing at the stars for a millennium. However, there is no virtue in mistakes as such. Our endeavor should be the maximum of activity and progress with a minimum of error and lost motion.

That the names of plants have become so unnecessarily burdened with synonyms may be partly accounted for by the following considerations.

1. We have been so busy looking for differences that we have forgotten that classification is fundamentally based upon resemblances. A distinguished systematist has said that there are two kinds of botanists—"those who see differences and those who do not." I fear that some of the former class have had their discriminating faculties over-stimulated, since species have been founded upon and keyed out upon such valueless characters as one fourth mm. in the length of the stigma and scores of others even less evident.

2. We have thrown down the old concept of a species and we find ourselves in a jungle of illy defined forms out of which we shall never be able to come until we are willing to chop out the water sprouts that grow among and often from the loftier trees. Time tests many species. It is not conclusive, but it is very presumptive evidence against their validity if, as years pass and further collections are made, no other specimens are referred to them. In examining the material in any large herbarium one finds many such hermit sheets.

Let me suggest that there are also two kinds of species, those that exist more or less well defined in nature and those that have only an academic standing. Into which category the different ones will ultimately fall is not in the power of any one mind to settle, for we recognize the truth as expressed by Dr. Gray when he said:

Species . . . are not facts or things, but judgments, and of course fallible judgments; how fallible the working naturalist knows and feels more than any one else.

We often hear of "critical species" and arguments are multiplied to defend their retention in literature. Surely it is true that some of them are valid and stronger even when held on avowedly technical characters than some of the supposedly evident ones that have long been accepted. Nevertheless, one can not help suspecting that the condition of many of these is so "critical" that they can not long survive the untoward conditions that a general upheaval in systematic botany will superinduce.

3. Some of the synonyms are the direct result of mistakes other than that of drawing overfine distinctions. To enumerate the countless causes for these errors is neither desirable nor possible. For each there is always an explanation, not necessarily an excuse. As already stated, error is inseparable from activity. Legislation that would limit publication to those having experience and who are working in a proper environment would be desirable but for two things: (a) It would cut off the future supply of systematists and (b) it is impossible of enforcement. Since prohibition is scarcely possible and surely not desirable, regulation might be attempted. Seriously, why should any one publish a species in a genus in which the known indigenous ones are not all clear to him, unless it be in a genus separable into strongly

marked sections. In that case one might work with some assurance of certainty if all the species in the section were known.

4. It sometimes proves disastrous to assume, as is often done, an inherent improbability that the same species will not be found in districts widely separated geographically. Environmental factors must be reckoned with and these have a trick of repeating themselves in far distant and most unexpected places. Mistakes would be enormously reduced if every one was expected to definitely locate the proposed species in the genus, keying out the species if necessary, or only those of the section should its sectional relationship be apparent.

It is one thing to describe a plant and say (as I and others have done) "apparently not very near any of the hitherto known species." It is quite another to so describe it that it shall be properly contrasted with its nearest ally and its setting in the genus made evident.

It is always hazardous to publish in a large genus unless the examination of its content amounts practically to a tentative monograph. Take a genus at random, *Arnica* for instance, and even a superficial examination of the material in any large herbarium will reveal a number of good species each of which has been characterized by several during the last two decades, apparently because each felt free to assume, for instance, that Colorado and Washington were, for phytographical purposes, on different planets.

5. Another source of error lies in our adherence to different codes or to no codes at all. International law and comity are swept aside. Lawlessness always did mean anarchy in political and social life, and it has brought the same result in taxonomic nomenclature. The moral is not hard to find.

6. Our strength has not all been used in the promotion of constructive work. We spend too much time in criticizing the work of others or defending our own species. Naturally our own children are much better than others, but I doubt if we gain much by rushing to their defense whenever they are attacked. This *species-making* is merely for a day; *species characterization* is for all time. It is true that they may be thrown down to-day and erected to-morrow, but in the course of time the worthy will be established and the worthless will go to synonymy. To love our own is well, but to love them so well as to be willing to juggle the testimony is vicious. Pages and pages are wasted in criticism, recrimination and the imputing of wrong motives. The inexperienced alone are convinced by such speciousness. Those who have learned wisdom know that the attacked party, were he so minded, could put up an equally effective defense. Is it not better, however, to use all available time in productive work, knowing that nothing gets its final rating until established or disestablished by critical monographic work. The one thing we can not afford to be guilty of is insincerity. We simply must deal honestly with nature and justly with the work of our fellows. Personally I would rather my whole brood should perish than to save even the most promising by dissimulation or misrepresentation.

But I must not carry the inquiry as to causes further. There are many questions I had intended to raise, but time will not permit. I must condense into a few paragraphs just a thought as to the influence of the chaotic condition of taxonomy upon the progress of our science as a whole. Morphology, physiology, ecology and economic botany in its scores of applications have all gone forward by leaps and bounds, but it is (dare I say it?) in spite of, not

by the aid of taxonomy. Our unstable nomenclature, involved synonymy, multitudinous, often "half-baked" species have produced the conditions described in this paper. The effect must of necessity be to retard, to discourage, to divert effort.

Now lest I be misunderstood let me say that taxonomic work has not all been misdirected—far from it. Keeness of observation and great powers of discrimination are noteworthy in the work done. It is not so much that what has been done should not have been done, but rather that much greater effort ought to have been made to relate recent work to that which had gone before. Synthesis should have followed so closely upon the analysis of the elements of our flora that duplications would promptly have been discovered and the relation of each element to the other detected and stated.

If we will keep in mind that technical systematic work does not exist primarily for its own sake; that when it ceases to be a means of culture and pleasure to others; that when it becomes burdensome to and unworkable by our fellow botanists in other lines—the chief reasons for its existence have passed, then we shall see more clearly what yet remains to be done. We need to popularize our subject, but not by writing down to those who know little and care less, but by classifying our work so that those who wish to know shall be able to understand. We need more local descriptive floras with well-made keys and illustrations. Our manuals have become too bulky; we cover so much territory that the species are necessarily very numerous. The more species there are in a given genus the more complicated the key and the slighter the differences that separate the species. We ought to have many handbooks and pocket manuals such as the one

Professor and Mrs. H. M. Hall have given us of the Yosemite.

We have had a feeling that our manuals must cover vast sections of the country, many hundreds of thousands of square miles; that they must be complete, accounting for everything ever mentioned. As a result much is found in our volumes that describes things that do not exist, are very rare or have only historical interest for the technically trained. I am pleading for those who want to *know* the plants that relate themselves to their professional work, to their mental life or to their recreations. Please note I said *know* the *plants*, not *know plant names*. No one wishes to know names apart from the plants in which he is interested. Knowing the plant is first, and then a name becomes indispensable.

And why not a name instead of a manufactured phrase palmed off as an English name? In what respect is "purple-stemmed swamp beggar ticks" better than the name? We use geranium, magnolia, forsythia, and scores of others. Why not phlox, mertensia, chrysopsis or practically any other generic name? It is true this only designates the genus, but this is all that many who are intensely interested in the plants care to know, as exemplified by our use of the words clematis, chrysanthemum, lupines and roses. Those who wish to designate the species can do so with more celerity and certainty by saying *Phlox glabrata* than by smooth-leaved sweet william. In my recent "Spring Flora" I proposed this use of the generic name seriously and I wish to assert that I have seen no reason for changing my opinion.

In closing let me express the belief that we are on the eve of a new era. Already the pendulum is swinging back. The dismemberment of genera and the multiplications of species proceed more cautiously. New species will continue to be found even

in this country (hundreds of them). These ought to be and will be published. So long as work is done errors must occur, but the percentage of error, let us hope, will be greatly reduced, while the disturbing effect will be minimized by more and more of constructive work of the compendium type.

AVEN NELSON

UNIVERSITY OF WYOMING,
LARAMIE, WYO.

ON AN EXPERIMENTAL DETERMINATION OF THE EARTH'S ELASTIC PROPERTIES

It is well known that the ocean tides are caused by the differences in the attraction of the sun and moon for the surface and center of the earth. These differential forces are very small compared with the attraction of the earth for bodies on its surface; in round numbers the joint tidal force of the sun and moon on a body at the earth's surface under the most favorable circumstances amounts to only about 1/10,000,000 of the weight of the body. This force would deflect the bob of a plumb line 10 feet long from its normal position only about 1/100,000 of an inch. This deviation corresponds to an angle of only .02", or the angle which the head of a pin would subtend at a distance of 10 miles.

If the earth were a perfectly fluid mass, *i. e.*, if it offered no resistance, either elastic or viscous, to changes of shape, the surface would be tilted by the tidal forces through this same angle, and the new horizontal would be perpendicular to the new vertical. There would therefore be no change of the plumb-line relative to the earth's surface, and we could not detect the so-called "deflection of the vertical."

If the earth were perfectly rigid the plumb line would move back and forth, as the positions of the sun and moon vary, by an amount which can be calculated with an accuracy which is limited only by our knowledge of the masses and relative positions of the sun, earth and moon. As a matter of fact, the earth is partially and not entirely rigid, and therefore the excursions of the plumb line are a certain

fractional part of the full computed value. After this fraction has been found by experiment, it is possible to compute the rigidity of the earth.

In 1879 George and Horace Darwin, at Cambridge, England, attempted to measure the rigidity of the earth. They used a heavy pendulum whose motions were greatly magnified by suspending a small mirror by two fibers very close together, one of which was fastened to the pendulum bob, and the other to a rigid support. However, even with this extremely sensitive apparatus they were unable to separate any movements due to the moon's attraction from the multitude of disturbing displacements caused by changes of temperature, earth tremors, etc.

Of these disturbing elements, a very serious one is the distortion of the land caused by the immense weight of water periodically thrown upon the coasts in the ocean tides. As late as 1898 Sir George Darwin said that he doubted if it would ever be possible to isolate the effects of the tidal forces from the multitudinous disturbances of a more or less accidental character, although he recognized a possibility in the work of Paschwitz and his successor Ehlert, at Strassburg. They had already secured encouraging results by the use of the horizontal pendulum, which is in effect an exceedingly sensitive adaptation of the plumb line.

Since then measurements of this sort have been carried out by von Rebeur, Kortazzi, Hecker, Orloff and others. The experimental results are so obscured by accidental disturbances, however, that their interpretation is difficult, and the results of these various observers differ widely.

In recent years Professor T. C. Chamberlin has been much interested in the possible effect of the earth tides on the ocean tides, and he and Professor F. R. Moulton have for years been anxious to secure some definite data on the plasticity of the earth, on account of its vital bearing on questions of planetary evolution. It was through them that Professor Michelson became interested in the problem of measuring the elastic properties of the earth

and designed the experiments which were conducted last autumn on the grounds of the Yerkes Observatory, at Williams Bay, Wisconsin. These experiments are described in full, with graphs and tables of observations, in the *Journal of Geology* and in the *Astro-physical Journal*, for March, 1914.

Professor Michelson's idea was to substitute a long horizontal water surface for a long pendulum, and measure the changes of level at its ends. There are many advantages in this arrangement. The length may be increased to any desired extent. The water column may be entirely under ground and thus, to a very large extent, freed from temperature disturbances. Earth tremors produce but little if any effect.

The arrangement actually used was as follows. An iron pipe, 500 feet long and 6 inches in diameter, was buried in a trench 6 feet deep along an accurately determined east and west line. At each end there was a pit 10 feet deep and 8 feet square, walled with concrete. The pipe was leveled, certainly to within one half inch, and probably to within one quarter of an inch, and half filled with water. A gauge at each end was connected at the top to the air space in the pipe, and at the bottom to the water. A needle point in each gauge was brought up from below until it nearly touched the surface of the water. The needle point was illuminated through a window in one side of the gauge by a small electric flash light. The under surface of the water formed a very perfect mirror, and the distance between the pointer and its totally reflected image was read, through a second window, with a micrometer microscope. Gauges, pipe and windows were all air-tight, so that fluctuations in barometric height at the ends were without effect. If the gauge at one end was open, the image at the other was not steady, but when both ends were closed, the reflected image was as steady and sharp as the pointer itself. Microscopes were used for which a millimeter at the focus corresponded to about 17 revolutions of the micrometer head. Observations were taken by measuring the distance between the pointer and its image at one end of the pipe,

and subtracting the corresponding difference at the other end. As the water moved, *e. g.*, toward the east end of the pipe, in response to the tidal forces, the difference (E) at the east end increased, since the water was rising higher above the pointer, and the difference (W) at the west end diminished as the water fell there. The difference $E-W$ therefore increased from hour to hour. When the water moved toward the west end of the pipe, the difference (E) decreased and (W) increased, and $E-W$ diminished. The values of $E-W$ plotted as ordinates against the time as abscissas, gave curves which represented the observed tides. Since the water moved down at one end and up at the other, and since the reflected images moved twice as far as the water surfaces, a four-fold magnification was secured. Moreover, since any change in level which might be caused by small changes in temperature or leaking altered the level at both ends alike, the errors caused by such disturbances disappeared in the double difference $E-W$. Changes in level due to the settling of the pipe between the ends were also without effect. If, however, one end settled more than the other, the double difference would increase or decrease, depending on whether the east or west end settled more rapidly, and the whole curve would be given an upward or downward slope. A similar effect would also occur if there were an appreciable change in the slope of the rock strata. But since such changes were not periodic, they would not affect the result seriously.

About eighteen or twenty readings per day, at intervals of from one to three or four hours, were taken during August, and it became evident that the method was capable of yielding very accurate results. A similar line was therefore installed in a N.-S. direction. During October and November readings were taken by the writer on both the N.-S. and E.-W. lines, with the assistance of Mr. Harold Alden, of the Yerkes Observatory staff. Readings were taken once an hour from 6 A.M. to 12 P.M. and once in two hours from 12 P.M. to 6 A.M. About four minutes usually elapsed between readings at one end of a line and the

other. The mean time of the two was taken as the time of the observation. The result was the same as if the two ends had been read simultaneously at the mean time. The observations began at 8 A.M., September 27, and ended at 2 P.M., November 29, 1913.

The curves representing the tides in both the E.-W. and N.-S. pipes were very satisfactory. They showed with great faithfulness tides of the expected form, including the diurnal inequality, and spring and neap tides. The actual change of level at each end at spring tide amounted to about 0.001 inch.

But securing these observations was not all of the problem. It was necessary to know what the tides in the pipes would have been if the earth were absolutely rigid. Computations to determine them were made by Mr. W. L. Hart under the direction of Professor F. R. Moulton. The tidal forces acting on the water in the pipes depend on the positions of the sun and moon relative to the observer. These positions change in a very complicated manner. In the first place, the moon rises in the east and travels westward across the sky because of the earth's rotation. The moon has a motion eastward among the stars, completing a revolution around the earth in a month. Besides this eastward motion, it makes each month an excursion from 28° (at the present time) north of the celestial equator to 28° south of the celestial equator. Its distance from the earth varies by about 10 per cent. during the month, and its eastward motion among the stars is far from being uniform. In addition to all these things the attraction of the sun on the moon causes its motion to be more irregular than it would otherwise be, and it never moves around the earth twice in the same orbit. When all of these complex changes are properly compounded with the almost equally complex ones coming from the sun, the variations in the actual tidal forces are obtained.

Fortunately the Ephemeris gives us the positions and distances of the moon and sun for every hour, thus saving an enormous amount of computation. Even with this aid the work of computing the tides in the pipes

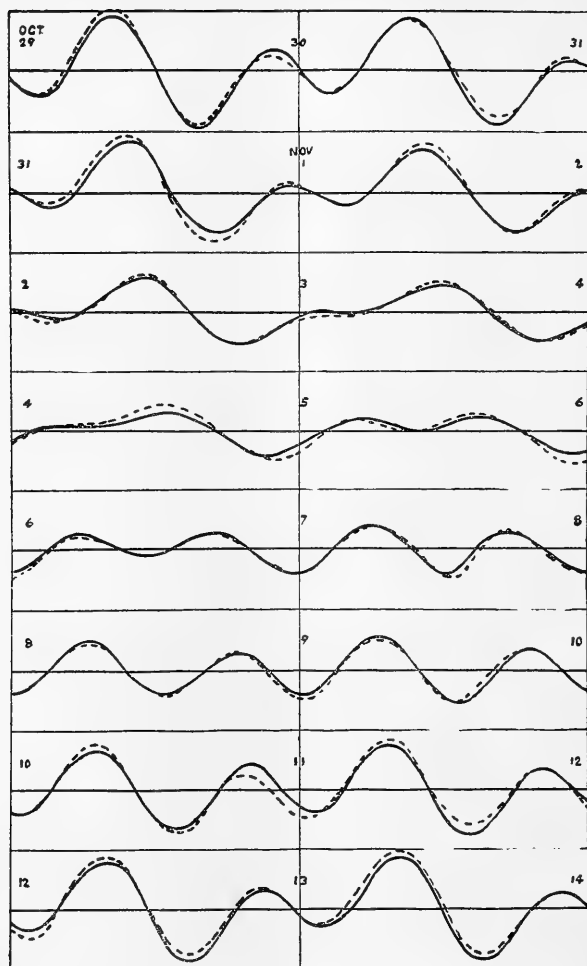

FIG. 1. E.-W. Dotted curve, observed values; full curve, 0.7 of calculated.

was very great. As the experiment progressed and the order of accuracy in the observations was seen to be high, it became necessary to increase the rigor of the computations. It

was found necessary, for example, to take account of the fact that the tidal force of the moon is greater on the side of the earth next to the moon than on the opposite side. This

FIG. 2. E.-W. Mean of all observations, semi-daily lunar tide. Dotted curve, observed values; full curve, 0.7 of calculated.

FIG. 3. N.-S. Mean of all observations, semi-daily lunar tide. Dotted curve, observed values; full curve, 0.5 of calculated.

refinement has not heretofore been necessary in work on the tides, but it introduces differences of as much as 3 per cent. In its final form Professor Moulton's formula, including harmonics of the third order, took account of all factors which affected the result by as

much as 1 per cent., the probable accuracy of the experimental work.

In comparing the observed and computed tides in the E.-W. pipe, Professor Michelson found that if the computed tides were multiplied by the factor $7/10$ they agreed almost

perfectly with the observed ones. But the computed tides for the N.-S. pipe had to be reduced to about one half of the computed values to give the best agreement with the observations. Sample curves for the E.-W. line are given in Fig. 1, and the final mean values of the semi-daily lunar tide for both lines are given in Figs. 2 and 3. The values of the ratios finally adopted were

E.-W.	0.710
N.-S.	0.523

These figures mean that the water tide in the E.-W. pipe was only 71 per cent. of what it would have been if the earth were perfectly rigid, *i. e.*, there is an E.-W. tide in the solid earth which is 290/710 as large as the water tide. In a N.-S. direction there is an earth tide 477/523 as great as the water tide. That is, the earth yields more readily to distorting forces in the N.-S. direction than in the E.-W. direction. Twice each day the surface of the solid earth rises and falls about a foot.

This result is rather surprising, as there appears to be no simple reason why the earth should be more rigid in an E.-W. than in an N.-S. direction. The result was, however, foreshadowed by Schweydar, in discussing the observations of Hecker at Potsdam. A. E. H. Love has suggested that the effect may be due to the distortion caused by the weight of the ocean tides against the edges of the continents.

The times of high tides along the seacoasts with reference to the moon's position are of course very irregular, but if these enormous masses of water were flung against the coasts at the time they were due to rise in obedience to the moon's attraction, there can be little doubt that the effect would be to reduce appreciably the east and west earth tides, and thus to increase the apparent rigidity of the earth in this direction. But the ocean tides are so very complex that there appears to be little prospect of making accurate calculations on this point at present.

Added significance is given to the possibility that the ocean tides are responsible for the difference between the E.-W. and N.-S. rigidity by a consideration of the daily, instead of

the semi-daily, tide. In reducing the observations Professor Michelson found that if he considered the tide of period 25.812 hours, instead of the semi-daily tide, the ratios of observed to computed amplitudes were

E.-W.	0.72
N.-S.	0.66

The agreement here is much better than for the semi-daily tides, but as Professor Michelson has said, if the Love-Schweydar theory is correct, we would have expected a considerable increase in the E.-W. ratio, when the disturbing effect of the ocean tides was eliminated.

Of no less importance than the ratio of the observed to the computed amplitudes is the question of their agreement in phase. It was found that the maxima and minima of the observed and computed tides occurred almost exactly simultaneously. The difference in phase furnishes a measure of the plasticity or viscosity of the earth. If there is no difference in phase between the observed and computed tides, the distortion of the earth does not lag behind the tidal forces; *i. e.*, for any given value of the force the distortion does not tend to increase with the time. If there were a lag in the earth tide, it would throw the observed water tides ahead of the computed ones. This is rendered obvious at once by an appropriate graph. In the reduction of the observations, Professor Michelson found that the N.-S. tides were behind the computed ones, in the mean, by about 24 seconds. This lag could have no physical meaning, and the amount is well within the limits of observational error. In the E.-W. pipe the reduction shows an acceleration of 3.6 minutes. This may be a real acceleration, but the quantity is not far from the limit of accuracy of the observations, and it is too small to be regarded as highly accurate.

The agreement of phase between the observed and computed waves is of great importance for the theories of planetary evolution. Darwin's theory of planetary fission, *i. e.*, the breaking off of the moon from the earth and its subsequent withdrawal to its present distance, is based on the assumption

that tides exist in the solid masses, which are of a viscous and not an elastic character. If tides are raised in a viscous body the protuberances are carried past the line joining the centers of the bodies and the differential pull on the protuberances acts as a brake on the motions of the system. The resulting effect is to slow down the rate of rotation and increase the distance between the two bodies. The tidal theory of the evolution of the moon depends chiefly on the assumption that such tides exist in the earth. The results of this experiment show that the earth-moon system has not undergone the evolution supposed by Darwin unless the interior conditions were formerly vastly different from what they are at present.

Professor Moulton's calculations show that if the ratio of the observed to the calculated tides is taken as 0.70 and the acceleration of phase as the mean of the E.-W. and N.-S., *i. e.*, 1.8 minutes, the mean rigidity of the earth is about 8.6×10^{11} , and the viscosity is 10.9×10^{19} , in C.G.S. units. These are of the order of magnitude of the rigidity and viscosity of steel. These calculations assume that the distortion decreases in geometrical progression as the time increases in arithmetical progression, and that the substance of the earth is homogeneous, a condition which does not, of course, exist. We may say, however, that the earth tides are approximately what they would be if the earth, through and through, had the properties of ordinary steel.

It would be a matter of very great interest to have similar series of observations taken at various places on the earth. Professor Chamberlin is very hopeful that the whole problem of ocean tides, now so intricate and apparently insolvable, may yield to investigations conducted along lines which take account of the joint action of the water tide and body tide. There can be no doubt, as he has pointed out, that the tides in many places are largely influenced by the rocking of the basins. It would be necessary to conduct a number of investigations like the one herein described in different regions to give definite knowledge of the facts as to the amount of the body tide, to-

gether with an ample series of inspections of the basins of the great water bodies. Professor Chamberlin also believes that we should have further investigations of this kind on account of their bearing on vulcanism and seismic disturbances. These phenomena are almost certainly connected with the elastic state and degree of rigidity of the earth-body and of its different parts.

It is Professor Michelson's intention to install an automatic recording device, and to continue the observations at Yerkes Observatory by interference methods. A considerably higher degree of precision is expected.

HENRY G. GALE

THE UNIVERSITY OF CHICAGO

EDUARD SUESS

EDUARD SUESS, dean of modern geology and geologists, passed away on April 26, 1914, in the fullness of his eighty-three years, revered by all students of his chosen earth science and loved by all who came under the influence of his, warm personality.

The son of a German merchant of Jewish extraction, Suess was born in London on August 20, 1831. Here his parents resided until 1834, when they removed to Prague, and eleven years later to Vienna, where the youth was destined to rise to great eminence in the university, in the council of the city, and in the Austrian parliament. Suess was born and lived in an environment that made of him a great linguist, and during a period of his life it is said that he acquired a new language each year. Certain it is that he was at home in many tongues; and more than once, on receiving one of his characteristic letters, has the writer noted the ease with which he expressed his thoughts in English.

While in the Polytechnic School, it became apparent that Suess's natural bent was wholly toward natural history studies, and at nineteen years of age he published his first paper, a short sketch of the geology of Carlsbad and its mineral waters. In 1851 he was appointed as assistant in the geological department of the Royal Natural History Museum at Vienna, where for the next eleven years he devoted

himself to paleontology, and chiefly to brachiopods of the Paleozoic and Mesozoic eras. The comprehensiveness of his mind evinced itself even in these early years, for in 1859 and 1860 appeared a little book of 122 pages, entitled "*Die Wohnsitze der Brachiopoden*," in which he examines the living species, seventy-six in number, and from this draws certain conclusions as to the probable habitats of the fossil forms.

At the age of twenty-four he married the daughter of Dr. Strauss, a distinguished physician in Prague, and, as has been said by Geikie, "entered on a life of great domestic happiness, which largely contributed to the success of a strenuous career wherein science and politics came to be strangely blended."

Geikie says further:

From his youthful days, when he described the Carlsbad springs, he had been interested in underground waters, and among the inquiries which he pursued while attached to the museum was one that embraced the relations of the soil and water supply of Vienna to the life of its inhabitants. In 1862 he published a small volume on this subject, in which he gave a comprehensive account of the economic geology of the district. At that time the city was suffering from an impure water supply and consequent typhoid fever. The luminous essay of the young professor at once attracted attention. He was the same year elected into the town council, that he might give the benefit of his advice in the steps to be taken towards the attainment of better sanitary arrangements. He boldly advocated a scheme for bringing the abundant pure water of the Alps into Vienna by means of an aqueduct 110 kilometers in length. This project, eventually adopted, was brought to a successful termination in 1873. So grateful were his fellow-citizens for the signal service thus conferred on them that they bestowed on him their highest civic distinction by electing him an honorary burgess. By this time he had made his mark in the town council as one of its most useful and able members, so that it was not surprising that he should have been chosen as one of the parliamentary representatives. For more than thirty years he sat in the Austrian parliament as a powerful leader of the Liberal party, only retiring in 1896, when advancing age made the strain of the two-fold life as a politician and man of science too great to be longer borne.

As a geologist and a member of parliament,

it was natural for Suess to be deeply interested in the future supply of the monetary metals, gold and silver. He writes:

Some years after the introduction of the gold standard in Germany, I published, in 1877, a small work, "*Die Zukunft des Goldes*," wherein I tried to show that from geologic indications we must expect in the future a scarcity of gold and an abundance of silver, and that the extension of the gold standard to all civilized states is impossible.

In 1892 he published his "*Die Zukunft des Silbers*," and this work was so well thought of that an English translation was ordered and with the author's consent was published in 1893 by the finance committee of the United States Senate. At that time his predictions were being verified; gold was becoming scarcer, and silver kept on increasing in quantity in spite of its falling price. He says:

Under these circumstances many of my friends and myself were of the opinion that Austria-Hungary, in order to guard herself against all contingencies, ought indeed gradually to acquire a moderate amount of gold, but ought neither to proclaim a gold standard nor establish a definitive ratio between the silver florin and the gold coin.

At the age of twenty-six, Suess was appointed professor extraordinary and in 1867 was promoted to full professorship in the University of Vienna, and for forty-four years he remained a great and enthusiastic teacher, retiring with the title emeritus at the age of seventy. Among his students may be mentioned Neumayr, Mojsisovics, Fuchs, Waagen and Penck.

The greater part of Suess's long life was devoted to working out the evolution of the features of the earth's surface. The problem of mountain-building presented itself to his mind during his many excursions in the eastern Alps, and in 1875 he stated his views thereon in the small volume called "*Die Entstehung der Alpen*," an octavo of 168 pages. Up to this time his publications numbered sixty titles, his studies having ranged over nearly all the branches of geology.

"*Die Entstehung der Alpen*," to quote again from Geikie,

contains the germ of those later contributions to science which have placed him on so conspicuous an eminence among the geologists of the day. It sketches the general principles of mountain-architecture, especially revealed by a study of the Alpine chain. But he did not confine his view to the particular area with which he was himself personally familiar. Already his eye looked out on the wider effects of the unequal contraction of the terrestrial crust, and swept across the European continent eastward into Asia, and westward across the Atlantic into America. . . . To thoughtful students of the science this treatise, in his firm hold of detail combined with singularly vivid powers of generalization, was full of suggestiveness. But the interest and importance of its subject did not obtain general recognition until it was followed ten years afterwards (1885) by the first volume of the great "Antlitz der Erde"—the work which has chiefly given Suess his place among his contemporaries, and by which his name will be handed down to future time. In its striking arrangement of subjects, in its masterly grouping of details which, notwithstanding their almost bewildering multiplicity, are all linked with each other in leading to broad and impressive conclusions, and in the measured cadence of its finer passages, the "Antlitz" may be regarded as a noble philosophical poem in which the story of the continents and the oceans is told by a seer gifted with rare powers of insight into the past.

The writer had the great pleasure of meeting Suess during the Ninth International Geological Congress held at Vienna in August, 1903. Tall and powerful, decisive and yet kind, his great head covered by the familiar soft felt hat, the man left an indelible impress upon my memory during the hour in which we talked of paleogeography, seas and barriers. To me the personal interview was memorable, but the great mental power and vivid imagination of the master mind naturally showed to better advantage at the farewell banquet given by the congress at the Hotel Continental on the evening of August 27. Tietze, presiding as president of the congress, gave the official farewell in French. Following him, and speaking in his own tongue, came Geikie, telling of his first visit to Vienna forty years since, and saying that of those he met at that time nearly all were gone excepting Suess, then a young man of great prominence, since known to all geolo-

gists through his masterly work "Das Antlitz der Erde." This reference to the time when Geikie and Suess—both of whom later became storm-centers in geology—were young, visibly affected the latter. Toward the end of the speaking he arose and with bowed head and in a low voice which increased to greater volume as he went on, he made in German a most eloquent appeal to geologists to rise to ever greater and better work. Unfortunately no one was at hand to take down what he said, and so after the dinner I asked him if he would be so kind as to put his speech in writing. This he did a few days later and a translation of it appeared in the *American Geologist* for January, 1904. In part this is as follows:

Returning to his earth the geologist perceives that the sum total of life's phenomena not only forms a single phenomenon, but that it is also limited by space and time. It occurs to him now that the stone which his hammer strikes is but the nearest lying piece of the planet, that the history of this stone is a fragment of the history of the planet, and that the history of the planet itself is only a very small part of the history of the great, wonderful, ever-changing Kosmos.

His heart then thrills; he feels called as a co-laborer on the most sublime problems in which feeble mortal beings can take part. Then, too, he sees that the fundamental lines of structure coursing over the earth's surface have nothing to do with the political lines separating the nations. The vastness of the problem itself makes the concord of civilized nations natural, and they remain separated only through their emulation, all filled with the idea that mankind in general will most highly esteem that nation which is in the position to offer the most and the best of noble example, of new truth and of ideal worth.

CHARLES SCHUCHERT

YALE UNIVERSITY

SCIENTIFIC NOTES AND NEWS

SURGEON GENERAL W. C. GORGAS has received the degree of doctor of laws from Yale University and from Princeton University.

THE degree of LL.D. was bestowed by the University of California on commencement day on Eugene Woldemar Hilgard, from 1874

to 1906 professor of agriculture and dean of the College of Agriculture; upon George Holmes Howison, Mills professor of intellectual and moral polity in the University of California from 1884 to 1909; and on William Mulholland, the engineer.

At its recent commencement Wesleyan University conferred the degree of doctor of science on Dr. Walter P. Bradley, who has this year retired from the professorship of chemistry which he had held since 1893.

DEAN FRANK D. ADAMS, of McGill University, school of applied science, received the honorary degree Sc.D. at the Tufts College commencement. Incidentally he spoke at the annual dinner of the Association of Harvard Engineers and Dr. and Mrs. Adams were the guests of the geologists of Greater Boston at a dinner at the University Club.

On the occasion of the opening of the new physiological laboratory at the University of Cambridge on June 9, the degree of doctor of science was conferred on Sir William Osler, Sir David Ferrier, Sir Edward Schäfer and Professor E. H. Starling.

The first award of the Chandler gold medal was made to Dr. L. H. Baekeland when the Charles F. Chandler lectureship at Columbia University was inaugurated by an address given by him.

The Royal Society of Arts will confer the Albert medal for the current year on Chevalier Guglielmo Marconi, "for his services in the development and practical application of wireless telegraphy."

The Geological Society of London has elected to foreign membership Dr. F. J. Becke, professor of mineralogy at Vienna; Dr. T. C. Chamberlin, professor of geology in the University of Chicago; Dr. F. J. Loewinson-Lessing, professor of mineralogy and geology at St. Petersburg; Dr. A. P. Pawlow, professor of geology and paleontology at Moscow; Dr. W. B. Scott, professor of geology in Princeton University; Dr. P. Choffat, Geological Survey of Portugal, and Dr. Charles R. Van Hise, president of the University of Wisconsin.

DIRECTOR WILLIAM WALLACE CAMPBELL, of Lick Observatory, has gone to Russia on the Crocker Expedition to observe a total eclipse of the sun. For this purpose Regent William H. Crocker gave \$5,800 to the University of California.

DR. SIMON FLEXNER and Dr. Peyton Rouse, of the Rockefeller Institute for Medical Research, have gone to Spartanburg, S. C., to study the situation in regard to pellagra.

MR. J. S. DILLER, geologist of the United States Geological Survey, has gone to Mount Lassen to prepare a report on the eruptions of the peak.

ON June 23, Dr. Alexander G. Ruthven and Mr. Frederick M. Gaige, of the museum of zoology of the University of Michigan, sailed for British Guiana, where they will carry on zoological field studies. The principal field work will be the study of the local distribution and habits of the amphibians, reptiles and ants, and the gathering of extensive collections of amphibians, reptiles, ants, molluscs and crustaceans. An attempt will also be made to secure specimens in a few groups other than those mentioned, particularly in those needed to fill out the synoptic collections in the museum.

A PARTY from the Peabody Museum of Yale University, under the leadership of Professor R. S. Lull, is to explore the Miocene along the Niobrara River, Nebraska, this summer, in the hope of securing additional fossil vertebrate material to supplement the great Marsh collection at Yale.

DR. ROBERT K. NABOURS, professor of zoology in the Kansas Agricultural College and zoologist of the Kansas State Experiment Station, sailed on May 19 for Rotterdam. He will visit for the college the agricultural experiment stations of Russia, Turkestan and Central Asia, making special study of the work in animal genetics and securing specimens for his experiments. On the return trip he will visit experiment stations in Germany and other European countries.

DR. CHARLES H. ELLWOOD, professor of sociology in the University of Missouri, has been

granted a sabbatical year's leave of absence, and will spend the larger part of his time in England studying social conditions. Dr. L. L. Bernard, professor of sociology in the University of Florida, will have charge of the work in sociology in the University of Missouri during Professor Ellwood's absence.

PROFESSOR L. E. DICKSON, of the University of Chicago, will be visiting professor of mathematics in the University of California from August to December, 1914.

DR. C. H. T. TOWNSEND, director of the entomological station at Lima, Peru, should after July 1 be addressed at the U. S. National Museum.

ON June 4 a number of plant pathologists of the Pacific Coast, meeting at Davis, Cal., formed a Western Branch of the American Phytopathological Society. The following officers were elected: *President*, Ralph E. Smith, Berkeley, Cal.; *Vice-president*, H. S. Jackson, Corvallis, Ore.; *Secretary*, W. T. Horne, Berkeley, Cal.

At the annual meeting of the Medical Research Club of the University of Illinois, Dr. Wm. H. Welker was elected president and Dr. J. J. Moore, secretary, for the next academic year.

THE annual address before the graduating class of the School of Medicine of the University of Alabama, at Mobile, was delivered by Surgeon General William C. Gorgas.

DR. JOHN F. ANDERSON, director of the Hygienic Laboratory, U. S. Public Health Service, delivered the annual address, on June 9, before the Alumni Association of the College of Medicine, Syracuse University. The subject of his address, which was illustrated with lantern slides, was "The United States Public Health Service: its Organization, its Work and its Accomplishments."

A MONUMENT to Captain Scott and the companions who perished with him will be unveiled during the summer at Finse, Norway. The memorial will be nearly 20 feet high, and will bear the names of the explorers, with the inscription, in Norwegian, "The South Pole, January, 1913. Erected by Norwegians."

The funds for the monument have been raised by a newspaper, and donations have been contributed by the Norwegian government, the Geographical Society, and a number of prominent men from all parts of the country.

THE seventh centenary of the birth of Roger Bacon was commemorated at Oxford on June 10 by the unveiling of a statue in the University Museum and by the delivery of a series of addresses. The statue, which is the work of Mr. Herbert Pinker, was unveiled by Sir Archibald Geikie, and was accepted on behalf of the university by the chancellor, Lord Curzon, of Kedleston. It presents Bacon in the habit of a Franciscan friar, holding in his hands an astrolabe with a desk in front of him. It is a full length figure in white marble.

DR. RUPERT NORTON, assistant superintendent of the Johns Hopkins Hospital, died on June 19, of typhoid fever.

DR. JOSEPH REYNOLDS GREEN, F.R.S., known for his important researches in plant physiology, fellow and lecturer of Downing College, Cambridge, and formerly professor to the Pharmaceutical Society of Great Britain, died on June 3.

THE U. S. Civil Service Commission announces an examination for metallurgical engineer, for work in iron and steel, eligibles to fill a vacancy in this position in the Bureau of Mines, Department of the Interior, for service at Pittsburgh, Pa., at a salary ranging from \$3,000 to \$4,500 a year.

THE medical school of the University of Minnesota has adopted the principle of teaching fellowships in the clinical departments, with the end in view of providing well-trained full-time assistants and research workers and at the same time giving a basis for graduate instruction in the various specialties. It is arranged that the fellowships be in three grades; viz., first year, \$500; second year, \$750; third year, \$1,000. To be eligible to a first year fellowship a candidate, as a general rule, must have received his M.D. degree from an acceptable school and have served one year as interne in a good hospital. The fellows ap-

pointed under this system will give their entire time to study, research and such assisting in clinics as they may be prepared for. A course of study will be laid out for each fellow, adapted to prepare him for the specialty chosen by him. This course will include work in the laboratory branches, dispensary service, hospital service and investigation. It is probable that the course (of two or three years?) will lead to a degree properly recognizing the specialty in which the candidate has worked. Arrangements may be made whereby these fellows can spend one year at the Mayo Clinic and count the same toward the advanced degree. In order to inaugurate the system the board of regents of the university has authorized the following teaching fellowships for the next school year: one each in medicine, in surgery, in obstetrics and gynecology and in eye, ear, nose and throat, each of \$500. There is also provision for one \$500 fellowship and one \$1,000 fellowship in mental and nervous diseases, or in lieu of these a \$1,500 instructorship.

THE Geological Survey has completed its preparations for the annual campaign of investigating the mineral resources of Alaska, the field plans for the year having been approved by Secretary Lane. Eleven parties will be put in the field this year, and as in the past special heed will be given to the investigation of the resources of those districts which are tributary to the several routes that have been advocated for the proposed government railways. A party under the leadership of J. W. Bagley and Theodore Chapin will undertake the exploration of the region tributary to Talkeetna River and will connect with the surveys of the Broad Pass region made last year. An exploration of the region lying between Lake Clark on the east and the Iditarod district on the west will be undertaken by R. H. Sargent and Philip S. Smith. A. G. Maddren will investigate the goldplacer districts tributary to the lower Kuskokwim. He will ascend Iditarod River by canoe, portage across the divide to reach the Kuskokwim, and visit the Anniak, Tuluksak and Goodnews Bay placer districts. Stephen R. Capps and

C. E. Giffin will carry geologic and topographic surveys across Skolai Pass into the White River basin and thence to the international boundary. A detailed base map will be made of part of the Juneau district, now the most important gold lode camp in Alaska and promising to become one of the most important on the continent. D. C. Witherspoon will undertake the making of the map, which will be on a scale of three inches to the mile. A survey of the Kotsina copper-bearing area was undertaken in 1912. It is planned that F. H. Moffit and J. B. Mertie now complete this work. B. L. Johnson, with one assistant, will undertake the detailed geologic survey of the Port Valdez gold and copper district. To coordinate and correlate the various geologic surveys in Alaska it is necessary to continue the studies of the general geology and mineral resources. Three geologists will be engaged in this work during 1914. George C. Martin, assisted by R. M. Overbeck, will continue his studies of the Mesozoic stratigraphy. He will visit localities in southeastern Alaska, in the Chitina Valley, and along the Yukon. H. M. Eakin will undertake supplementary investigations of the tin deposits of Alaska. Alfred H. Brooks, the geologist in charge of the Alaska surveys and investigations, expects to leave for Alaska as soon as office work permits. He will study especially the problems of Quaternary geology, including the genesis and occurrence of placer deposits. He will visit the Iditarod and Fairbanks districts and, time permitting, the Nome district. Mr. Brooks will also join the Moffit party in the Kotsina district and the Johnson party in the Valdez district for brief periods of time.

DR. W. P. HERRINGHAM, vice-chancellor of the University of London, and Sir Alfred Pearce Gould, chairman of the Brown Institution Committee, write to the London *Times* with reference to the movement for further university research into the causation of swine fever and other animal diseases; that the work of the Brown Animal Sanatory Institution belonging to the University of London has not

been generally recognized. They say that: "The Brown Institution was founded under the will of Mr. Thomas Brown of Dublin, who died in December, 1852, and left about £20,000 to the University of London for the purpose of 'founding . . . an institution for investigating, and, . . . endeavoring to cure maladies, distempers and injuries, any quadrupeds or birds useful to man may be found subject to.' . . . The institution, at 149 Wandsworth-road, was opened in 1871. Many of its researches have been carried out at the instance and on behalf of government departments, and the diseases investigated have been numerous and diverse in character, including anthrax, actinomycosis, hydrophobia (for the Hydrophobia Commission), vaccinia (for the Local Government Board), tuberculosis, swine fever (for the Board of Agriculture), and sleeping sickness. We may refer particularly to the research on John's disease of cattle by Mr. F. W. Twort, the present superintendent of the institution, and Mr. G. L. Y. Ingram, who succeeded in growing outside the animal body the causative bacillus of the disease. The work had to be curtailed owing to the fact that the institution was unable to provide the funds necessary for the keep of infected animals for experimental purposes. We are thoroughly in agreement with the Berks and Oxon Chamber of Agriculture that such investigations are best carried out in a place like a university. We beg further to point out that in the Brown Institution the University of London has the nucleus of exactly such a research department as is required, and that nothing but adequate funds are needed for its further development."

UNIVERSITY AND EDUCATIONAL NEWS

At the celebration of the centenary of the foundation of the Yale University Medical School, large gifts were announced in addition to the \$500,000 from the General Education Board. These included a provisional gift of \$500,000 for the Anthony N. Brady foundation and \$600,000 from donors not officially named.

By the will of James Campbell, the St. Louis University Medical School will receive

his entire estate after the death of his heirs, who have a life interest in it. The present value of his estate is estimated to be from \$15,000,000 to \$40,000,000.

By the will of Thomas W. Holmes, of Troy, Rensselaer Polytechnic Institute is bequeathed the sum of \$50,000.

By the will of the late Dr. Joseph D. Bryant, professor of surgery in the University and Bellevue Hospital Medical College, a trust fund of \$1,000 is established for the benefit of New York University. The directions regarding it left by Dr. Bryant were as follows: "The income of this fund shall be devoted to instilling in the minds of the senior class the principles of ethics of the American Medical Association." Upon the death or remarriage of his widow, one seventh of Dr. Bryant's residuary estate is to be given in trust to New York University, and one seventh in trust to the New York Academy of Medicine. One contingent bequest of \$10,000 is to be devoted to opposing the efforts of anti-vivisectionists in New York State.

MISS SUSAN MINNS has given \$50,000 to the department of botany of Wellesley College, in memory of Susan M. Hallowell, the former head of the department.

SIR GEORGE KENDRICK has given \$90,000 to the University of Birmingham to endow the chair of physics in memory of the late Professor John Henry Poynting.

THE trustees of Columbia University have appointed Dr. Warfield T. Longcope, to be Bard professor of the practise of medicine to succeed Dr. Theodore C. Janeway, who goes to the Johns Hopkins University. Professor Longcope is also nominated medical director of the Presbyterian Hospital. The department of therapeutics has been merged with that of clinical medicine and Dean Samuel W. Lambert, formerly professor of therapeutics, has been appointed professor of clinical medicine. Dr. Charles C. Lieb has been appointed assistant professor of a new department of

pharmacology and Dr. William Darrach has been appointed assistant professor of surgery.

DR. ROSS A. GORTNER, since 1909 resident investigator in biological chemistry at the station for experimental evolution of the Carnegie Institution of Washington, has been appointed associate professor of soil chemistry in the University of Minnesota.

DR. KARL F. MEYER, whose special field is the tropical diseases, has been promoted to be professor of bacteriology and protozoology in the University of California.

DR. J. HOWARD AGNEW, formerly first assistant in the department of medicine, University of Michigan, has accepted the full time professorship in medicine in the University of Alabama, School of Medicine, at Mobile.

At Dartmouth College, Drs. E. J. Rowe and E. S. Allen have resigned as instructors in mathematics, the latter to accept an instructorship at Brown University. Dr. R. D. Beetle, of Princeton University, and Dr. L. C. Mathewson, of the University of Illinois, have been appointed instructors in mathematics.

D. K. PICKEN, professor of mathematics in Victoria College, University of New Zealand, has been appointed master of Ormond College, Melbourne University.

DISCUSSION AND CORRESPONDENCE

DADOURIAN'S ANALYTICAL MECHANICS

IN the issue of *SCIENCE* of April 3, Dr. Dadourian replies to my criticism of his "Analytical Mechanics." His reply was read with interest. It was hoped that he would clear up several points in this reply that seemed to the reviewer as unsatisfactory. I do not wish to get into a controversy, but it seems to me that his standpoint is untenable. He says in his reply:

It is a fact that I have applied vector addition to forces *without hesitation*, but I have shown as little hesitation in treating velocities, accelerations, torques, linear momenta and angular momenta as vectors. Why did not Professor Rettger accuse me of having assumed the "parallelograms" of these magnitudes? Is the "parallelogram of forces" more of a dynamical law than the parallelogram of torques, for instance? The parallelogram law ap-

plies to any vector and is not at all a characteristic of forces, therefore, it is not a dynamical law. It does not even deserve being called a "law" when applied to a special type of vectors. In its most general form the "parallelogram law" is the principle of the independence of mutually perpendicular directions in space, a purely geometrical principle. . . . After devoting an entire chapter to vector addition and after defining force as a vector, to introduce the "parallelogram of forces" as a new law, as Professor Rettger would have it, could serve only to show that the man who did it could not have a clear conception of the meanings of the terms he was using.

Let us assume that a body, originally in the position O , moves first through a distance, a , in a given direction and then through a distance, b , in another direction. Assume the body finally to be in the position C . The resultant displacement then is $OC = c$. The body would be in the same position, C , if it had moved first through the distance, b , and then through the distance, a , that is, its final position, or its final displacement is independent of the order in which the two displacements take place. They may take place, therefore, simultaneously, and the final or resultant displacement is still equal to c . If then we recognize that the two displacements have no mutual effect on each other, or, what amounts to the same thing, that the displacements are independent of each other, then the resultant displacement may be represented by the diagonal of a parallelogram of which the two displacements are adjacent sides. As soon as this "Principle of Independence" is once recognized, then the "parallelogram law" can be proved to hold also for velocities, accelerations and other conceptions of kinematics. The parallelogram law as applied to these quantities is then equivalent to the "principle of the independence of motions" and as such is a purely "geometric principle." These quantities, displacements, velocities and accelerations are therefore vectors in accordance with the definitions of a vector, and the principles of vector analysis may be applied advantageously.

Vector analysis may be called an algebra that rests on certain (arbitrary) assumptions, and the "parallelogram of vectors" is one of

these fundamental assumptions. To define a quantity as a vector, and then conclude that the parallelogram law holds begs the whole question. The logical way to proceed would be to first *prove* that the quantity is a vector, that is, that the parallelogram law holds and then (advantageously) apply the principles of vector analysis. We can not prove, however, that a *force* is a vector. We must depend upon experience for our justification in assuming a force to be a vector.

We do not know what a force is. To say that "force is an action" explains nothing, and to define it as a vector begs the whole question. Experience and experience alone can justify us in dealing with forces as vectors of a certain kind. In other words, the "parallelogram law of forces" is nothing more than an assumption and is *not* a purely "geometric principle." If we *assume* that a force can be measured by the motion it produces, and if we *assume* that the effect of each force is independent of the effect of the other forces acting, then it follows that the parallelogram law holds also for forces, since we know that this law, as a consequence of the principle of independence, does hold for the motions (accelerations) produced. This argument, however, makes two assumptions. First, it assumes that a force can be measured by the acceleration it produces (in its own line of action), and, secondly, it assumes "the principle of independence" for forces. Now these two assumptions are involved in Newton's Second Law of Motion. In other words, the parallelogram law of forces is a consequence of Newton's Second Law of Motion, and, therefore, in its last analysis is an assumption. If, however, the parallelogram law is once assumed for forces, then it can be proved for moments and other (vector) qualities involving force. It is, therefore, sufficient to *assume* the law to hold for forces.

It is a question whether we have a right to assume the parallelogram law even for velocities and accelerations without proving it, and to assume it for forces is equivalent, as we have seen, to assuming Newton's Second Law of Motion.

In my criticism it was stated:

On page 102 he assumes that a force is proportional to the accelerations produced. This assumes Newton's Second Law.

In reply he says:

This statement is not quite right. The relation between force and acceleration which I have called *force-equation* is derived on page 106 from the fundamental principle which I have postulated. In this derivation I have made use of the definition of kinetic reaction which is stated and illustrated on pages 102 to 105, but this is not equivalent to assuming a new principle.

This is true as far as it goes, but he fails to add that the form of this "force-equation" depends upon the actual value of this "kinetic reaction" which he finds as the result of experiments to be equal to the mass times the acceleration produced, that is,

$$\text{Kinetic reaction} = mf.$$

He seems to me to be making a "distinction without a difference." At least he is making an assumption here that is equivalent to assuming Newton's Second Law of Motion.

CORNELL UNIVERSITY

ACCESSORY CHROMOSOMES OF MAN

IN reply to Professor T. H. Morgan's statement in *SCIENCE*, June 5, 1914, I wish merely to request the reader who may be interested to read my note of May 15¹ and my paper, "Accessory Chromosomes in Man,"² and then Professor Montgomery's paper,³ that he may decide for himself whether Montgomery and I have not agreed in the main regarding the accessory chromosomes of man. This was the only point at issue in my former communication, which was meant not as a "complaint," but as a correction to a misleading inference.

As to the material on which Montgomery and I came to different conclusions regarding a second pairing of the ordinary chromosomes, Professor Morgan is mistaken in stating that

¹ *SCIENCE*.

² *Biol. Bull.*, XIX, 4; September, 1910.

³ *Jour. Acad. Nat. Sci. Phila.*, XV., second series, 1912.

we obtained our results from "the same identical preparations." Montgomery never saw my preparations, nor I his. For a minor part of his work he used some material from the same individual I had worked on, but this material had been standing in alcohol some two years before he obtained it from me, so that it is to be expected that he would not get as clear-cut preparations as from freshly fixed material, to say nothing of the fact that fixation may have been unequal in different bits of the tissue.

Concerning the question of sex chromosomes in fowls, I may say that in my opinion the final word has by no means yet been said. I hope in the near future to contribute some further evidence in the matter.

M. F. GUYER

SCIENTIFIC BOOKS

Chemistry in America. Chapters from the History of the Science in the United States. By EDGAR F. SMITH, Blanchard Professor of Chemistry, University of Pennsylvania. Illustrated. New York and London, D. Appleton and Company. 1914. Pp. xiii + 354. Price \$2.50.

In his preface the author says: "The writer has lectured for several years to his graduate students on the development of chemistry in the United States. A mass of material has been collected, most of which is not only interesting but valuable. Repeated requests have been made for the publication of these facts as a history of chemistry in the United States. To the writer's mind the information in his possession is not sufficiently complete to warrant such an important undertaking. The earliest endeavors of our country's scientists require even more careful and extended research."

The earliest contribution to chemistry from this country appeared September 10, 1767, in the *Transactions of the American Philosophical Society*. The title is "An Analysis of the Chalybeate Waters of Bristol in Pennsylvania." The author is Dr. John de Normandie. Liberal quotations from the article are given which show that the author used the

balance. Then follow quotations from an article by James Madison, who was professor of chemistry and natural philosophy at William and Mary College as early as 1774, and from an article by Dr. Robert McCauslin. The author of the book thereupon remarks: "These communications testify to a spirit of inquiry, at least, on the part of our early devotees to science. They are, further, interesting in that they show the use of the balance as early as 1768 and indicate the steps of analysis."

In 1792 the Chemical Society of Philadelphia was founded by James Woodhouse. The fact is noted that the members of this society favored Lavoisier's doctrine of combustion.

According to Dr. Smith "the arrival of Joseph Priestley in America in 1794, and his frequent presence among the men of science of that day, greatly stimulated scientific studies." But Priestley's thoughts appear to have been on theological subjects fully as much as on scientific in these latter years of his life. He was elected professor of chemistry in the University of Pennsylvania in 1794 but felt obliged to decline the honor. In a letter to Dr. Rush in regard to this he says: "Nothing could have been so pleasing to me as the employment, and I should have been happy in your society, and that of other friends in the capital, and, what I have much at heart, I should have an opportunity of forming an Unitarian congregation in Philadelphia."

Thomas Cooper, professor at Dickinson College and afterwards at the University of Pennsylvania, was the first one to make metallic potassium in this country. He was also the editor of Thomas Thomson's "System of Chemistry." From 1820 to 1834 he was president of the College of South Carolina, "attaining distinction as an extreme advocate of the States' Rights doctrine during the nullification period."

Robert Hare, who was born in Philadelphia in 1781, was without doubt the most influential chemist of his time in America. In 1801, when he was only 20 years old, he communicated to the Chemical Society of Philadelphia a description of the oxy-hydrogen blowpipe which

afterwards came to be known as the compound blowpipe. The communication is entitled "Memoir of the Supply and Application of the Blow-pipe, Containing an Account of the New Method of Supplying the Blow-pipe either with Common Air or Oxygen Gas; and also of the Effects of the Intense Heat Produced by the Combustion of the Hydrogen and Oxygen Gases." Of this Dr. Smith justly remarks, "It is a real landmark in scientific discovery."

Hare later became professor in the University of Pennsylvania which position he held until his resignation in 1847.

Due reference is made to Benjamin Silliman, John P. Norton, Evan Pugh, Robert E. Rogers and Theodore Wormley. James C. Booth is spoken of as probably the first American to study analytical chemistry in Germany. "With an education probably unequalled at that time by any chemist in America, he returned to the United States, and, in 1836, established in Philadelphia a laboratory for instruction in chemical analysis and applied chemistry."

Of T. Sterry Hunt (1826-1892) the author speaks as "an active participant in the up-building of chemistry in America." J. Lawrence Smith (1818-1883) was active about the same time. His paper on a method of analyzing silicates by the use of calcium carbonate and chloride "was a very valuable contribution to analytical methods."

Frederick A. Genth (1820-1893) was a German by birth. He came to this country in 1848. After "conducting a laboratory for commercial analysis and the instruction of special students in chemistry, he became professor of chemistry in the University of Pennsylvania in 1872.

"His earliest contributions were upon geological subjects. Later he devoted much time to mineralogical problems. The chemical research by which he is best known relates to the ammonia cobalt bases (the cobaltamines) developed jointly with Wolcott Gibbs. His original memoir was published in 1851 and contained the first distinct recognition of the existence of perfectly well defined and crystal-

lized salts of the ammonia cobalt bases. The joint monograph of Genth and Gibbs appeared in 1856. This elaborate and extended research has always stood among the finest chemical investigations ever made in this country."

"Wolcott Gibbs (1822-1908) for years held the most commanding position among the chemists of the United States."

"It was Gibbs's peculiar merit, that he, more than any other man, introduced into the United States the German conception of research as a means of chemical instruction."

His investigations covered a wide range of subjects in organic, analytical, organic and physical chemistry. "It was in the great research upon the ammonia cobalt bases, to which reference has already been made, that Gibbs finally found himself."

His most important contribution to analytical chemistry was the electrolytic determination of copper now universally used. "The entire field of electro-analysis was thus thrown open by him." His remarkable series of researches upon the complex inorganic acids, the publication of which began in 1877, continued well into the 'nineties.

Gibbs undoubtedly exerted a powerful influence upon the development of chemistry in this country. His sympathy with young men, his enthusiasm, his absolute fidelity to the highest ideals deeply affected many a young worker and helped to hold him on a true course.

Others whose work is discussed in the book before us are Albert Benjamin Prescott, Samuel W. Johnson (1830-1909), a pioneer in agricultural chemistry, John W. Mallet (1832-1912) of the University of Virginia, M. Carey Lea (1823-1907) and Josiah Parsons Cooke (1827-1894) of Harvard.

The book closes with some account of J. Willard Gibbs (1839-1903) of Yale, whose contributions to physical chemistry "are fundamental in nature and of broad application."

Dr. Smith has wisely refrained from speaking of those who are still alive. In conclusion he says: "It is not the writer's purpose to discuss the investigations which have come from the many working centers of the United

States during recent years, that story awaits another narrator; but, if only a desire, on the part of Americans to learn more concerning the place which American chemists occupy in the world's history of chemistry, is awakened, this compilation of facts will not only have been a pleasure but it will have served a worthy purpose."

The book is to be regarded as a "compilation" and not as a history. All American chemists should be thankful to the author for the pains he has taken to collect this material and for placing it before us. It furnishes the basis for the history of chemistry in America which remains to be written.

It is interesting to note the fact that so many of those who are necessarily mentioned in the book were connected with the University of Pennsylvania. It is, therefore, most appropriate that this work of compilation and comment should have been done by the one who at present holds the two important positions in that university of provost and professor of chemistry.

IRA REMSEN

Das Relativitätsprinzip. By LORENTZ, EINSTEIN and MINKOWSKI. Leipzig: B. G. Teubner. 1913. Pp. 89.

Under the general title *Fortschritte der mathematischen Wissenschaften in Monographien*, Otto Blumenthal is issuing a series of which number 2 is a collection of six papers by eminent advancers of mathematical physics dealing with relativity.

The first paper is a short note by Lorentz of date 1895 in which the hypothesis of shortening in the direction of motion is discussed, practically for the first time, though both he and FitzGerald had for some time been familiar with it. The second is a translation of Lorentz's very famous Electromagnetic phenomena in a system moving with any velocity smaller than that of light, dated 1904. Here not only the hypothesis of shortening, but the Lorentz group, fundamental in relativity theory, is found.

The third article is Einstein's epochal formulation (1905) of the principle of relativity

as a fundamental physical principle independent of any hypothesis of shortening. He goes right at the heart of the matter in that direct way which has been so characteristic of his theories. The next is a short note, not two and one half pages, in which Einstein points out that a consequence of the foregoing work is the proportionality of mass and energy.

Minkowski's *Raum und Zeit* (1908) is the fifth article. Here the simple four-dimensional formulation of mechanics and of the inverse square law of attraction is first clearly exhibited—yet not so clearly that Sommerfeld's explanatory notes are unwelcome. This address of Minkowski's had been reprinted separately, and to the exhaustion of the edition is perhaps due the publication of the present collection.

The final article is from Lorentz's *Alte und Neue Frage der Physik* (1910) and forms an appropriate close to a series which presents concisely and at first hand the steps in the development from the Michelson experiment to the full fledged theory of relativity.

E. B. WILSON

Controlled Natural Selection and Value Marking. By J. C. NOTTRAM. New York, Longmans, Green and Co. 1914. Octavo. Pp. 130.

The author of this book advances a new theory to account for the origin of sexual dimorphism and of polymorphism within animal species. He starts with the assumption that the competition in the struggle for existence is frequently between groups rather than between individuals. Thus, family may compete with family, or pair with pair, rather than individual with individual. Conspicuousness on the part of one member of the family (its least necessary member) it is supposed, may insure persistence of the family by drawing the attacks of enemies to the one and thus diverting them from the more valuable members of the family. Thus male conspicuousness, in sexually dimorphic species, is supposed to be advantageous to the female and young. "Controlled natural selection ac-

counts for both the origin and purpose of secondary sexual characters in the following way. Males are more conspicuous in nature than females: males are less valuable than females. Males and females are associated together during life, and especially during the breeding season when the difference in color is greatest, and when their difference in value is highest; therefore according to the theory, the conspicuous color of the male serves to control natural selection in such a way that the less valuable male will be killed in preference to the more valuable female."

It is assumed that if the male is taken, the female and young will *not* be taken. But the reader might reasonably inquire how the family would be benefited by the loss of its strongest member, and how the survivors would be protected after his demise. Is it to be supposed that the appetites of all enemies will be permanently appeased by a single meal, and that the father having been taken the family will not be further molested?

Not only conspicuousness due to color but also such as may arise from movement, sound or scent is interpreted in this same way. This puts a new meaning on courtship and other means of display and on song, which are all supposed to be protective to the family in which they occur by causing the destruction of those individuals which thus advertise themselves, which result is then supposed to give the others a better chance to survive.

For illustrations in support of his theory the author relies chiefly upon British birds, though reference is frequently made also to insects.

W. E. CASTLE

PUBLICATION OF THE AMERICAN EPHEMERIS AND NAUTICAL ALMANAC FOR 1916

The American Ephemeris and Nautical Almanac for the year 1916, recently issued by the U. S. Naval Observatory, differs materially in construction and arrangement from previous numbers of this publication.

The preparation of this volume marks the inauguration of the scheme of cooperation

adopted by the congress of representatives of the various national Ephemerides held at Paris in 1911. In accordance with this agreement a portion of the material contained in the volume for 1916, including the greater part of the Greenwich Ephemerides of the moon and planets and the apparent places of the stars, has been supplied by the foreign almanac offices, while the office of the American Ephemeris has in turn furnished to all foreign offices the data regarding eclipses, occultations, physical ephemerides of the sun, moon and planets, etc. This system of exchange reduces considerably the amount of duplication of work by different computers, and will, it is believed, prove mutually beneficial to the offices concerned.

Congress has, however, in the law authorizing this exchange, provided that any such arrangement shall be terminable on one year's notice and that the work of the Nautical Almanac Office during the continuance of any such arrangement shall be conducted so that in case of emergency the entire portion of the work intended for the use of navigators may be computed by the force employed by that office, and without any foreign cooperation whatsoever; and that employees whose services in part can be spared on this account may be employed in improving the tables of the planets, moon and stars, to be used in preparing for publication the annual volumes.

A rearrangement of the material contained in the first part of the Ephemeris has been made, with the view of giving it in better and more convenient form for the astronomer. Instead of giving portions of the ephemerides of the sun and moon alternately, month by month, there is now given for the entire year first the ephemeris of the sun complete, then the ephemeris of the moon complete, then the ephemeris of each of the seven major planets.

Other changes worthy of note are the following: Daily ephemerides are given for 35 circumpolar stars instead of 25, and they have been arranged in more convenient form. The apparent right ascensions of stars whose declination is less than 60° are given to 0.0001 , and the apparent declinations of all stars are

given to 0."01. The data relative to eclipses, occultations, physical ephemerides and satellites, are given in Greenwich time instead of Washington time. The style of type adopted permits the publication of much of the material in a more condensed form without loss of legibility.

The preparation of the material for the *American Ephemeris and Nautical Almanac* for 1917, on the same general lines as the volume for 1916, is now well advanced.

J. A. HOOGEWERFF

U. S. NAVAL OBSERVATORY

BOTANICAL NOTES

FOREST TREE DISEASES

A HANDY little field manual for the practical use of foresters has been prepared by E. P. Meinecke, forest pathologist, in the Bureau of Plant Industry of the United States Department of Agriculture, under the title "Forest Tree Diseases Common in California and Nevada." In less than 70 pages the author manages to call the attention of the reader to about twenty-five diseases of various parts of the tree, and to give some general notions as to the nature of disease in plants, and the structure of the fungi which cause most of the tree diseases. Twenty-four half-tone reproductions of photographs help to make it easier for the young forester to identify the particular trouble he may have in hand.

ANOTHER TREE BOOK

APPEALING largely to foresters also, Professor J. H. Schaffner's "Field Manual of Trees," may well be noticed here. For the region covered (Virginia, Kentucky and Missouri northward, and westward "to the limits of the prairie") we do not know of a more useful little book than this. In about 150 pages the author makes it possible for the reader to determine the name and relationship of the native and more commonly cultivated trees of the northeastern United States. It should find a large use in the high schools of the country, and the young forester will find it a most handy book to have in his pocket when he goes into the woods.

A PHARMACEUTICAL BOTANY

IN a little more than one hundred pages Professor H. W. Youngken and F. E. Stewart have condensed the principal morphological and taxonomic portions of botany that they deem should be known by the student before he enters the field of pharmacology. As a hand-book to accompany a course of lectures this little book should prove very helpful, and apparently this was the purpose the authors had in mind when they prepared the text. We imagine that this booklet or one something like it might prove useful in other applications of science, as in agriculture, horticulture, agronomy, medicine, etc.

FLORA OF SOUTHEASTERN WASHINGTON

MORE than a dozen years ago Professors Piper and Beattie, of the State College of Washington published a useful little book under the title "Flora of the Palouse Region," and now they bring out a revision and extension of that work as the "Flora of Southeastern Washington and Adjacent Idaho." In its present form it makes an octavo book of nearly three hundred pages of close, and rather small type. In all 1,139 species are described, and it should be understood that they are *described* and not merely indicated by keys, as is so commonly the case in recent local floras. In fact this is a genuine manual of the systematic botany of a particular region. There is a general key to the families at the beginning of the book, followed by descriptions of the families (with keys to the genera), descriptions of the genera (with keys to the species), and finally good descriptions of the species. The nomenclature is modern and all specific names are decapitalized. It is a most creditable piece of botanical work.

MORE FLORIDA MANUALS

SOME time ago (February 27, 1914) we noticed the botanical activity of Dr. J. K. Small in the preparation of manuals of systematic botany, from the ponderous "Flora of the Southeastern United States," to his "Flora of Miami," "Florida Trees" and "Flora of

Lancaster County" (Penn.) and now we must add two more similar books to his credit. They are the "Flora of the Florida Keys" and the "Shrubs of Florida" both of which appeared within the last few months. The first is a neat little volume of about 160 pages containing descriptions of the seed plants growing naturally on the islands of the Florida reef from Virginia Key to Dry Tortugas, a distance of about 225 miles. As the author remarks, "we find here a tropical flora made up almost wholly of West Indian elements, and closely related to the floras of Bermuda, the Bahamas and Cuba." To a northern botanist it seems strange to find among the grasses no species of *Poa*, nor of *Bromus*; in the sedges no species of *Carex*; in *Brassicaceae* but four species; in *Rosaceae* no species; while the leguminous families aggregate 57 species; *Euphorbiaceae*, 45 species; *Malvaceae*, 17 species, and *Rubiaceae*, 22 species. Of the three families of composites there are but 44 species.

In the other little book (of 140 pp.) the northern botanist will be astonished to find a shrubby grass [*Lasiacis* (*Panicum*) *divaricata*], a buckwheat (*Coccolobis*) forming "evergreen shrubs or trees," the Castor-oil plant (*Ricinus communis*) "a small tree or shrub," a shrubby heliotrope (*Heliotropium*), and a low shrubby *Eupatorium*. Both books will well repay careful examination.

SHORT NOTES

AN interesting paper by Dr. W. B. McDougal on "The Mycorrhizas of Forest Trees" appeared in the first number of the new *American Journal of Forestry* showing that in some cases the relations between the tree and the fungus is symbiotic and sometimes parasitic.

FREDA M. BACHMANN'S paper on "The Origin and Development of the Apothecium in *Collema pulposum*"¹ is a valuable contribution to the theory as to the phylogeny of the Ascomycetes propounded by Dr. E. A. Bessey,² in which he suggested that the first Ascomycetes were lichens. In her paper Miss Bachmann says "in the number and nature of its sperma-

tia and in the manner in which they are borne, *Collema pulposum* forms about the most perfect conceivable connecting link between the aquatic red algae with many non-motile male cells which are, however, set free, and such terrestrial ascomycetes as *Pyronema* and the mildews where the male cells are reduced in number to one or two which remain permanently attached."

A RECENT handful of papers from Professor Doctor Aven Nelson reminds one of the taxonomic activity of the director of the Rocky Mountain Herbarium at Laramie, Wyoming, and serves to show that there is still much to be done in the systematic botany of the central mountains of the country.

DR. O. E. JENNINGS'S "Manual of the Mosses of Western Pennsylvania" (1913) should have been noticed long ago, since it offers to botanists in the central east a descriptive manual of these plants accompanied by fifty-four full-page plates of original drawings. The book includes somewhat more than four hundred pages, and is a credit to the author, and the institution (Carnegie Museum, Pittsburgh) from which it is issued. All told more than 275 species and varieties are described. The treatment is modern, the specific names being decapitalized, and "the rulings of the International Botanical Congress, held in Brussels in 1910, have been followed."

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

SPECIAL ARTICLES

CELL PERMEABILITY FOR ACIDS

SINCE Overton's first extensive and well-known studies and his publication of the lipid theory, interest in the subject of cell permeability has continually increased. Although adherents of the theory have modified and supported it with subsidiary hypotheses the two essentials remain unchanged to-day, namely—(1) that substances which are most soluble in lipoids (fat solvents or fat-like bodies) enter living cells most readily and (2) that they do so because they dissolve in the cell surface which is lipid in nature.

¹ *Archiv. für Zellforschung*, Band X., Heft 4.

² *Mycol. Centralbl.*, Vol. III.

Opinion concerning the lipid theory is divided among those who deny the truth of both first and second statements; those who admit the first but not the second and those who accept the theory in its entirety.

The acids form a group of substances of particular interest in this connection in that they are bodies widely different in chemical composition and physical properties—lipoid solubility, degree of dissociation, surface tension—yet the entrance of each into a living cell may be detected by the same method—color change of a suitable indicator within.

It is impossible to stain living cells with dyes which will serve as indicators for acid, as I had previously done for alkalies,¹ so that recourse must be had to organisms with natural indicators. In plants the blue anthocyan pigments of petals are not sensitive enough to weak acids, such as acetic, to warrant their use. In animals despite the number and the variety in color of pigmented forms, indicators are very rare.

Last winter while a member of the Great

Barrier Reef Expedition of the Carnegie Institution at Washington, I discovered a Holothurian, *Stichopus ananas*, the "prickly fish" of the Beche de Mer industry, whose viscera contain a purple water-soluble pigment turning red-orange in a concentration of acid between $n/1,000$ — $n/500$. The chemical composition of the pigment is unknown, but it appears related to the antedonin described by Moseley² from crinoids and a deep-sea Holothurian. The purple color is contained in sacs or bodies of unknown nature thickly scattered just under the epithelium covering the various viscera, and is especially abundant in the testes and ovaries, although not in the sperm and egg cells themselves. It is of importance to note that the pigment is contained in or surrounded by living cells and death of the tissue results in a rapid diffusion of the purple from the cells as in the case of so many other pigments. Acid diffusing toward the indicator must therefore pass through the layer of living epithelial cells.

series of acids, organic and inorganic, was made and the results are given in the table on p. 948. Pieces of the testis, a branched filamentous organ, were placed in a $n/100$ concentration of acid and the time for color change noted. In addition the partition coefficients of the acids between xylol/water was determined as a measure of the lipid solubility. Only a very few acids will pass to xylol from $n/100$ concentration in water and a few more from $n/10$ concentration. The strength of the acid (after Ostwald), its effect in lowering the surface tension of water (after J. Traube) and its toxicity for cilia (studies of my own carried out in Torres Strait) are also included in the table. The acids are arranged in order of efficiency in each case. Those with nearly the same effect or property are tabulated in groups and in an order to correspond as nearly as possible with the penetration series. An asterisk marks the acids considerably out of place in each series as compared with the penetration series.

With the exception of benzoic and salicylic all the acids encounter a resistance—small for some, greater for others—at the cell surface. If the tissue has previously been killed this resistance is abolished and the cells become readily permeable for all acids. The specific permeability of the tissue for each acid is therefore dependent on the living cells.

It will be noted that there is no exact quantitative agreement between any two of the series. The best agreement is between penetration rate and toxicity; the worst between penetration rate and degree of dissociation. One may conclude that those acids are most toxic which are able to penetrate the cell most rapidly, a conclusion supported by my results with alkalis. In neither case is there a relation between toxicity and dissociation.

As regards the lipid theory my results can not be said to wholly support it; neither do they wholly contradict it. The same statement applies to Traube's Haftdruck theory. There is a general relation between the power to lower the surface tension of water (capillary activity) and rate of penetration, but it is not exact. With acids as with dyes and so many

other substances, Overton's theory applies in the majority of cases, but not in all. In my opinion this can only mean that the power of penetration of an acid depends on several variable factors. One of these is lipid solubility or capillary activity, for the two run more or less parallel, and a second is the strength or affinity of the acid for certain protein substances of the cell surface. This would explain the rather rapid penetration of strong acids little soluble or insoluble in lipids.

April 23, 1914

A DESTRUCTIVE STRAWBERRY DISEASE

MANY of the long-distance strawberry shipments of this season have suffered serious injury culminating in a condition designated by the consignees as "molds" or "leaks."

In case of mold the berries, one or more per box, often quite the whole contents of the box, are more or less densely covered with a hairy mold.

The term "leak" designates a condition in which a liquid issues copiously from the bottom of the box. "Leaks" are accompanied by a soggy condition of the berries which mat down to occupy only one third or one fifth of their original volume.

The loss occasioned by these conditions is very large and will in all probability reach well into the millions this season. The berries now so affected originate in Louisiana and Mississippi. Data are not available concerning conditions in other states. The conditions mentioned have not occurred in previous years to sufficient extent to attract the marked attention of the buyers or inspectors though it is hardly to be supposed that they have been entirely absent.

The writer on April 30, acting for the Illinois Central Railroad, visited the berry region of Louisiana to ascertain the condition, the cause, and to render any assistance possible.

A preliminary examination at Hammond, La., May 1, of berries which had been in refrigerators over night, which had been picked

about eighteen hours, showed that these berries on an average exhibited two or three per box with very small rotten spots, perhaps 2 to 3 mm. in diameter though only rarely, even under the lens, was any mold apparent.

Visits to the fields showed many berries, green as well as ripe, rotting and molding while still on the vines.

While several types of fungi were present the one which was most characteristic was a *Botrytis*, probably *Botrytis cinerea*.

In the disease history, typically, the rotten spot appears, attains a size of several millimeters. Then a slight surface mold visible under the lens comes over the spot. Later the center of this area becomes coated with the typical *Botrytis* conidia, the whole berry becoming rapidly involved.

In late stages the picture may become complicated by invasion of other fungi, particularly by *Rhizopus nigricans*.

The sorters on the berry farms throw out most of the infected berries and these may be seen, bushels of them, near the sorting benches. Such discarded berries when several days old were almost always covered with *Botrytis* spores and the refuse heap reminded one of an immense culture dish of this fungus, though invariably contaminated by *Rhizopus*.

To ascertain whether apparently sound berries were really infected culture chambers were improvised of jelly jars with the aid of absorbent cotton.

The following tests were made in such dishes:

1. A large number of berries showing incipient decay but with no mold visible under the lens, were cultured. In twenty-four hours every berry showed profuse mold in nearly all cases of the *Botrytis* type; in a few cases other and various types.

2. A large number of apparently healthy berries, fully ripe, but carefully selected were cultured. These at twenty-four and at forty-eight hours showed no mold.

3. A large number of ripe healthy berries were severely jammed, bruised and crushed then cultured. They showed no mold in twenty-four hours.

4. A large number of berries showing various imperfections, sun scald, blister, insect injury, imperfect fertilization but no rotten spots were cultured. No mold appeared.

5. Sound berries were placed half covered with water. No mold appeared in twenty-four hours.

All of the above tests were made at room temperature.

From the practically universal presence of the *Botrytis* on young infected areas and its predominance on the refuse heaps I believe that this fungus is the primary cause of the molding, that the *Botrytis* initiates the decay, opening the way to such other saprophytes as may be present; of such saprophytes, *Rhizopus* is by far the most prominent and most abundant.

Laboratory tests which I have since made show that a berry inoculated with *Rhizopus* will rot rapidly with the escape of a large amount of liquid. It therefore seems probable that the "leaks" are due largely if not entirely to *Rhizopus* invasion.

Both the *Botrytis* and *Rhizopus* have been separated in pure culture in my laboratory and further study of these as well as of the other berry fungi will be made.

In the way of prevention extremely rigid sorting should be emphasized and it would also be well to prevent the refuse heaps from becoming culture beds of the fungus. This can perhaps best be accomplished by liberal use of lime.

F. L. STEVENS

URBANA, ILLINOIS,
May 8, 1914

THE AMERICAN CHEMICAL SOCIETY

THE forty-ninth general meeting of the American Chemical Society was held at Cincinnati, Ohio, Monday, April 6, to Friday, April 10. The meeting opened with a council meeting on the evening of April 6. Tuesday morning the general meeting of the society was held in the auditorium of the University of Cincinnati and was addressed by the Hon. Frederick S. Spiegel, mayor of Cincinnati, and by President Charles W. Dabney, of the University of Cincinnati, both welcoming the society to the city. President T. W. Richards, of

the American Chemical Society, fittingly responded. The society then held a general meeting, at which the following papers were presented:

"The Chemical Problems of an Active Volcano" (illustrated), by Arthur L. Day.

"The Chemical Fitness of the World for Life," by L. J. Henderson.

"Flame Reactions," by W. D. Bancroft.

"Chemical Reactions at Low Pressures," by Irving Langmuir.

At one o'clock the society adjourned for an excursion to the Filtration Plant of the Cincinnati Water Works, optional excursions being available to the following plants:

Andrews Steel Co., Wiedemann Brewing Co., Old "76" Distilling Co., Frank Tea and Spice Co., Heekin Spice Co., Icy-Hot Bottle Co., Cincinnati's New City Hospital preceded by car ride through suburbs, the Dolly Varden Chocolate Co., W. T. Wagners' Sons Mineral Waters.

In the evening, a complimentary dinner was given to the ladies attending the meeting, followed by a theater party. At eight o'clock, P.M., a complimentary smoker was held at the Hotel Sinton, with 550 members and guests present. Mementos were given to all those attending, and the smoker will long be remembered, especially for the interesting and witty entertainment provided by the local members, and by talent especially engaged for the occasion.

Divisional meetings were held on Wednesday morning and all day Thursday at the University of Cincinnati, at which 181 papers were presented, a special symposium on the teaching of organic chemistry being also held by that division.

Complimentary lunches were furnished on Wednesday and Thursday. On Wednesday afternoon the members were taken through the works of the Globe Soap Company and Proctor and Gamble, with the following optional excursions also offered, W. S. Merrell Chemical Co., Lloyd Library and Museum, Fleischmann Distilling Co., American Diamalt Co., Eagle White Lead Co., National Lead Co., Lunkenheimer Co. Brass Goods, the Zoological Gardens.

On Wednesday evening a symphony concert was given complimentary to the members of the society, and the immense Emery auditorium was filled to hear a concert, under the direction of Ernst Kuhnwald, which has had few superiors in the history of American music.

On Thursday evening, a banquet was enjoyed

by the members at the Hotel Sinton, with some 300 present. The banquet was unusual in that especially fine music was furnished by soloists. A decoration particularly worthy of note was an immense American Chemical Society pin in blue and gold flowers.

On Friday a special train complimentary to the members of the society took them and their guests to Dayton to visit the works of the National Cash Register Company, where lunch was served to all of those attending, after which the train proceeded to the works of the American Rolling Mills, at Middletown, and from there to Cincinnati. This day's excursion was particularly enjoyed and the works visited were among the most interesting ever opened to the members of the society.

The meeting closed with the arrival of the members in Cincinnati, and will always be remembered by those present. The members and officers of the Cincinnati section made every effort to insure the comfort and entertainment of their guests, and their hearty good will will never be forgotten by the recipients of their hospitality.

Meetings of all of the divisions of the society, as well as the India Rubber Section and the Water, Sanitation and Sewage Section were held. Details will appear in the published program, as above stated.

The meeting was the largest spring meeting ever held in the history of the society, 658 members and guests being present.

The following are abstracts of the papers presented before the various divisions so far as they could be procured:

DIVISION OF AGRICULTURAL AND FOOD CHEMISTRY

Floyd W. Robinson, chairman

Glen F. Mason, secretary

Address. FLOYD W. ROBINSON, chairman.

Standards of Food and Drug Chemists: EDWARD GUDEMAN.

The Determination of Mixed Carbohydrates in Infant Foods: T. M. RECTOR AND E. B. WETTINGEL.

In preparations containing mixtures of sucrose, maltose, lactose and dextrine, the sucrose is determined by loss of rotation after inversion with invertase. The dextrine is determined by loss of polarization after precipitation with lead acetate and ammonia. The combined polarization of the sucrose and dextrine is subtracted from the total polarization, giving the polarization of the mal-

tose and lactose. A copper reduction is then run on an aliquot of the solution and the amount of copper reduced by 1 gm. of the sample is calculated. From this value and the combined polarization of the maltose and lactose the percentages of these sugars are calculated by a formula.

The analyses of some commercial infant foods by this method are given.

The Determination of Tannin in Tea: H. C. FULLER.

The powdered tea is first extracted with petroleum ether, which is discarded, and then percolated with 50 per cent. alcohol. The alcoholic solution is precipitated with an excess of lead acetate solution and the whole made up to a definite volume. An aliquot of this is then taken and the excess of lead precipitated with hydrogen in the presence of sodium hydroxide, the lead sulphide being filtered into a tared Gooch, washed and dried over sulphuric acid. A blank is run at the same time and the difference in lead figures is a measure of the lead taken up by the tannin.

A Rapid Method for the Determination of Sodium Chloride in Butter and its Substitutes: T. M. RECTOR.

The salt is determined by titration with silver nitrate with chromate indicator, in a water solution of a weighed sample of butter in the presence of the butter fat. Some results are given to show that the butter fat does not interfere with the accuracy of the method.

A Rapid Method for the Determination of Unsaponifiable Matter in Fats and Oils: T. M. RECTOR.

The sample is saponified in the usual manner and the alcoholic soap solution diluted to an alcohol content of 55 per cent. The solution is then extracted with light petroleum spirit, the solvent evaporated, and the residue dried in vacuo and weighed.

Freedom from emulsification is claimed for this method.

The Determination of Caffein in Coffee and Tea: H. C. FULLER.

The sample is ground so that it will pass through a 60-mesh sieve and a weighed amount boiled with dilute hydrochloric acid; the decoction filtered and the extracting process repeated three times with boiling water. From the filtrate the caffein is removed with chloroform, after rendering alkaline with ammonia, and after recovering the solvent the crude caffein is dissolved in acid and precipitated with iodide, and finally

recovered from the iodide precipitate by treatment with sulphite and shaking out with chloroform.

The Official Method for Determining Crude-fiber as Applied to Cottonseed Meal: CHAS. K. FRANCIS.

The Arsenates of Lead: H. V. TARTAR AND R. H. ROBINSON.

Methods have been developed for the preparation of pure lead hydrogen arsenate and lead pyroarsenate. All attempts to prepare lead orthoarsenate have failed. A new basic lead arsenate has been prepared. The authors believe that lead orthoarsenate is not a constituent of the ordinary commercial salts used as insecticides. The substance present which has been thought to be the orthoarsenate is in reality the basic lead arsenate mentioned above. The specific gravity of pure lead hydrogen arsenate is 5.786 and of the basic arsenate is 7.10. Analytical methods have been worked out for the quantitative estimation of lead hydrogen arsenate in the presence of the basic arsenate. This paper will soon be presented in full for publication in the *Journal of the American Chemical Society*.

The Changes Produced by the Wrapping of Bread: H. E. BISHOP.

The Determination of Lecithin-phosphorus in Macaroni and Farinaceous Articles: H. C. FULLER.

The macaroni is thoroughly softened with hot water, the mass treated with a large excess of alcohol, the liquid filtered and the solid substance treated with further portions of alcohol; the combined alcoholic solutions are evaporated and the residue extracted with ether, which dissolves the lecithin. Phosphoric acid is determined in the latter by ignition of calcium acetate and finishing in the usual way with ammonium molybdate and magnesium mixture.

Lobster Oil: H. S. BAILEY AND L. B. BURNETT.

In the cooking of lobsters preparatory to canning there is always a layer of oil collected upon the top of the kettles. For a number of years it has been the custom of the packers to skim off this oil and sell it to the dealers in fish oil who doubtless mixed it in with their low-grade products. Through the kindness of Dr. W. D. Bigelow we were able last year to obtain a sample of this lobster oil. It is a bright orange red in color and has a characteristic fishy odor and taste. A search of the literature failed to reveal any mention of this oil, although König¹ states that the

¹ *Chem. Nahr-u-Genussm.*, Vol. II., p. 493.

fresh German lobster contains about 1.84 per cent. of oil.

An analysis of this particular sample gave the following results:

Specific gravity, 25°/25°	0.9255
Refractive index, 25°	1.4765
Iodine number	145
Saponification number	175
Soluble acids (as butyric)	0.65%
Saturated (solid) acids	10.5%
Unsaturated (liquid) acids	80%
Insoluble acids	88%
Acetyl value	16.9
Iodine number of unsaturated acids	160
Iodine number of saturated acids	1.5
Melting point (capillary tube) of solid acids	51.6° C.
Molecular wt. of unsaturated acids	315
Saponification number of acetylated fat ..	184

Tomato-Seed Oil: H. S. BAILEY AND L. B. BURNETT.

The rapidly increasing production of tomato pulp and catsup in the United States, and the fact that oil is already being made on a commercial scale from the waste tomato seeds in Italy, make an investigation of the composition of this oil very desirable. Last season a few pounds of tomato seeds were obtained, and pressed in an expeller of the continuous action type. The oil thus obtained refined and bleached easily and was apparently a satisfactory food oil.

The Digestibility of Corn Consumed by Swine: S. C. GUERNSEY.

Digestion trials to compare the digestibility of maize in the natural state, with that of the shelled and ground grain, the latter two forms being fed both dry and soaked, were conducted in 1909 with 10 heavy-weight swine, weighing about 200 pounds, in 1910 with the same number of light-weight animals weighing about 70 pounds, and in 1911 with 10 light-weight and ten heavy-weight hogs. Each year the different forms of maize were fed through four ten-day periods to the swine, which were kept in cages, five animals being fed at a time, each receiving one form of corn through a ten-day period. The apparent digestibility was determined by weighing and analyzing the feed and corresponding feces, the latter being collected in rubber bags attached to the animals by a harness. A charcoal marker was fed at the beginning and end of each period for identification of the corresponding feces. The light-weight swine digested whole-grain on cob, and shelled

grain more thoroughly than did the heavy-weights, while the latter utilized the soaked ground grain to better advantage than did the former. With the light swine, the whole grain on cob has the highest digestion coefficient, then dry shelled, dry ground, soaked shelled and soaked ground grain, while with the heavy-weights the soaked ground grain has the highest digestibility, then dry ground, dry shelled, ear and soaked shelled corn. A remarkable correlation between digestibility and time required for digestion was found in the series of experiments conducted in 1909-10, brought to notice by observations on the interval between the feeding of bone-black and its appearance in the feces. In a general way, the higher the coefficient of digestion, the longer the time required for the feces to pass through the alimentary canal, and *vice versa*, which holds true with both classes of swine as a whole or as separate classes.

Chemical Changes Occurring During the Period of Silage Formation: RAY E. NEIDIG.

The investigation included studies of the principal chemical changes which occurred in three silos built of different materials. The period covered was the first three weeks after filling the silos. The rate of increase or decrease of the following substances was determined daily: volatile acids, non-volatile acids, soluble carbohydrates and alcohol. Daily analyses were made of the gases of the silos and temperatures were taken by means of electric thermometers buried in different parts of the silos. The results show that sucrose is hydrolyzed to invert sugar in the early stages of fermentation and then a very gradual loss in carbohydrates is noted. The soluble carbohydrates do not disappear entirely, however, and those remaining were identified as invert sugar. Along with the gradual diminishing of the carbohydrates there is a uniform rise in acidity; both volatile and non-volatile acids are formed, the latter predominating. The volatile acid consists mainly of acetic acid together with some propionic acid; the non-volatile acid is the inactive or racemic variety of lactic acid. Alcohol was found in small quantities in all silos in slightly varying amounts. The gas analysis showed a rapid production of carbon-dioxide after filling the silos, reaching the maximum during the first few days and then gradually decreasing. Oxygen, on the other hand, was found only in traces after the first three days. The temperatures were quite uniform in all silos, the maximum temperature observed being 32.8° Centigrade.

Preliminary Notes on the Curing of Cucumber Pickles: H. N. RILEY.

The activities manifest in a curing tank of cucumber pickles seem all to depend upon the growth of certain bacteria, known as "lactic-acid bacteria." These seem to govern the rate of fermentation, or giving off of gas, and the production of acid. The rate of fermentation mechanically governs the rate of absorption of salt, which is also influenced, to some extent, by the size of the pickle. The growth of mold and yeast seems destructive as they destroy the acid which is the principal keeping factor in the brine.

A Rapid Graphic Method for Calculating Rations and Diets: D. L. RANDALL.

The different common foods were classified according to the weight of protein in a hundred calorie portion and were arranged graphically on cards so that the distance taken up by any quantity of a food is the same as that which represents the protein as plotted to a definite scale. By suitable manipulation of these cards one can determine the quantity of different foods in combination necessary to get a definite amount of protein and energy and can determine the composition of any mixture of foods, all this being done with no other calculation than the addition of simple whole numbers usually less than ten.

The Hydrolysis, under Pressure, of Sugar Solutions: W. S. HUBBARD AND W. L. MITCHELL.

Notes on the Determination of Total Sulfur: PHILIP L. BLUMENTHAL.

Barium in Various Plants: NICHOLAS KNIGHT AND LESTER W. RUSK.

The leaves and stems of thirteen different plants and common trees have been examined and barium has been found in all of them. Twenty-five grams of the leaf or stem have been taken for each determination. The investigation will be extended to include plants from widely different localities.

The Non-uniformity of Drying Oven Temperatures: LORIN H. BAILEY.

Tests on eight different types of drying ovens, including those heated by gas, electricity, hot water and steam, showed that only those ovens which are surrounded by boiling water and steam, or by steam alone, maintain uniform temperatures. Other ovens show maximum variations of from 15° C. to 24° C. throughout the drying chambers, and a range from 2° to 17° C. from the temperature indicated by thermometer inserted through the top of oven and ordinarily taken as the tem-

perature at which the drying is done. It is the type rather than the price that makes a good oven.

The Analysis of Alkali Soils: C. N. CATLIN.

The determination of "alkali," in soil, is one of the most important analyses the agricultural chemist in semi-arid countries is called upon to make, but there are no standard methods for the determination. The author has collected and made a comparative study of many of the methods now in use. The results in several cases were not even comparable, the percentage of water soluble solids by some methods amounting to several times that found by others. Chlorides corresponded approximately. The chief source of difference lies in the completeness of solution of sodium carbonate and of calcium sulphate, neither of which is dissolved easily and completely from the soil. The highest results were obtained by the method in use at the Arizona Agricultural Experiment Station. This consists in digesting 50 grams of soil with 800 to 100 c.c. of water for ten hours on the boiling bath, whereby a constant and complete extraction of water-soluble salts is secured. Aside from the difference due to completeness of extraction, large discrepancies were found in determining sodium carbonate.

Dates: Comparative Cost of, in Akron, Ohio: CHAS. P. FOX.

The Composition of Gooseberries, with Special Reference to their Pectin Content: E. H. S. BAILEY.

Some preliminary analyses have been made upon a variety of wild spiny gooseberries that grow abundantly through northern latitudes. The interior of the half-ripened berry; the condition best suited to jelly making, consists of a firm, hard, glistening mass, with but few seeds. In order to obtain the juice it is necessary to boil the crushed berries repeatedly with water. On a large scale the berries yield 9.88 per cent. of insoluble material, including skins, seeds and short stems.

A preliminary analysis of the berries gives:

	Per Cent.
Dry solids	19.42
Ash87
Ash, soluble in water87
Ash, insoluble in water33
Proteins	1.37
Acid (as acetic)	1.27

Since pectins are precipitated by mineral salts, the question is raised to what extent the use of

hard water in the making of jellies reduces the pectin contact. Experiments in this line are being conducted. A bibliography of recent work is appended.

A Rapid Method for Commercial Analysis for Marls and Limestones: O. B. WINTER.

The commercial value of marls and limestones used for agricultural purposes depends largely upon their content of calcium and magnesium in the form of carbonates. Two methods are given for estimating lime—one, precipitating the calcium oxalate in the presence of oxalic acid, and the other, in the presence of hydrochloric acid. The carbon dioxide is determined by treating the sample with a small volume of hydrochloric acid and measuring the gas evolved. Results show that this method for carbon dioxide compares favorably with several other methods when certain precautions are used.

The magnesium is determined by calculating the amount necessary to combine with the carbon dioxide not taken up by the lime.

A Method for the Estimation of Calcium, Strontium and Magnesium in the Presence of Phosphoric Acid and Iron: O. B. WINTER.

Calcium and strontium are precipitated as the oxalates in a dilute hydrochloric acid solution. The oxalates are burned to the oxides, weighed and then nitrated and the nitrates weighed. The amounts of each (calcium and strontium) are determined as follows: (1) By separating the nitrates with absolute alcohol and ether. (2) By calculation from the amounts of oxides and nitrates. The magnesium is determined as magnesium pyrophosphate in the filtrate from the oxalates, by removing the ammonium salts and silica, and keeping the iron in solution by means of sodium acetate.

The Chemistry of the Decomposition of Peat and Muck: C. S. ROBINSON.

Some Pot Experiments with Mixtures with Peat and Manure in Connection with Various Fertilizers: C. S. ROBINSON.

BIOLOGICAL CHEMISTRY DIVISION

Carl L. Alsberg, chairman

I. K. Phelps, secretary

Coagulation of Albumen by Electrolytes: WILDER D. BANCROFT.

Colloidal Swelling and Hydrogen Ion Concentration: L. J. HENDERSON, W. W. PALMER AND L. H. NEWBURGH.

The Functions of Ammonium and Phosphoric Acid in the Regulatory Excretion of Acid: L. J. HENDERSON AND W. W. PALMER.

Partition of the Nitrogen of Plant, Yeast and Meat Extracts: F. C. COOK.

There is great variation in the precipitating power of the different reagents compared. Phosphotungstic acid precipitated the highest, tannin salt reagent the next highest and acid-alcohol the lowest percentage of the nitrogen of the seven plant, five meat and one yeast extracts examined. The formol titrated method gave lower results for amino nitrogen than the Van Slyke method. All of the methods showed a larger percentage of the nitrogen present in a more completely hydrolyzed state in the plant than in the other extracts. No kreatinin, and very little purin nitrogen was found in the plant extracts. The yeast extract was high in purin nitrogen, but contained no kreatin or kreatinin. The nitrogen of the plant extracts was found in the filtrate from the acid-alcohol reagent. Twenty-five per cent. of the nitrogen of the other extracts was precipitated by this reagent. The plant extracts showed more ammonia by the Folin method than the other extracts.

Comparison of the Various Methods for the Quantitative Determination of Sugar in Blood: MAX KAHN. (By title.)

Clinical Studies of the Russo Test: MAX KAHN. (By title.)

Urinary Catalase in Health and Disease: MAX KAHN AND C. J. BRIM. (By title.)

A Standard in the Determination of Ammonia by Nesslerizing with the Duboscq Calorimeter: A. R. ROSE AND KATHERINE R. COLEMAN. (By title.)

Nephelometry in the Study of Nucleases: P. A. KOBER.

A Soluble Polysaccharide in Lower Fungi: A. W. DOX.

The Chemical Dynamics of Living Protoplasm: W. J. V. OSTERHOUT.

The Physiological Water Requirement and the Growth of Plants in Glycocoll Solutions: ALFRED DACHNOWSKI AND A. GORMLEY.

Though it is not known precisely to what extent amino acids occur in peat soils, the question of the ability of plants to utilize directly nitrogenous compounds in the soil other than nitrates and ammonia is of considerable importance. The data presented show that the absorption of glycocoll is not connected with the transpirational water loss, but with the efficiency of the nutritive metabolism characteristic of the plant, and with the amount of water retained within the plant and involved in metabolism. Changes in body weight, if taken as the measure of growth, may be pronouncedly altered by the quantity of the metabolically retained water as well as by the deposition or removal of reserve materials in the tissues. The failure to promote continuous growth may be due to the inefficiency of glycocoll to supply material for tissue construction. This and the lack of available water enforce compensating processes in the plant. The apparently inevitable conclusion is entertained that the problem of the water requirement of plants and the criteria for the wilting coefficient, in particular the relation between the water content of the plant and that of the soil at the time of wilting, need to be reinvestigated more quantitatively than has heretofore been attempted. The retention of water, not transpiration, is the physiological function correlated with and indispensable to growth in general, and to survival and greater areal distribution of plants entering physically or physiologically arid habits. (To appear in *Amer. Jour. of Botany*, Vol. I., April, 1914.)

The Estimation of Amino Acids as Such in the Soil: R. S. POTTER AND R. S. SNYDER.

Methods Adapted for the Determination of Decomposition in Eggs and in other Protein Products: H. W. HOUGHTON AND F. C. WEBER.

The methods that were found most applicable for the determination of decomposition are the Folin titration and Nesslerization methods for free ammonia, Klein's modification of Van Slyke's method for amino nitrogen and Folin-Wentworth method for acidity of fat. Calculating the results on liquid eggs to a moisture-fat free basis, the following amounts of ammonia nitrogen in milligrams per 100 grams of material were obtained: By the Folin titration method, seconds gave, 11.4, spots, 14.1, light rots, 17.3, rots, 26.2, black rots, 169.6; by the Folin-nesslerization method, seconds gave, 12.4, spots, 20.0, light rots, 21.5, rots, 29.9, black rots, 148.6. The amino

nitrogen determination is of service in detecting liquid and dried blood rings, spots and light rots. The increase in the acidity of the fat detects spots and worse grades of eggs. The ammonia methods applied to herring give results indicating decomposition of the fish after standing 24 hours at about 70° F. Applied to clams, an appreciable increase in the ammonia is shown after keeping two days at a temperature of 60° F. to 65° F.

Factors Influencing the Quality of American Sardines: F. C. WEBER AND H. W. HOUGHTON.

This paper embodies some of the results of the observations and studies conducted at the laboratory established by the bureau of chemistry of the Department of Agriculture at Eastport, Maine, during the season of 1913. It does not refer to the packing of sardines in California. The chief factors responsible for the lack of uniform quality in oil and mustard sardines packed on the eastern coast are: Excessive pickling and salting, which removes a large amount of protein material (amino compounds), and lack of attention in securing a uniform degree of salting. Use of fish containing undigested food, particularly "red feed," which is the principal cause of broken and damaged fish. The steaming process, which removes a great deal of salt and flavor from the fish. Insufficient drying of the fish before packing, causing in the finished product a milky appearance of the oil, a slight soapy taste and the fish to be too soft. Variations in the composition of the fish at different times of the year and from different localities, particularly in regard to the fat content. Quantity and quality of oil used. Freezing and thawing of the packed goods. Considering all the possibilities, in connection with this industry, the most important of which is the packing for quality rather than quantity, as is done at present, it is believed that sardines can be produced in this country that are in every respect as good as the foreign sardines.

The Composition and Nutritive Value of the Proprietary Infant Foods: F. C. WEBER AND F. C. COOK.

Chemical, bacteriological and microchemical examinations were made of 36 proprietary infant foods. The nitrogenous constituents were separated and analyses were made of the water extracts and of the ash. The foods, prepared according to the manufacturers' directions for a three-month formula, were analyzed. Charts based on the analyses of the foods and on the three-month formula were prepared and the foods classified according to their composition and method of prepara-

tion for feeding. The results of feeding the three-month mixtures to rats, mice and kittens, and the nutritive value and ratios of these mixtures, were tabulated. The chemical deficiencies and abnormal nutritive ratios in some of the foods are confirmed by the results of the animal-feeding tests. Foods prepared with milk and water give uniformly better results than those prepared with water alone. A comparative study on puppies of the value of lactose and maltose was made.

The Electrical Stimulation of Tissue: OLIVER E. CLOSSON.

In using standardized inductorium for the faradic stimulation of tissue by the break induced shock it was found that the point in the primary circuit where the break is made and the distribution and nature of the resistance must be the same as used in standardizing. Keeping the same resistance in the primary circuit so that the open circuit potential difference and amperage remain unaltered, the position of the secondary in the region 50 cm. from the primary may be made to vary as much as 15 cm. for the same stimulating value by changing the point in the primary circuit where the current is broken or by changing the distribution of the resistance. In the secondary circuit the distribution of the electrical capacity is of very great importance in determining the beta unit of Martin. It is found that the stimulating value is greatest when the distribution of the capacity is such as to produce the greatest fall in the average absolute negative potential (electron potential) of the kathode and anode. The irritability was greatest with an anelectrotonic change, just the opposite to the usual electrotonic findings. It, however, conforms with the findings which point to the kations as being the important factor in stimulation.

A New Apparatus for Determining Crude Fiber in Foods, Feeding-stuffs and Feces: A. D. EMMETT.

In crude fiber determinations, it is often very difficult to transfer the last portion of the insoluble residue from the flask to the Gooch crucible or funnel. The use of the beaker is an advantage, not only from the standpoint of accuracy, but also with respect to the saving of time. The special feature of this apparatus is the arrangement which makes it possible to use a beaker. It consists of a specially constructed glass cone and rubber ring which prevents appreciable loss of water vapor during the boiling and thereby any increase in the concentration of the acid and alkali solutions. The inverted cone is attached to a Hopkins

condenser with rubber tubing and the ring is snapped on to the lower edge of the cone. The condenser, cone and ring are then lowered over a 400 c.c. *lipless* beaker and adjusted until the connection between the rubber ring and beaker is tight. The entire apparatus is fastened in place by the clamp which holds the condenser. The glass cone is provided with a side-tube attachment which is so constructed that when air is drawn through the apparatus gently, the tendency to foam is greatly retarded.

The Carbon Dioxide Excretion as Modified by Body Weight: G. O. HIGLEY.

This work was done with the apparatus described in "The Carbon Dioxide Excretion Resulting from Bicycling," Higley and Bowen, *American Journal of Physiology*, XII., 4, page 311 (1904). There were nineteen subjects, students in the University of Michigan. The subjects, who had been engaged in laboratory work for several hours preceding the experiments, reclined for fifteen minutes preceding the putting on of the mask and the beginning of the record. The average excretion of carbon dioxide per kilogram of body weight was .0063 grams. Wide departures from this value seemed to be due (1) to an excessive amount of adipose tissue in the body of the subject giving low results, and (2) to colds and to indigestion giving high results.

Proteins of the Central Nervous System: H. H. MCGREGOR AND C. G. MACARTHUR.

A study of the proteins of the central nervous system has been conducted by drying the fresh tissue with an air current and removing a large proportion of the lipoids by cold solvents. After this treatment the solubility of the protein in aqueous solutions is found to be greatly increased, and the product precipitated by addition of excess of alcohol contains only slight amounts of lipoids. The protein obtained by this method contains phosphorus and has always given a slight though definite reaction for iron. Whether extracted by distilled water or by salt solutions, the protein is not precipitated upon dilution: the extract therefore contains no true globulin. Treatment with weak acetic acid yields an acid-precipitated and an acid-soluble fraction. The evidence from fractional heat coagulation and fractional salting out points to the individuality of the protein, instead of the presence of a mixture of nucleoprotein and globulin.

Enzymes of the Central Nervous System: H. M. ENGLISH AND C. G. MACARTHUR.

Enzyme extracts were made directly from fresh tissue by water, dilute acids, dilute alkalis, dilute salt and glycerine. After several days' standing with toluol or oil of mustard as a preservative, the extracts were examined. Lipase, peptase, nuclease, proteinase, peroxidase, arbutinase, salolase, dextrinase, were found to be present. Lipase gave activity on the following substances in the following order. Triacetin, monobutyrin, ethyl butyrate, olive oil, kefalin, lecithin. Sodium glycocholate, saponin sodium phosphate, were activators for lipase. The various divisions of the brain contained the same enzymes, but in different amounts. The cerebrum extract was several times as active as that of the medulla. Gray matter is much more active than white matter.

Specificity in the Action of Drugs on Brain and Heart Fosfatids: C. C. MACARTHUR AND G. H. CALDWELL.

If caffeine, cocain, strychnin and other brain drugs show their specificity by some particular effect on brain kefalin and brain lecithin, these drugs ought to change the very sensitive calcium chloride precipitation limit of the fosfatid solution. Many series of determinations gave no such result. Digitalis strofantin (etc.) should effect heart lecithin and heart cuorin solutions in a similar way. No consistent results of this kind were noticed. These results suggest that the fosfatids, in the condition isolated, are not concerned either through their solubilities, through changes in the state of aggregation, or through chemical combination in drug action. Probably these drugs effect more complex combinations or more labile groups of substances than those we isolate.

Reduction Processes in Plant and Soil: M. X. SULLIVAN.

Plant roots possess the power to reduce ammonium molybdate to the blue oxide MO_3O_8 and to reduce a mixture of para-nitroso-dimethyl aniline and alpha naphthol to naphthol blue. The first reduction is favored by a slightly acid medium and occurs predominantly within the parenchyme cells just back of the root tip. It is probably due to nonenzymotic products. The second reduction is not particularly localized; and is retarded by dilute acids, favored by dilute alkalis. Certain solids likewise have the power to form naphthol blue from the mixture of para-nitroso-dimethyl aniline and alpha naphthol. Soils possessing this power do not oxidize easily oxidizable substances such as aloin. Conversely, as far as investigated, soils acting on aloin do not form naphthol blue.

The Passage of Nucleic Acid from Plant to Medium: M. X. SULLIVAN.

In the water in which wheat had grown for sixteen days, with change of water every two days, material was found which was soluble in dilute alkali, precipitated by dilute acids and alcohol, contained phosphorus, gave the pentose reactions and on hydrolysis with dilute acid gave a reducing sugar and xanthine bases such as guanine, determined by color reaction and formation of the hydrochloride, and adenine, determined by color reaction. The material was judged to be nucleic acid.

Chemical Studies upon the Genus Zygodenus: C. L. ALSBERG.

A number of species of plants of the genus *Zygodenus* are regarded as poisonous. Great confusion from the toxicological standpoint has existed in this genus because the nomenclature of this genus has not always been clearly understood. Thus the alkaloids of the "veratrine" group have been misnamed. It is not found at all from species of the genus *Veratrum*. *Veratrum* contains no veratrine, but, as is now well known, is a mixture of quite different alkaloids. The alkaloids of the "veratrine" group are, as is generally known, obtained from sabodilla seeds. These are the seeds of a species of *Zygodenus*. Hunt was the first to show that the *Zygodenus Venenosus* of the western United States contains the same or similar alkaloids. Slade confirmed this and Heyl and his collaborators obtained a crystalline alkaloid, apparently belonging to this group, from *Z. intermedius*. In the investigation herein reported, similar alkaloids were obtained in crystalline form from *Z. Venenosus*, *Z. elegans* and *Z. coloradensis*, all of them very toxic and with similar pharmacological action. From a member of a closely related genus, *Amianthum muscatoxicum*, a similar active principle was obtained in an impure state. Apparently many of the species of this group of lilies contain "veratrine" alkaloids or alkaloids related to it.

Nephelometry in the Study of Nucleases: PHILIP ADOLPH KOBER AND SARA S. GRAVES.

The nephelometer can be used for the study of nucleases, if an acid egg albumin solution is used as a precipitant. This reagent will reveal the presence of one part of yeast nuclei acid in 1,000,000 parts of water, and in practical work is not affected by most substances found in physiological work.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE
ADVANCEMENT OF SCIENCE

Entered in the post-office at Lancaster, Pa., as second class matter.

TERMS OF SUBSCRIPTION

Five dollars annually in advance: single copies, 15 cents. Subscriptions, changes of address and advertisements should be sent to SCIENCE, 41 North Queen Street, Lancaster, Pa., or Sub-station 84, New York, or Garrison, N. Y.

ADVERTISING RATES

One page.....	\$18
Preferred position.....	27
Outside cover.....	36

DISCOUNTS

48 pp.....40	per cent.	2 pp.....25	per cent.

12 pp.....33½	"	½ p.....10	"
6 pp.....30	"	¼ p.....5	"

Published every Friday by
THE SCIENCE PRESS

Lancaster, Pa. Garrison, N. Y.
Sub-Station 84: New York

ELEVENTH EDITION

THE MICROSCOPE,

an introduction to Microscopic Methods and to Histology, by SIMON HENRY GAGE of Cornell University. The 11th edition has eight pages of new matter and corrections, otherwise it is like the 10th ed. Price \$2.00 postpaid.

COMSTOCK PUBLISHING CO., Ithaca, N. Y.

PROVIDENT TEACHERS' AGENCY

120 Tremont Street BOSTON, MASS.

We enroll and we recommend teachers and officers for public and private schools, for normal and technical schools, and for colleges and universities. Vacancies now for immediate service and for 1914-15. Director, JAMES LEE LOVE, formerly of Harvard Faculty.

FOR SALE

Astronomical Telescope—6-inch (Brashear) objective, 90 inch focus, with finder, mounted on iron column having fine adjustment in azimuth—circles reading by vernier to 1 minute, respectively, time and arc—Driving clock, with governors, driven by Weights—Slow motion attachments in both Right Ascension and Declination—Ten eye pieces, with diagonal prisms for both star and solar observations. Price, \$575. Also Fauth micrometer with position circle, \$175.

STEWART & LLOYD, 51 Wall Street, NEW YORK.

Buy Science Apparatus Direct From the Factory

Write for the Chapco Purchase Guide No. 11 and note the remarkable savings on high grade Laboratory Apparatus by dealing with first hands—Prompt shipments. Chapco Apparatus is sold direct from factory to schools. (4)

Chicago Apparatus Co. 55 S. Clinton St. Chicago

Wehrsen Heavy Current Influence Machine

Machine with two 50 cm. revolving disks delivers 600 micro-amperes, with spark 30 cm. long.

Longmans' New Books

Fuel, Solid, Liquid, and Gaseous

By J. S. S. BRAME, F.C.S., Instructor in Chemistry, Royal Naval College, Greenwich, Lecturer on Fuel, Sir John Cass Technical Institute, Aldgate. With 73 Figures and 55 Tables. 8vo. Pp. xvi+372. \$3.50 net (Weight, 34 oz.)

Endeavor has been made in this book to place before the technical man, who is not a fuel specialist, but who requires a good general knowledge of the subject, as full information on all fuels of importance as space permits: at the same time the scientific principles underlying gas producer practice, combustion, etc., have not been neglected. The application of fuels to other purposes has not been overlooked, but primarily fuels are considered in their relation to power. As far as possible the diagrams have been chosen to illustrate principles and typical forms of plant and apparatus.

The Riddle of Mars, the Planet

By C. E. HOUSDEN, Member British Astronomical Association. With 5 Plates (3 Colored). 8vo. \$1.20 net (Weight, 12 oz.)

An endeavor is made to solve the riddle of Mars (of what is possibly happening there) from quite a new direction. The result will, it is hoped, help towards the universal acceptance of the artificial nature of Mars' canals and oases, and all that this implies.

Monographs on Biochemistry

Edited by R. H. A. PLIMMER, D.Sc., and F. G. HOPKINS, F.R.S., D.Sc.

Nucleic Acids. Their Chemical Properties and Physiological Conduct.

By WALTER JONES, Ph.D., Professor of Physiological Chemistry, Johns Hopkins Medical School, Baltimore, Md. Royal 8vo. Pp. viii+118. \$1.10 net (Weight, 14 oz.)

CATALOGUE OF SCIENCE

BOOKS ON REQUEST

Longmans, Green, & Co.

4th Ave. & 30th St., N. Y.

The new Binocular Microscope "Greenough-Leitz" the precision instrument

The "GREENOUGH-LEITZ" is the most accurately and rigidly built binocular microscope on the market.

As there are two tubes containing prisms which reflect the light rays repeatedly in different directions, it is evident that only the greatest care and precision in construction will insure satisfactory results. Spring prism mounting patented.

"Leitz's" are Precision Instruments

The Objectives are excellent, the workmanship exquisite. One great advantage is that the Prism Body and Objectives may be used on a variety of Stands for many purposes.

PRICES ARE VERY REASONABLE

A working laboratory outfit. Duty free, \$54.10 Up
